THIS VOLUME OF "THE GARDEN"

Is dedicated to

LEOPOLD DE ROTHSCHILD,

C.V.O., M.A., D.L., J.P.

WE have much pleasure in dedicating this, the Seventy-seventh Volume of THE GARDEN, to Mr. Leopold de Rothschild, who has given considerable time, thought and encouragement to the advancement of horticulture. He was born on November 22, 1845, and is the third son of Baron Lionel de Rothschild of Gunnersbury Park, Acton, W., and brother of Lord Rothschild and Mr. Alfred de Rothschild. Mr. Leopold de Rothschild is an enthusiastic lover of gardening in all its branches, and has not only almost a passion for landscape gardening, but a practical knowledge of all its details, being ably supported in his love of horticulture by Mrs. Leopold de Rothschild. He was almost, if not actually, the pioneer of Carnation cultivation in pots—notably of the Malmaison type—taking a keen interest in these beautiful flowers before the now popular winter-flowering race was in vogue. His most picturesque, delightful, and one might say romantic, gardens at Ascott, Leighton Buzzard, are his own design. The house itself, when taken possession of nearly forty years ago, was an old farmhouse of the better type; now it is a most extensive residence, but the original style of architecture has been carefully preserved. The house on all sides is well clothed with climbers. The gardens are extensive, and both spring and summer bedding are well carried out. This season a rock garden has been formed. Winter-flowering plants under glass are one of the special features at Ascott, and Carnations, Begonias, Plumbagos, Geraniums and forced Roses are particularly well grown. His gardens at Gunnersbury are also well known, and fruit culture is carried out on an extensive scale, both under glass and in the open. Here the pleasure grounds are very charming, particularly in the summer-time, when they are extensively used for garden-parties and other social functions. Mr. Leopold de Rothschild is a keen lover of country life, and few things afford him greater pleasure than visiting well-known gardens. He is a Vice-president of the Royal Horticultural Society and of other bodies that have for their object the encouragement of horticulture. He was chosen last year as the President of the Jury at the Royal International Horticultural Exhibition. Recently the Veitch Memorial gold medal was awarded to him for his distinguished services in the furtherance of horticulture. This year he presided for the second time at the Festival Dinner of the Gardeners' Royal Benevolent Institution. Gardeners have no greater friend than Mr. Leopold de Rothschild. He is at once in full sympathy with their difficulties and their disappointments.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Office: 29, Tavistock Street, Central Garden, W.C.

NOTES OF THE WEEK.

Treatment of Yew Hedges.—We would remind readers that the present is a good time to attend to Yew hedges, which are not so satisfactory as they should be. A top-dressing of well-trotted manure some 3 inches thick and a foot or 18 inches in width, placed along either side of the hedge and nearly up to the stems of the Yews, will prove highly beneficial during the coming growing season.

Chrysanthemum Godfrey's Perfection.—This recent introduction only requires to be known, and it promises to make an ideal pot plant for the amateur. It belongs to the Anemone-flowered section, and, when fully developed, the flower-heads are quite white. It is a sturdy-habited plant of about three feet high, bushy and free flowering withal.

Succulents in the Edinburgh Royal Botanic Gardens.—The succulent plants in the Royal Botanic Gardens, Edinburgh, are always worth a visit from all interested in these attractive plants. The collection is a very large and well-selected one, including many choice Cereus, Opuntias, Echinocacti, Euphorbias, Haworthias, Stapelias, Huernias, Mesembryanthemums, Aloes and, in fact, all classes in cultivation. The collection is not only very large and well selected, but it is admirably cultivated.

Saxifraga apiculata.—The persistency with which this sturdy yellow-flowered alpine endeavours to flower right through the winter is one of its most remarkable attributes. Frost and storm may appear to repel and mar it every now and again, but it still returns to the charge, and later, in more senses than one, is as a "giant refreshed"; that is to say, its later flowering is its better flowering so far as the open air is concerned. Meanwhile, we may have it and enjoy it in the alpine-house, where it is free to expand its pretty primrose yellow blossoms.

The Laurustinus.—This old favourite shrub is flowering more profusely at the present time than we have ever seen it before. Nearly every outside branch bears a cluster of flowers, opening and in bud. We have seen several division hedges in gardens entirely composed of the Laurustinus, and, owing to good treatment, both the sides and the tops are well covered with flowers. In tubs placed on paths and in other parts of the garden, this shrub is equally well flowered, and in every instance the foliage is luxuriant. Any ordinary garden soil suits this shrub.

Christmas Roses and Hardy Ferns.—In the vicinity of the Cumberland Gate at Kew a wide border is very attractive at the present time by reason of a natural arrangement of Christmas Roses and hardy Ferns, with here and there the marbled foliage of healthy clumps of hardy Cyclamen. The mild weather has resulted in the fronds of the Ferns remaining greener than is usual

for the time of year, hence the white flowers of the Hellebors are prettily contrasted. But even where the fronds are brown, the effect is very pretty, and such grouping might well be copied by people who have a border to plant which is made up of fairly moist soil and is in partial shade, for Christmas Roses like a moist root-run and a certain amount of shade.

The Spurge Laurel (Daphne Laureola).—If this plant were a new introduction, it would be heralded with a flourish of trumpets as an interesting shrub that flowers in the dead of winter. As it is a native of our woods, little heed is taken of its many virtues, and its fragrant, although not showy, flowers come and go unseen save by the few who look for the joys of the country-side at this season of the year. On the chalk hills in Berkshire we recently came across little copses of Hornbeam and counters, in which the Spurge Laurel was flowering freely. It is an excellent shrub for coverts, and is one of the few evergreens that will flourish under the dense shade of trees.

To Our Readers.—With this issue a new volume and a new year commence. It is pleasant to look back upon the year which has just closed, and to recall the kindly feeling that has existed between Editor and readers. To those who have sent us letters of appreciation and notes of interest, and also to those who have so ably assisted us in making THE GARDEN better known, we tender our thanks. Numerous readers have sought advice in difficulties which have beset them in their gardens, and it has been a pleasure to give such advice. We hope in the year that is just starting many more will write to us about their gardens and their difficulties. To all our readers we wish greater success in their gardens than they have ever experienced before. Following our usual custom, we are presenting an almanack with this issue. This gives the dates of the leading horticultural shows to be held during 1913, and we hope it will be hung up as a guide to these events.

A Bright Greenhouse Plant.—Hemanthus multiflorus is a beautiful bulbous plant and one of the most pleasing occupants of the warm greenhouse when in bloom; and, fortunately, it is so amenable to various methods of culture that its flowering period can be extended over a considerable time by the device of prolonging or restricting the resting period. In midwinter its bright red flowers are perhaps more pleasing than at any other period, and they are charming when associated with Ferns or other green-foliated plants. The flowers appear in a large umbel surmounting a stout stalk 12 inches to 18 inches high, and are in advance of the leaves. It is necessary to keep the plant growing in a warm greenhouse or stove until the leaves begin to turn yellow, when water may be gradually withheld until all leaves are dead. Perfect dryness and rest are then necessary for several months, the earlier bulbs being started into growth again in November.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

The Mild Weather.—As your correspondents are showing, this is indeed quite an abnormal season. Here I had Winter Aconites in bloom on November 30. At the present date the ordinary Snowdrops are in full bud. The Cilician type have, of course, been blooming for weeks, and are nearly over. But what to me is even more extraordinary is that not only is *Anemone alpina* up in profusion, but already some of the clumps are flowering!—H. KINGSMILL MOORE, *Cedar Mount, Dundrum, County Dublin.*

A Beautiful Native Tree.—During the early days of May there is no more beautiful sight in this country than the hedges and trees of the native Hawthorn, *Cratægus Oxyacantha*, or May-blossom as the children delight to call it. We often

brightening up a garden. A bright variegated Rock Cress is *Arabis albida aurea variegata*, which has pretty yellow and green leaves. *A. albida argentea variegata* has a similar variegation, but in this case the colours are white and green. *A. alpina flore pleno variegata* is a white and green variegated form of the popular double *Arabis*. *A. lucida variegata* is not so good on dry soil, but is of green, edged with yellow.—S. A.

Lewisias Cotyledon and Howellii.—Your correspondent's notes on these lovely plants on page 635 of the December 21 issue are misleading. The plants are not natives of California, but of cold, wind-swept Alaska, in the Far North. There they make their home in the deep crevices of the rocks in the rough, gravelly soil. That they have been principally supplied through a Californian collector may be the cause of the error as to their habitat. There is no doubt as to their absolute hardiness and easy culture in any deep, well-drained stony

why such a society is desirable. 1. The Daffodil holds the undoubted position of queen of the spring flowers. 2. The Royal Horticultural Society's Narcissus committee has neither the time nor the power to advance the interests of the flower as its merits deserve. 3. The Royal Horticultural Society's Classification List, good though it is, requires revision now, and the constant introduction of new varieties calls for its annual revision. 4. It is desirable that special standards be laid down for the flowers in each class. These would be of assistance to the seedling-raiser as well as to the judges of show flowers. 5. Special rules are required for judges at Daffodil shows. 6. The annual report giving *inter alia* lists of good garden varieties and describing the best novelties of the year would be of value. 7. Investigation of insect pests and diseases is required. I hope that it may be found possible to hold a conference on the question during the forthcoming Daffodil season, and that those "in authority" in the Daffodil world will take the matter in hand.—C. E. KIRCHIN.

The Flower Garden in Winter.—

I would suggest that *Coronilla glauca* might be added to the list on page 639 of THE GARDEN for December 21. In Surrey it seems hardy, having withstood 25° of frost; but, of course, being winter-blooming, the flowers and young growth will be nipped back by such cold. At the end of December I had it in bloom in the open, having withstood 12° of frost without protection. As a plant on a south wall it would only need protection when in full bloom in severe weather. The season of flowering lasts long into the spring. Also *Iris stylosa* should not be forgotten as a cut flower from the open in mild weather from November until April. Many notes have appeared in THE GARDEN about this lovely and easily-grown *Iris*. Although I have grown it for years, I can never make up my mind whether clumps which do not bloom well one winter should be divided up and replanted in spring, or whether, if left alone, they will bloom well another winter after missing a season. Perhaps a real authority like Mr. Dykes can decide this point.—C. G. B.

A BEAUTIFUL SPRING SCENE: HAWTHORN TREES FLOWERING AT BEAUCHIEF ABBEY, NEAR SHEFFIELD. NOW IS THE TIME TO PLANT TREES.

wonder why trees of this are not more freely planted in the less formal parts of the pleasure grounds in place of others which are often quite unsuitable for the positions they fill. That the common Hawthorn can be very effectively grouped, the accompanying illustration will show. This is from a photograph kindly sent us by Mrs. W. Wilson, jun., Horsley Gate, Holmesfield, Sheffield, and represents a scene in the gardens at Beauchief Abbey, near Sheffield. We publish it now while there is time to plant. The tree is not fastidious in its requirements, as we know of examples that are thriving in almost all sand, and others doing equally as well in the heaviest clay.

Variegated Arabises in Winter.—Without professing any great admiration for plants with variegated leaves, one may well find them of considerable value for certain positions and at certain times. In winter they are occasionally of considerable value, as the golden or silver variegated leaves are almost as good as a flower for

soil in a sunny position. Last winter we planted some, just received from a collector, on a new moraine in an especially exposed position, and also on a wall, yet these have done quite as well as the rest, which were carefully potted and protected under glass. They are easy and hardy, and are happy-looking subjects at all times; but are, apparently, so slow-growing that the demand will, I fear, have to be supplied from their native country. My earnest hope is that the supply may prove inexhaustible.—J. STORMONT, *Kirkbride, Carlisle*. [We welcome notes about the cultivation of new plants, as so little is known about the requirements of many of them.—Ed.]

A National Daffodil Society.—In 1910 considerable discussion took place in some of the gardening papers as to the desirability of forming a National Daffodil Society, but although the suggestion met with very general approval, nothing was effected. In venturing once more to raise the question, I should like to advance a few reasons

—Reading an article on this subject, pages 639 and 640, issue December 21, called to mind the following winter-flowering plants: *Lonicera Standishii* and *L. fragrantissima* (for a wall), *Daphne Mezereum* (with its exquisitely-scented blossoms), *Cratægus monogyna præcox* (Glastonbury Thorn), Tree and Bush Ivies, and *Viburnum Tinus* (*Laurustinus*), whose pinkish white flowers and dark green foliage are invaluable for cutting. Then there are many evergreen shrubs with fine berries, such as *Skimmia japonica*, *Escallonia macrantha*, Hollies, of course, *Ruscus aculeatus* (Butcher's Broom), which thrives under the shade and drip of trees. Plants with handsome foliage and stems also help to make a garden interesting during the winter months, and of these I would mention *Yucca gloriosa* (Adam's Needle), *Magnolia grandiflora* (with its shining, russet-backed leaves), *Laurus nobilis* (Sweet Bay), *Megasea cordifolia*, Brooms, and last, but not least, the hoary grey foliage of Lavender and Rosemary and the silvery grey hue of a Carnation bed.—E. G. SHEPLEY, *Ahesford, Hants.*

Winter Aconites Flowering Early.—I think your readers will be interested to hear that ever since the second week in December the woodland glades of the Fellows' Garden of St. John's College, Cambridge, have been carpeted with a sheet of Winter Aconites, hundreds and thousands in full bloom. I have for years kept a careful record of the dates of opening of our earliest flowers, and I have never known these to appear before the last days of the year, and then only as isolated specimens.—M. KENNY, *Westbye, Cambridge.*

Good Red Currants.—No doubt the varieties recommended in THE GARDEN for December 18 are good in a way, but they are all late sorts, and I never could see that La Constante and Versailles were distinct. The fault of these last two is that the branches are very liable to break off from the parent bush, so that it is not easy to get a large bush, such as Raby Castle forms; from this half a bushel has been gathered. My selection would be the varieties Knight's Early for first crop (called Scotch in Kent), New Red Dutch or Chiswick Red for main crop (dark red), and Raby Castle, Scotch-grown Upright, Dutch Spreading and Raby (half-spreading), while for a very late variety Prince of Wales or Rivers' Late is very fine. Fay's Prolific and Versailles are very much alike, and are best on a fence or wall. They are sweeter than the others.—GEORGE BUNYARD.

Ruellia macrantha.—Among the many acanthaceous plants that are of considerable value in a warm greenhouse owing to their winter-flowering qualities, must be included this Ruellia, which came to us from Brazil many years ago. It stands out from all other Acanthads in the size of the individual flowers, these being in vigorous examples nearly four inches long, tunnel-shaped, and well approaching three inches across the expanded mouth. They are of a pleasing rosy red shade, veined in the throat with a deeper colour. This Ruellia is most satisfactory when propagated from cuttings of the young growing shoots in early spring and shifted on during the summer when required. In the warm weather the plants will do well in a frame, shutting them up rather early in order to husband the sun-heat, but exposing them more towards the end of the season.—H. P.

Ferns in Glass Bottles.—It is quite usual for Ferns to appear in glass bottles, as mentioned on page 633 of THE GARDEN for December 21 especially when buried to some depth in the soil. I recollect many years ago seeing a short edging in a small garden which had been formed with empty soda-water bottles, which had been discarded and fixed in the soil, sunk to about two-thirds of their length, and in most of these small Ferns had appeared, mostly Lastreas. It cannot be contended that these sprung from spores conveyed on other Ferns, but the spores must have been in the soil. Since that time I have seen and tried the experiment of sinking broken bottles in the ground, bottom up, leaving a few inches above, and in many of these young Ferns have appeared. The experiment, if such it can now be called, is an interesting one, although I have never seen any but common Lastreas and similar Ferns produced.—S. ARNOTT.

GARDENING ACROSTICS.

AS announced in our issue for December 14, 1912, we are publishing a series of eight acrostics based on gardening or simple botany. Prizes of £3, £2 and £1, respectively, will be awarded to those sending in correct solutions of all the acrostics. The names of those who have correctly solved the problems will be published from week to week, and the final list of prize winners in our issue of February 22. In all cases the Editor's decision must be final. The solution to Acrostic No. 3, which appeared last week, will be published next week, and the solution to No. 4, which is printed below, will be published in our issue dated January 18. For full rules governing the competition readers are referred to page 623 of our issue for December 14, 1912.

DOUBLE ACROSTIC No. 4.

"Hortulanorum Princeps" (properly arranged).

1. A much-abused word.
2. Singers of an "O".
3. The flower Glennie never saw.
4. A "classy" Botanist and Gardener of old.
5. A green circle.
6. Part of a chaplet—a glorious sight in quantity. "In medicine famous and of sovereign use." Say what I am in Latin.

Solutions of the above must be sent so as to reach the Editor at 20, Tavistock Street, Covent Garden, London, W.C., not later than January 11. Mark the envelope "Acrostic" on the upper left-hand corner.

SOLUTION AND NOTES OF ACROSTIC No. 2.

* JOSEPH PAXTON.*

Sir Joseph Paxton was gardener at Chatsworth; Editor of the "Magazine of Botany," begun in 1834 and continued for sixteen volumes; and architect of the building of the Great Exhibition, for which he was knighted—"History of Gardening in England," third edition, page 296.

- * 1. J. P.
- † 2. O SMUND A
- ‡ 3. S PADI X
- § 4. E SCHALO T
- ¶ 5. P OTAT O
- ‡ 6. H OXTO N

* John Parkinson.—Johnson's "History of English Gardening," page 82. Parkinson wrote the "Paradisus" and also the "Theatrum Botanicum," 1640—"The most extensive Botanical work then extant." † The Osmunda is "the Royal Fern"; it is dedicated to St. Christopher.—Friend's "Flowers and Flower Lore," page 158. There is only one species of Osmunda in England. ‡ The centre of the so-called Arum Flower is called a spadix. § A. Dean's "Root and Stem Vegetables," page 37. It is often spelt Shallot, e.g., in Weathers' "Garden Guide." ¶ Messrs. Sutton and Sons and others are trying to obtain such a tuber. † T. Fairchild had a vineyard at Hoxton as late as 1722.—Johnson's "History of English Gardening," page 191.

SOLVERS OF ACROSTIC No. 1.

CORRECT solutions of Acrostic No. 1, published in our issue for December 14, 1912, were sent in by the following: "S. W.," "Brixtonian," W. Bond, Frederick Marshall, James Clayton, Miss L. Joshua, R. Chapman, H. A. Churchill, Mrs. C. J. Clerk, "Nedrag," Ernest Walker, "Omega," Mrs. L. Patterson, F. W. Hull, "Tempus Fugit," F. Bloomer, Miss N. Lucas, "Arlesey," Agatha Mayo, Miss G. H.

Jettreys, E. B. Anderson, "Ubuque," Thomas D. Taylor, "Tide," "Elm, Wisbech," Dr. C. G. Cooper, H. C. Hislop, "Rushmore," Mrs. Prudeaux, S. W. Philpott, "Arnold," Mrs. L. S. Robertson, Mrs. Fitz Hugh, I. Bigg-Wither, Margaret E. Ewbank, B. Newell, "Penwarne," "H. G.," "Witton," "Newton," A. J. Rennie, Frank Mark, "Iris," Walter D. Cartwright, Bruce Barron, Gertrude I. Simms, E. S. Lyttel, "Bob," "Muggins," M. Brown, "Rag," Mrs. Palmes, "D. T.," I. A. Londen, H. Garner, "W. C. E.," "Ping," "Judith," R. W. Dean, Mrs. Florence Jones, "Chum," Miss Hay, H. Tomalin, Miss Pittis, "Anna Olivier," "Ardenmore," Miss G. M. Hollowes, "White Lady," "Roco," W. H. Chapman, "Sen-lae," James Shearer, "Salnod," "Briar Bank," "Watteau," "Elm, Brompton," D. Grant, William Holton, "Nemo," "Boronia," "Huxham," "George," "Arcthusa," "San-tau," "R. P. B.," "G. B. B.," "Lonsdale," "Ivy," "Leander," William Ackworth, A. C. Carne, "Yeltsa," William Slocombe, Alex. Henderson, Lilla Dance, "Glevam," "A. A. T.," "Cycle-car," "Traveller's Joy," Mrs. H. Jenner, "E. Key," "A. B. C.," James Gilchrist, E. Beeson, W. P. Wood, "Boschetto," "Agrostis," Lionel Combes, J. Duguid, W. H. Mothersole and "Vic."

* * * The names of those who have correctly solved No. 2 will be given next week.

PRIZES FOR THE BEST ROCK GARDENS.

To further stimulate the interest that is being taken in rock gardens, the Proprietors of THE GARDEN offer the following prizes for three photographs of a rock garden, or portions of a rock garden:

- First prize: Five Guineas, or a Silver Cup of that value.**
- Second prize: Two Guineas, or Books of that value.**
- Third prize: One Guinea.**

The competition is open only to the actual owner of the rock garden, or to his or her gardener. The object is to encourage good rock gardening, and preference will, therefore, be given to those rock gardens which show originality in design, and where the plants depicted are well grown. It should be distinctly understood that awards will be made to the best rock gardens, and not necessarily to the best photographs. The photographs need not be taken by the competitor, who must, however, in such cases have the written consent of the photographer for their reproduction in THE GARDEN. The competition is subject to the following rules:

1. Not more than three photographs of each garden may be sent in by one competitor.
2. Each photograph must have the full name and address of the competitor plainly written on the back in ink.
3. Successful competitors shall furnish written particulars of the rock garden forming the subject of their photographs.
4. Glazed and mounted P.O.P. prints must be sent.
5. All photographs must be sent to arrive at THE GARDEN Offices, 20, Tavistock Street, Strand, W.C., not later than June 1, 1913.
6. Unsuccessful photographs sent in will be returned if a sufficiently stamped and addressed envelope or wrapper is enclosed, but no responsibility will be taken for the loss or damage of photographs submitted, although every care will be taken of them.
7. The Proprietors of THE GARDEN reserve to themselves the right to reproduce any photograph sent in for competition.
8. The decision of the Editor will be final.

FORTHCOMING EVENTS.

January 6.—Royal Horticultural Society's Examination for Employés in Public Parks and Gardens, 10 a.m.

January 7.—Royal Horticultural Society's Exhibition at Vincent Square, 1 p.m. to 5 p.m.

January 8.—East Anglian Horticultural Club Meeting.

THE FRUIT GARDEN.

CORDON PEAR TREES FOR ARBOURS, PERGOLAS OR WALLS.

THE pergola furnished with Roses and other beautiful climbing flowering plants has had a run of great success and popularity for some years. Why not give the Pear tree a more extended trial in the same way? The summer charm of the two subjects cannot, of course, be compared, and yet, in many respects, the claims of the Pear to popularity as a subject for planting in this way is undeniable. In early spring, as the accompanying illustration so well shows, it forms an object of beauty and interest which always commands and receives unstinted praise and admiration. The glossy and handsome foliage of the trees is always pleasant to look upon, and, framed thus, affords welcome shade in hot weather.

by reason of the limited space they occupy and the large return of fruit they are capable of giving. Another advantage the cordon-trained tree possesses is that it enables the owner to enjoy quite an interesting collection of varieties in a garden of small dimensions.

Position. This is an important matter which must not be forgotten, namely, that the trees must have full exposure to light and air all day long, and shelter from north and east winds, if possible.

Cultivation.—The Pear will succeed in any ordinarily good garden soil that is well drained, but prefers a deep, loamy soil of rather a heavy texture. It is essential to consider the character of the stock on which the trees are worked in relation to the soil in which they are to be planted. If the soil is a rich and deep loam, it would be a mistake to plant cordons worked on the Pear stock there, as the growth would be so vigorous

stock, strike down deeply into the ground for sustenance.

Preparation of the Soil.—Before planting takes place the soil should be deeply trenched and well stirred, but the bottom poor soil must not be brought to the top. It is a mistake to add organic manure to the soil at the time of planting, for the reason that it encourages, especially in young trees, too coarse and strong a growth of branches, which it will be found difficult to ripen, and in consequence will prove barren. The grower's aim should be to encourage a moderately strong growth only, so that its ripening can be assured; and there is no better way of doing this than by adding a barrow-load of good fibrous loamy soil to the soil of each tree, and where the soil is at all poor add a quart of bone-meal, well mixing it with the soil at the time of planting.

Planting.—Avoid planting deeply, especially on heavy, cold soils. It is a safe practice to follow to make sure that the top layer of roots, after the planting is completed, is not more than 5 inches below the surface of the soil. Do not plant if you can help it when the soil is sticky and wet, but choose a time when it is fairly dry. Do not let the roots of the trees be exposed to the air without cover for a moment longer than can be helped. Spread out the main roots evenly and carefully before covering with soil, serving each successive layer the same until the last layer is laid under, and, lastly, tread down the soil over the roots as firmly as possible and give a good watering if the soil is at all dry.

The Best Trees.—Three year old trees are the best to plant. A few fruit-spurs will have been formed at the base of these from which one or two fruits to a tree may be taken, without harm being done, the first year. Where it is desired that a large space of bare wall or pergola should be furnished with trees in a short space of time, there is no other form of trained fruit tree which can be used to so good an advantage. Trees from six to eight years old may safely and successfully be planted, and a space of from 7 feet to 9 feet thus covered in one season.

BEAUTY AND UTILITY: PEAR TREES CLOTHING A PERGOLA IN A KITCHEN GARDEN.

Not the least enjoyment of a garden in summer is the pleasure of watching the young fruit grow, while autumn brings with it not only the beauty of the ripening foliage in its varied and rich colouring, but also the substantial and generous return of a good crop of sweet and luscious fruit.

Of all hardy fruit trees the Pear is best suited for this way of training; its young shoots in summer are so pliable that they may be trained to any shape desired. As the accompanying illustration shows, the manner of construction is very simple and easy. The base of the work, however, must be so firm, and the material of which the structure is made—whether of iron or wood—so strong, as to safely resist wind pressure. Other purposes for which cordon Pear trees are well suited are for covering wall spaces quickly, or for profitably hiding ugly corners of the garden in summer. For small gardens they are a blessing without the disguise,

that it would be found impossible to properly ripen it in ordinary seasons, especially that on young trees; therefore no fruit-buds would be formed and the trees would be barren. Thus trees worked on the Quince stock only should be planted on soil of this nature, because the roots of the Quince are of a more fibrous nature and remain near the surface of the ground, where they will not only derive all the benefit of this better soil, but also be where they are accessible to the benefits to be obtained from summer mulchings of manure placed on the surface of the soil over their roots. Trees bear crops much younger when worked on this stock than on the Pear. On the other hand, where the soil is comparatively poor and not of great depth, trees on the Pear stock should be planted, as they will not grow so strongly, and consequently the wood they make is easier ripened, and in case of drought they would suffer no ill-effect, as the roots of the Pear, when grown on this

Pruning After Planting.—Judging from the number of enquiries received on this point, one would think that the pruning of a Pear or any other fruit tree was one of the most mysterious and unattainable of objects, a sort of sealed book, to be read only by the expert. It is really nothing of the sort, but is most simple and interesting work. The most important thing to remember in starting on the winter pruning of the Pear tree is that in ordinary pruning no shoots are to be cut in any shape or form other than the shoots of the past summer's growth, and these always consist, in the case of the cordon, of side and terminal shoots. Let every one of these be cut back, the side shoots, in the case of the weakest, to within two buds of their base, and the strongest to within three buds of their base, the terminal or leading shoot (of last summer's growth), supposing it is 3 feet long, to be pruned back to half its length. If it should be 2 feet long, 9 inches only should be cut off, and if it is only

1 foot or 15 inches long, then no shortening is required. The Pear seldom if ever bears on one year old wood, and the object the pruner has in view in cutting the shoots so hard back is for the purpose of encouraging the formation of fruit-spurs at the base of the shoots so cut back.

Summer Pruning, which in the case of the cordon tree is of much more importance than winter pruning, will be referred to again nearer the time it will need attention.

The Best Varieties.—The following sixteen varieties, which are arranged in the order of ripening, will be found among the best, and are good, healthy growers. A few trees of each should secure a good succession of ripe Pears from summer to spring. The very earliest ones are scarcely worth planting, especially in small gardens, as they are available for use for so short a time: Beurre Giffard (ripe in August), Williams' Bon Chrétien (September), Triomphe de Vienne (September), Conference (October and November), Louise Bonne of Jersey (October and November), Marie Louise (October and November), Doyenné du Comre (October and November)—plant most of this, as it is the best), Emile d'Heyst (October and November), Glou Morceau (about Christmas), Winter Nelis (about Christmas), Santa Clans (about Christmas), Bleckling (January and February), Bergamotte Esperen (January and February), Nouvelle Fulvie (January and February), Le Lectier (January and February), and Duchesse de Bordeaux (March to May)

OWEN THOMAS, V.M.H.

ANNUAL FLOWERS IN THE KITCHEN GARDEN.

IT has long been a source of wonder to me that more use is not made in the kitchen garden of the many beautiful annual flowers that are available. In many large establishments it is customary to flank the paths in the kitchen garden with a narrow or broad border of herbaceous flowers, a practice which has much to commend it. Not only is the whole garden made more attractive, but such borders provide an abundance of flowers for cutting—a very important item where large quantities are required.

In gardens of more modest dimensions, however, such borders are not practicable; they would encroach far too much on the space that is required for the more utilitarian vegetables, and consequently in such kitchen gardens flowers are, to use a well-known aphorism, too often conspicuous by their absence. Here it is that our annual flowers should be made to play an important part, and one that, if carried out with reasonable care, will give a great deal of pleasure for a very insignificant outlay of time and money. In most small kitchen gardens it is usual to find either bush or

espalier fruit trees near the pathways, and not infrequently these come close up to the edge of the path. When, however, the much better plan of setting them back about two feet from the pathway is adopted, room is left for an edging of flowers that may be anything from 1 foot to 18 inches in width, and here it is that we can put our annuals to good account. The accompanying illustration will give a fairly clear idea of what I mean. In April of last year the seed of the Candytuft was thinly sown in a drill 9 inches wide, and when fully grown produced the effect seen in the illustration. Owing to the thin sowing, no thinning of the seedlings was necessary, and, beyond weeding, the plants required no attention whatever. The pathway shown is

A BROAD EDGING OF ANNUAL CANDYTUFT SNOWFLAKE IN A SMALL KITCHEN GARDEN.

about one hundred and fifty feet long, and the cost of the floral edging was 6d., the Candytuft being the variety known as Webb's Snowflake. This is remarkably free flowering and excellent for cutting, and possesses the additional merit of lasting in bloom for about seven weeks in a summer such as was experienced last year. Even before the plants flowered they formed a neat edging and added not a little to the general tidiness of the kitchen garden.

To carry the idea of such edgings in small gardens a little further, we might very well plant the margins of the paths in autumn with the earlier-flowering Daffodils, allowing them rather more room than

usual; then early in May, when the foliage is declining, stir up the soil and sow our annuals between the Daffodils. Such a procedure would not harm either of the flowers, and would render small kitchen gardens far more attractive than we usually find them.

There are, of course, a great many annuals suitable for the purpose, but in all cases I would emphasize the necessity for having a good broad belt of one kind. A narrow edging to a long path looks lost, while a mixture of *kinds* is not to be commended. On the other hand, a good mixture of colours of one kind of plant, such, for example, as Candytuft or Virginian Stock, may be used with good effect, but do not sow a few yards of Candytuft, a few of Virginian Stock and a few of something else. Generally speaking, an annual with showy flowers should also be selected, particularly where the path is a long one. A few kinds, in addition to those already named, that occur to mind as being suitable, and which may be sown where they are to flower, are Sweet Alyssum, Swan River Daisy, Pot Marigold, Godetias, Linum grandiflorum rubrum, Lupines of the nanus set, Dwarf Nasturtiums and Viscaria cardinalis. If a prominent edging is not desired, the ever-welcome Alphonette may be used, but at a distance it does not produce a very good effect. This is, however, largely compensated by its delightful fragrance. H. H.

TWO EARLY ENGLISH FLOWER BOOKS.

(Continued from page 652, Vol. LXXVI.)

I DO not know how far I am right or wrong, but it seems to me that Samuel Gilbert may almost be regarded as the interpreter and populariser of Rea, in much the same manner as Kingsley in another sphere and in more modern times is said to have performed like offices for Maurice. For one thing, his "Vade Mecum" was a very much smaller work than the "Flora," and consequently it must have been obtainable at a much lower price. Then he tells us in his preface of his intention to avoid "Bombastick" words and "useless notions," and that he was going to write "plain English" as his tract was "really designed for the benefit of the meanest Florist." It is, in fact, almost entirely a flower book, as only in the Monthly Directions at the end are the work and plants of the orchard and kitchen garden mentioned, his reason for confining himself to floriculture being that fruit trees had been "well done by Mr. Langford in a pocket volume of easy price." In this his opinion coincides with that of the famous John Evelyn, who writes of this work "as I know nothing extant that exceeds it, so nor do I of anything which needs be added to it" (Evelyn's introductory letter

in the 1696 edition). The author was a clergyman, being Rector of Quatt in Shropshire and Chaplain to Jane, wife of Charles, the fourth Baron Gerard. According to Harwood's edition of "Edswick's Antiquities of Shropshire," he also practised as a physician. It was doubtless in this capacity that he published in 1676 "Fons Santas, or the Healing Spring at Willowbridge in Shropshire." The double calling was not uncommon in these early times, and with communication slow and a country thinly populated, it is easy to see the utility of such an arrangement. As I have already mentioned, Gilbert married Kea's daughter, Mmerva, and he appears to have lived for the greater part of it not his entire married life with his father-in-law at Kulet, near Bewdley. He had one son and four or five daughters. He probably died about 1692 to 1694. To the garden-lover he is known as the author of "The Florist's Vade Mecum," a small 12mo manual, with which, in the 1683 or first edition, was bound up his "Gardener's Almanack" to last from 1683 to 1687. It also contained his portrait. The work passed through several editions; according to the "Dictionary of National Biography" they appeared in 1690, 1693, 1702 and 1713. My own copy bears the date 1693, and is called "The Second Edition Corrected." This is the copy whose pages we are going to turn over. But before I begin, in order to bring home to my readers the estimation in which this little book must have been held, I would mention that I possess *the first and second editions* of "The Complete Florist, or the Lady and Gentleman's Recreation in the Flower Garden," which is nothing but a very obvious plagiarism of the "Vade Mecum."

As might naturally be expected, Gilbert makes considerable use of his father-in-law's "Flora," but there is no slavish imitation. His work appears to be very much his own, in arrangement, in feeling, in composition and in style. He is always letting off steam in some quaint poetic effusion:

"The Daffodils are by the Curious
(Whether Legitimate or spurious)
Accounted beauties in their time,
Deserving notice in our Rhime,
But since 'tis here so poorly done,
They hang their heads, ashamed to own
What so much flats their reputation;
Such Limping-linguade commendation;
Tost Honour loose; with yellow Jealousie
Letting tall to the earth and mourning die."

The flowers are arranged in the sequence of their "blowing." Each month as it were takes under its wing the particular ones which should be in season then. The following are those to which most space is devoted, and accordingly may be claimed as the most popular ones at the time the book was first published: Crocuses (some twenty varieties), Primroses, Hepaticas, Hyacinthus, Bear's Ears (double and single), Tulips, Fritillaries, Anemones, Stock-Gallflowers, Rammulbuses, ²Primes, ²Roses, Lilies, Mays, July-flowers, Jasmines, Flower gentles, Colchicums and various "greens," such as the Orange and the "Mirtle." Of these, as being the most popular of all I would single out Tulips, Anemulas or Bear's Ears, Anemones and July flowers or Carnations. This selection is borne out by those which are generally mentioned in "The English Gardener," a contemporary work by one Leonard Meager, who, when he wrote, had been thirty years a "Practitioner in the Art of Gardening." July-flowers and Bear's Ears ran Tulips very hard in popular favour. Gilbert says, "Caryophyllus hortensis, called July flowers from the month they blow in, and are indeed the Summer's glory as

Tulps the pride of Spring, deserv'ng a Flowerist's care in their propagation and preservation, especially the nobler forms, which are called the Dutch-July-flowers or, more vulgarly, Carnations." Roses are said to be "one of the chiefest ornaments that enrich our Gardens." Thirty varieties are noted and described, and there are hints on budding and various points of culture.

"Who would not then these sweet-leaved flow'rs esteeme
So rare, when either felt, or smelt, or seen?"

Directions are given for making a hot-bed, and the necessity of having a summer-house is insisted upon in a rather long piece of poetry, in which he moralises and bids us

"ourSelves as Gardens keep;
Pluck up the Weeds of Sin, soon as they peep."

The last few pages are taken up with "Monthly Directions what ought to be done both in the Kitchen and Flower-Garden for ever." Here we have the most interesting part in the whole book. As an introduction to what is to follow, two pages of astrological gardening are inserted. Arranged under ten heads (elaborate instructions are given as to when certain operations should be done or when they should not be attempted) (1c). 2. Trees are not to be grafted the moon waning or not to be seen. 3. Sow or plant when the moon is in Taurus, Virgo or Scorpio and in good aspect of Saturn. 8. Set, cut or sow what you would have speedily shoot out again or spring and grow, in the increase of the moon.

One wonders how a man could do so who gives such reliable hints on culture as those, for example, of the Fritillary: "It loses its fibres like the Tulip when the stalk dies down," and it must not be kept out of the ground "longer than August lest thereby the roots perish or be much weakened by it." There is not a single word about the moon or any of the planets until we come to the "Directions." There was not a hint of any such thing in Kea. How came it that they are now inserted in the "Vade Mecum"? To an only presume Gilbert was carrying out what he had previously written and what I quoted in my last article about "Jackanapes on Grant's shoulders." Owing to the writings of several foreign botanists and doctors, and probably in our own land, more especially to those of Culpeper (1616-1654) in his "Physical Directory," the idea that the planets exercised an influence upon plant-life gained wide credence in the latter part of the seventeenth century. The subject is one of much interest. All that I can do now is to suggest that certain gardeners—Gilbert among the number—thought that there might be something in it, and, in case there was, took the precaution of giving a few of the leading principles of the then fashionable theory. Meager, before referred to, says: "Perhaps it might be expected by some that I should say something as to the observation of the moon in sowing, planting, grafting and pruning. . . assuredly notwithstanding the best of my diligence I have not had always like success when-ever the fault was; but I shall set down a little what some others have writ concerning the observation of the moon." The same idea may have occurred to our author. He would be on the safe side if he, too, included a little of what others had written about the moon and planets, but I do not believe he followed them himself. I trust I may have stimulated the curiosity of some of my readers sufficiently to make them wish for more detailed information about the contents of these two old flower books. JOSEPH FAVOR.

THE GREENHOUSE.

WINTER-FLOWERING BEGONIAS.

IT is now many years since the conjunction of the distinct *Begonia socotrana* and some members of the tuberous-rooted section gave rise to quite a new race of winter-flowering Begonias, which rapidly made headway in popular favour. In nearly all the earlier examples, however, the flowers are of some shade of carmine; but last year Messrs. Veitch showed some forms, all with single flowers, characterised by unusual vigour, large-sized blooms and, above all, by the distinct shades of orange and rose represented among them. This class has received further additions during the present season. Though fairly well acquainted with these Begonias, a splendid group put up by Messrs. Chibran of Altrincham at the Royal Horticultural Hall on November 19 contained some eye-openers. The flowers of many of their varieties are perfectly double and of different shades of colour, the pink, warm salmon and orange tones being particularly striking among the varieties that are now being distributed. Four were given awards of merit, namely, Lucy Chibran (budd salmon, suffused orange), and three quite new forms—Eclipse (salmon red), Scarlet Beauty (bright scarlet), and Splendour (rich crimson-scarlet). All of these have semi-double flowers. This group also contained some small seedlings, which, though considered to be insufficiently developed to place before the floral committee, aroused a deal of interest among the specialists present. The flowers of some of these were large, perfectly double and of an intense crimson colour. Not only are the members of this section valuable for their own intrinsic merit, but as the harbingers of a new race they are doubly welcome, and we shall doubtless soon see the members of this section within close comparison of the summer-flowering kinds. The later novelties show a greater vigour than we have hitherto obtained among the *socotrana* hybrids. H. P.

A GRAND WINTER-FLOWERING ORCHID.

(*ANGRECOM SESQUIPEDALE*.)

THE chief interest in this remarkable Orchid is centred in its ivory white flowers, each with a long tail-like spur. In some *Angraecums* the spurs are coiled as in *A. Kotschyi*, which invariably has two spiral twists in each of its whip-like spurs. In the species under notice the spurs are not twisted, but their length—usually from 10 inches to 18 inches—appears out of all proportion to the size of the flowers. The spurs contain nectar, but only very long-tongued insects, such as some of the tropical moths, could ever hope to reach it by way of the labellum.

Plants under cultivation produce their flowers from November till January, and the flowers last some weeks—a point of some importance at this time of year. The leaves are evergreen and produced in two opposite rows, while roots are emitted from the stem—a common occurrence among epiphytal Orchids.

This *Angraecum* could only be successfully grown in a warm house or stove in which a winter temperature of about 60° Fahr. is maintained. A suitable rooting medium comprises a mixture of crocks, charcoal and sphagnum moss, a dressing of fresh sphagnum moss being arranged, cone-shaped, around the stem. *Angraecum sesquipedale* was introduced from Madagascar in 1823.

COLOURED PLATE.

PLATE 1462

ANNUALS AS GREENHOUSE PLANTS.

DURING recent years a great deal of attention has been given to the cultivation of annual flowers as greenhouse plants. Their simple cultivation, low cost and inimitable beauty when in flower demand that they should be much more widely grown in this way than they are at present. Thanks to the efforts of Messrs. Sutton and Sons, who have for some years past made a wonderful display of pot-grown annuals at the Temple Show, and last year at the Great International Exhibition, their value for the greenhouse is becoming widely recognised.

To those who have not seen the displays mentioned, the coloured plate presented with this issue will convey some idea, at least, of the beautiful effect obtainable from plants that are too often and erroneously looked upon as common denizens of the outdoor garden. The plate has been prepared from a colour photograph taken in the conservatory at Mr. Leonard Sutton's private residence. The conservatory is quite an ordinary structure, and is never heated to any great extent. We mention this because many people seem to imagine that elaborate heating arrangements and special houses are necessary for the successful cultivation of annuals in pots. The following cultural details have been kindly sent us by Mr. Sutton's head-gardener, who is responsible for the cultivation of the plants shown in the coloured plate: "When once the full value of annuals becomes known, I feel sure they will rank first and foremost among our greenhouse flowering plants — first, because their cost is very trifling; secondly, they provide a brilliancy of colour and wealth of bloom that cannot be equalled by any other class of flower in such a short period; and, thirdly, they require so very little heat—in fact, the cooler they are grown, the better the results. For example, Clarkias (the elegans class), Alonsoa Mutisi, Nemesises, Lobelia, Phlox Purity, Antirrhinums and Anchusas, nearly all of which will be seen in the coloured illustration, were, with one exception, sown in the months of January and February.

The cultivation of these annuals in pots is easy, because they all need practically the same treatment, the same compost and the same temperature. Take, for instance, the Clarkias shown at the Temple Show. Seed of these is generally sown during September, but good specimens, such as are seen in the illustration, may be had from seed sown as late as February. The seed is sown in shallow

boxes and placed in a cool house. As soon as the seedlings are fit to handle, prick them off in shallow boxes 3 inches apart, and when they have made two or three pairs of leaves, nip out the points of the growths; this will induce them to break and make fine bushy plants. Later, pot singly into middle 60's, and on reaching the height of about nine inches, again remove just the points. For the final potting into 6-inch or 8-inch pots the soil should consist of two-thirds good loam, broken up, and one-third leaf-mould, with an addition of a little soot and bone-meal. Water carefully until the plants are well rooted. The best varieties for pot culture are Sutton's Scarlet Beauty (the brightest coloured of all Clarkias),

similar to that given for the Clarkia, for the final potting using 4½-inch or 6-inch pots.

Phlox Purity is a beautiful pure white perpetual-flowering Phlox for the greenhouse. It makes a charming pot plant, and the fact of its being sweet-scented makes it all the more welcome. Seedlings from a September sowing, grown in cool frames and finally potted into 4½-inch pots, will be in full flower in May. A batch from a February or March sowing will commence flowering in June. Antirrhinums, as we all know, are really hardy perennials, but when once their full value becomes known as annuals in pots for the decoration of the conservatory, they will be in as much demand as the Clarkias. The cultural treatment is exactly

the same as advised for Clarkias, with the exception that they do not require pinching. Such varieties as Sutton's Tall Cloth of Gold, Pure White and Tall Golden Chamions, Intermediate Fir-King, Delicate Pink, and Cord Red, when once seen grown under glass, are a sight not to be forgotten.

Nemesises are beautiful South African annuals that make exceedingly pretty pot plants with their diversity of colouring and floriferous character. Nemesises are splendidly adapted for grouping by themselves in the conservatory, or for use in the mixed greenhouse, as will be seen in the coloured plate. Sow seed in shallow boxes during February, keeping in gentle heat until the seedlings are large enough to handle, when they should be pricked off and gradually hardened. It is a mistake to keep them in a high temperature. Later, pot singly into small 60-sized pots and place close to the glass. When fairly rooted, pot in large 60 or 48 sized pots, in which they will flower. The compost for this potting should consist of two-thirds good loam, broken up, and one-third leaf-mould, with an addition of coarse silver sand, wood-ashes and bone-meal. Remove to a cool frame and keep close for a period until root-action again commences. Afterwards gradually harden by giving air until the lights can be removed altogether. The cooler the treatment Nemesises are given, the dwarfier and more bushy will be the plants. The best varieties for pot culture are Sutton's Large-flowered in separate colours, such as Pale Yellow, Rose Pink, Crimson, Rich Orange, White and Scarlet."

A WELL-GROWN PLANT OF AN INTERESTING AND BEAUTIFUL MADAGASCAR ORCHID (ANGRAECUM SESQUIPEDALE).

Sutton's Early (vivid scarlet-crimson flowers, the long, graceful sprays lending themselves admirably for vase-decoration), Double Salmon, and Sutton's Snowball (pure white flowers and exceptionally double).

Alonsoa Mutisi and A Warszewiczii compacta make charming subjects for greenhouse decoration, the former having delicate pink flowers, each with a deep crimson centre, while the latter has racemes of bright scarlet flowers and dark green foliage. Seeds of these may be sown during September and gently grown on, and some more for a later batch in February. The cultural treatment is exactly

A USEFUL GREENHOUSE CLIMBER.

LANTANA SAVATIFOLIA has considerable merit as a climbing plant for the greenhouse, though it is very seldom employed in this way. It is of a tree habit of growth, and if the main branches are secured to a roof or rafter, the long, slender shoots hang down for a considerable distance. The flowers, which are, as in the other Lantanas, in rounded heads, are of a blue colour, and borne for a considerable distance along the shoots. H. P.

GARDENS OF TO-DAY.

WARTER PRIORY, YORK.

ON the Yorkshire Wolds, some 800 feet above sea-level, are situated some of the most extensive and beautiful gardens that can be found in the country. Anyone visiting those at Warter Priory, which belong to the Dowager-Lady Nunburnholme, have no need to be reminded that the owner—besides being an architect of no mean order—is a most enthusiastic and clever gardener, for here originality proclaims itself on every side.

The Priory and its grounds are surrounded by densely-wooded hills and verdure-clad dales. An adequate water supply is obtained from numerous springs in the hillsides; hence the name of Warter, which was formerly spelt in the orthodox way.

From the mansion one sees goodly stretches of velvety lawn connected by bold terraces, with

companion, the cottage garden (a most original feature—see illustration on page 9), complete with a tea-house of the Gothic style and a delightful wishing-well almost encompassed with Rosemary, Lavender and various twining plants.

From a somewhat elevated point close by we view along dry wall, divided at suitable distances by wide steps, or, to be precise, rough-hewn stepping-stones, the whole overgrown by alpines in Nature's own way. Here, too, we get our first glimpse of the rock and water garden, and as we take our steps along the rippling, tumbling, sometimes rushing stream, we cross and recross at our leisure to admire the endless variety of flowers and plants on either side. We marvel at the combination of colour, and at length come to the cascade and watch the water-wagtails dart beneath the showers of spray as the water tumbles over the rocks into the turmoil below. We are loth to leave such a scene, but must needs follow our guide through the quite recently made wild garden and dry tennis court to the gardens across the park.

Cypripediums, Begonias, Bouvardias, Pancratiums, Camellias, Liliums, Callas, Plumbagoes, Pelargoniums, Cinerarias, Primulas, and quite a host of decorative and exhibition Chrysanthemums.

Fruit is well represented at Warter Priory. There are ideal vinerias, and the Vines raised from eyes over two years ago produce large, shapely bunches of Grapes. Peaches, Nectarines, Figs, Cherries, Plums, Apricots and Melons are grown in quantity under glass, and Apples and Pears are included in the pot fruits.

Our guide leads us along a winding leafy drive, which brings us to the picturesque village of Warter. Here one sees well-tended gardens with a choice collection of plants seldom met with in cottagers' gardens. Prizes are awarded annually for the most effective cottage gardens.

Another short, steep drive to the south of the Priory, and we suddenly enter the snug little village of Nunburnholme, asleep—so to speak—to the rest of the Wolds. From here we turn our faces homeward with the unspoken, but none the less sincere, wish that the lady whose gardens have given us such pleasure may live long to promote the noble art of gardening.
Walton, Warwick. SIDNEY LEGG.

A HOUSE OF GARDENIAS AT WARTER PRIORY, YORK

ornamental stone walls covered with Roses and various creepers, which, in summer and early autumn, are ablaze with colour. As we ramble through a fine old rustic pergola we come to the Italian garden, with its wealth of bloom, statuary and fine topiary work. Of special interest at this point is a broad flagged path, considerably more than a hundred yards long, parallel to which, but separated by informal beds, runs a fine Rose hedge of the old and well-known variety Fellenberg. To the south-west of this is a carefully-planned and charmingly-situated reclus, in the centre of which stands a massive Italian well-top, brought by the owner from Italy.

We proceed by way of the lake, well stocked with golden trout and furnished with water plants, through the Rose garden, resplendent with large beds of sterling varieties to the spacious Dutch garden, with its quaint ornaments. We then come to the greatly-admired sink garden and its

On entering the kitchen garden we meet with another surprise. Besides most worthy examples of fruit and vegetables we espy a harvest of flowers on all sides—borders of Roses, Carnations, Chrysanthemums, Pansy Dahlias, annuals, herbaceous plants and half an acre of Sweet Peas. All these are grown, we are told, for the embellishment of the mansion. A large supply is needed for this purpose throughout the year. The newly-built glass-houses are numerous, and the fruit and flowers grown therein are—as is vegetation in all other departments—brought to a high standard of excellence. It is no wonder that such an all-round gardener as the superintendent, Mr. F. Jordan, is often seen judging at the leading horticultural exhibitions.

About five thousand Tree and Malmeson Carnations are grown, and among other things are quantities of Foxgloves, Gardenias, Gesneras, Euphorbias, Cyclamen, Cattiveas, Calanthes,

opening out into flowers that resemble that beautiful Tea Mme. Antoinette. It is a midseason rather than an early flowerer; its only fault is that so far one would not call it particularly free flowering, but I do not think, when it has become established, one would have to find fault with it on that account. Sweet-scented, bright rosy carmine outside petal, fading into a bluish flesh in the large open flower. Those who have not got it should certainly try it; it has been very much admired here.

Sarah Bernhardt (Dubreuil, 1908), Hybrid Tea—This should be in every garden. A semi-climber, good for a red pillar. The flowers are a brilliant scarlet-ermson that does not fade into an unpleasant shade, but becomes quite a good velvety purple. The flowers are quite large, and although only of few petals, one might call them semi-double, yet the younger blooms have quite a good point and are of excellent shape. It is free flowering, and the flowers are produced in trusses

THE ROSE GARDEN.

NOTES ON THE NEWER ROSES.

SOME DECORATIVE VARIETIES.

(Continued from page 641.)

Excelsa (H. M. Walsh, 1910), wichuriana.—A double-flowered Hiawatha, rather deeper and better coloured than Crimson Rambler, with the advantage of being late flowering.

Flower of Fairfield (Schultheis, 1908), a perpetual (so called) flowering Crimson Rambler.—It undoubtedly flowers on the wood of this year's growth, but is terribly subject to mildew, and I have discarded my plants of it this autumn.

Miss Hellyett (Lacque et Fils, 1909), wichuriana.—To my mind this is one of the best of recent introductions in this rapidly-growing class. It is a very vigorous grower, as rampant as American Pillar, and the flowers are of large size for this class, in the bud stage not unlike Lady Waterlow,

A WATERFALL IN THE ROCK GARDEN AT WARLER PRIORY.

of three to five on the laterals from last year's wood in the early part of the season, and again in the autumn on the wood of this year's growth. Not quite free from mildew, perhaps, but only slightly attacked. With me it has been one of the most satisfactory of the new climbers, and I can thoroughly recommend it to the trade (who appear to have overlooked it) and amateur alike.

Seagull (M. Prichard, 1909).—A very pretty little single, flowers the size of a shilling, colour pure white with yellow stamens, produced in very large clusters containing fifty flowers or more. It is a very rampant grower, having made several shoots more than twenty feet long with me this season. The flowers are not unlike that old-fashioned Rose *The Garland*, but are a better and purer white. I should say it is mildew-proof. It only flowers once, but the buds are so numerous that it is in flower for quite two months.

Sheilagh Wilson (Paul and Son, 1911).—A semi-climbing Hybrid Tea raised by Dr. J. Campbell Hall. I first saw it in his garden at Monaghan. It is described as a better-shaped and longer-petalled Carmine Pillar—and this is true of it—but so far with me it has not proved anything like so free flowering as that variety, and might almost be described as a shy flowerer. It certainly is more perpetual, and I had a few flowers in the autumn; but so far it does not grow with me beyond 8 feet. Perhaps when

it is better established it will improve both in the quantity of flowers and in growth.

Shower of Gold (Paul and Son, 1910), wichuriana.—This is quite a good Rose, but I am told that

Klondyke, Messrs. Paul's latest introduction, is even better. They both have most beautiful foliage, and the Rose under notice is certainly one of the best yellows, not particularly strong growing, but making, with me, an excellent pillar Rose. The flowers are of fair size, double, rosette-shaped, retaining their colour until almost the last, when they fade to white. The contrast with the foliage is excellent; indeed, the Rose is worth growing for the foliage alone, so beautiful is it. *Klondyke* has not yet flowered with me, but I am told the flowers are of a better shape, a deeper colour and an improvement on *Shower of Gold*.

Sodenia (Wegland, 1912), wichuriana.—I have not grown or flowered this variety, but it has been recommended to me to get, so I have a plant of it. It is a carmine pink of very deep colour, approaching a scarlet; described as having a larger truss than *Dorothy Perkins*, and lasting for a long time on the plant. A good grower that may prove an acquisition.

SOUTHAMPTON. H. L. MOYSEUX.
(To be continued.)

SOME GOOD FRAGRANT ROSES.

WHEN selecting the Roses for our gardens at this season of the year, it is of the utmost importance that varieties possessing the precious attribute of fragrance should for the most part be chosen in preference to others which have not been endowed in this special direction. I have for many years

THE COTTAGE GARDEN AND TEA-HOUSE AT WARLER PRIORY.

been an ardent cultivator, amid great difficulties, of Roses, especially Hybrid Perpetuals, Teas, Noisettes, Austrian Briars, wichurianas and Hybrid Teas, and I am strongly of opinion that a Rose destitute of fragrance is like a beautiful woman without sweetness of nature. Who that sees Frau Karl Druschki for the first time and has heard that one of its august parents is the intensely odorous *Caroline Testout* (the other being *Merveille de Lyon*) could possibly imagine, from its outward aspect, that such an absolutely peerless beauty among pure white varieties should know nothing of that subtly pervading fascination that only fragrance can confer?

There are many cultivators, like the late Dean of Rochester and the Rev. H. D'Ombrain, who would gladly prefer for the adornment of their much-loved gracious gardens such intensely odorous varieties, though of widely different complexion, as *La France*, *Caroline Testout* and *Viscountess Folkestone*, of which the last-mentioned Hybrid Tea, one of the very finest creations of the late Mr. Henry Bennett, has not yet been superseded, in my estimation.

There is at least one extremely graceful pure white Rose of pendulous tendency which has an exquisite fragrance, derived directly from *Souvenir d'un Ami*, and that is the variety called *The Queen in America*, and in this country *Souvenir de S. A. Prince*. This is a Tea that unfolds its floral treasures very late in the autumn. At the end of September I had it still flowering serenely and fragrantly. I have, therefore, no hesitation in recommending this charming Rose, which received its English name from the late Mr. Prince of Oxford, to those readers of *THE GARDEN* who desire to include in their collection of Tea Roses, however strictly limited, a truly sweet-scented, snowy white variety.

There are quite a number of eminent representatives of this attractive section, such, for example, as *Catherine Mermet*, *The Bride* (whose delicate green suffusion below the petals makes it seem among Roses what *Lilium speciosum* Kretzeri is among Oriental Lilies) and the *White Maman Cochet*, which have a highly distinctive fragrance, like that of a Nectarine or a ripe Peach. I find that, as a general rule, Roses of the closely compact *Catherine Mermet* family are arduous of culture, and especially in a shady garden such as mine, requiring a richly fertile soil and a warm, ripening season for their perfect floral evolution. There are many of the so-called Hybrid Perpetuals that have an exquisite fragrance. Those I most admire are *Captain Hayward*, *Hugh Dickson* (a very near approximation to perfection), *Florence Haswell Veitch* (a recent and notable introduction), *Lady Helen Stewart* (a lovely native of Larchfield Newtowards) and my own beautiful canonic rose namesake from Waltham Cross, which the late Mr. William Paul expressively

described as "one of the sweetest Roses in cultivation."

A refined aroma emanates in the tranquil, dewy evenings of summer from the China Roses, while supremely fascinating are the Austrian and Pezance Briars with their radiant flowers and fragrant leaves.

DAVID R. WILLIAMSON.

ROSE MISS CYNTHIA FORDE.

This is certainly one of the most promising of Hybrid Teas brought out within the last few years. It is very free flowering, and good alike for garden and for exhibition purposes. Already it has gained distinction as an exhibition Rose by the fact that the bloom illustrated on this page and shown by

SILVER MEDAL BLOOM OF ROSE MISS CYNTHIA FORDE.

the raisers (Messrs. Hugh Dickson) secured the silver medal at the last autumn show of the National Rose Society for the best Hybrid Tea in the show. As a garden variety this Rose possesses two precious gifts—it is almost, if not quite, mildew-proof, and is sweetly fragrant. It is brilliant rose pink in colour and possesses exceptional merits as a bedding variety. When introduced in 1900 it received the gold medal of the National Rose Society, and so far it has proved worthy of this high honour. It is true that the flowers are not quite so erect as one would wish, but its many other good points more than compensate this slight failing. It was one of the most admired of the Roses in our garden last summer.

THE ROCK AND WATER GARDEN.

POTENTILLA CLUSIANA.

POTENTILLA NITIDA, from the Dolomites, we all know, with its exquisite mats of silver foliage peppered thick with little blushing Dog Roses. (And if the peppering prove too sparse in our gardens, I believe that poor soil and squeezing the plant between stones may produce wonders in the way of blossom.) But its no less beautiful snow white counterpart, *P. clusiana*, seems to be almost unknown among us. It is a species of the Eastern limestones, where it replaces *P. nitida* at considerable elevations on cliffs and rocky ridges. It is only less beautiful than its rosy rival, developing into large, low masses of silver grey foliage (but not so silvery as in *P. nitida*), with abundance of great flowers of the purest white, not quite so large nor singly borne, nor sitting quite so close to the tuft, but none the less of very special beauty and brilliancy in all its forms, and, in the best, a really remarkable plant. Between the snowy petals peeps the hint of a rosy sepal, which gives an added charm. *P. nitida* and *P. clusiana*, woody-rooted, and often hanging in huge sheets from a microscopic crevice in some sheer limestone precipice, are both impossible to collect entire. Fortunately, however, the broken-off cushion can very easily be made to root as cuttings, and I see no reason to doubt that *P. clusiana* will prove to be of perfectly willing culture and a real treasure in the garden. Like *P. nitida*, it enhances its beauty and its value by showing both in late summer, when almost everything but the Campanulas is gone to seed. I never saw it before 1911, nor collected it seriously till last year; but it attracts me very greatly, and I desire to see nothing more beautiful than a great grey hill hung with its silver green masses, on which like thick-set stars stand out the milky brilliance of its blossoms.

REGINALD FARRER.

DWARF TREES FOR THE ROCK GARDEN.

EVERYONE is familiar with the charm that dwarf or slow growing conifers give to the alpine garden when judiciously placed, and, being evergreen, they give a furnished appearance to the garden even in the depth of winter. One of the drawbacks, however, which become apparent when they are grown in sheltered places, free from the tearing gusts of wind which their great relatives have to withstand in the alpine regions, is that they are apt to grow very dense and crowded, and so lose the characteristic lines which an old weather beaten

1.—AN UNTRAINED AND THE HEADY CONIFER. NOTICE HOW DENSE THE HEAD IS.

the previous supports, up to the main stem, aided by judicious thinning out, where necessary, those places where growth was superfluous, the result obtained was as illustrated in photograph No. 2.

After a week it was impossible, at a distance of 5 yards, to detect the wires. The two photographs were made at an interval of eighteen days, and I think the second one gives a better idea of a matured tree on a small scale than the former, and certainly is more decorative in appearance. From my own experience I think the greater number of dwarf conifers one sees in different alpine gardens could, with advantage, be so treated, except, perhaps, the rigidly erect growing ones. Of course, after a time—varying with the age of each subject dealt with—the wires may be removed, the branches having hardened sufficiently in the desired positions to so remain.

This method of procedure appears to open up a considerable avenue for decorative treatment, at an insignificant cost, and will, I think, lead to a more general use of these charming little trees in our rock gardens. REYNALD A. MAURY.

[There are many dwarf conifers suitable for the rock garden, but few are better adapted to the work than Junipers. Among others should be mentioned *Pinus pungens argentea pendula*, *P. p. diversifolia*, *P. orientalis pygmaea*, *P. o. nana*, *P. Ramontii*, *Pinus montana*, *P. Strobus prostrata*, *P. excelsa dimosa*, *P. e. globosa nana*, *Thuja dolabrata lotyriensis*, *T. japonica pygmaea*, *Tsuga canadensis pendula* and *Cupressus obtusa nana*.—E. C.

VIOLA FLORAIRENSIS.

A HYBRID between *V. rothomagensis* and *V. calcarata* was found six years ago in our garden here, and proved so superior to anything else that we gave it the name of *Floraire*. It is a very low and rather creeping plant, like *V. saxatilis*, but its flowers, instead of being dark purple, are pale blue, with a light blue centre, marked with fifteen or seventeen dark stripes, and with a golden eye. The flowers are large and well formed, but the main charm of the plant is its long, or, rather, its perpetual inflorescence. It flowers here the whole year through. I do not know another plant so floriferous as this one and so easy to cultivate. It sows itself everywhere when once established in a rockery.

H. CORREYON,

Floraire, near Geneva.

THE FLOWER GARDEN.

LILIES: A CAUSERIE.

SURELY there can be nothing worth saying about Lilies that is unsaid. Poets and folk-lorists, writers of gardening books and scientific botanists have, to speak figuratively, worn the poor things to death.

But to speak the open and shameful truth, the gardeners have done the same murderous deed, and, nothing ashamed, are ready to repeat the treatment to fresh victims. It is this annual slaughter of the innocents that makes me feel I have a mission to fulfil, a plea to plead (one does plead pleas, does one not?). I am as well qualified for it as the Scotchman, who on his deathbed advised his son thus: "Honesty is the best policy, Jeanie, I ken full well, for I ha'e tried both." Many a Lily have I murdered with the assistance of the Lily-poisoning soil and dry, scorching summer atmosphere of this garden, and therefore I can warn. On the other hand, some pleasant groupings of Lilies have apparently settled down and so far improved from year to year that I feel I may advise. Notice I write "apparently" and "so far." That is my epistolary method of "touching wood." So often have sudden death and total disappearance followed my boastings in print of the glories of a fine specimen of some rare plant that I must confess to an uneasy feeling of dread in writing of successes, and a superstitious hope that a carefully-expressed diffidence of future prosperity may blind the Evil eye and preserve my darling from the palate of

2.—THE SAME CONIFER AFTER THE BRANCHES HAD BEEN TRAINED AS DESCRIBED IN THE ACCOMPANYING ARTICLE. NOTE THE NATURAL CONTOUR.

tree assumes. This is probably accentuated by very little attention being given them with regard to their shape by the nurseryman.

Conifers in the mountains, where they often look so picturesque clinging to some projecting crag do not have this mop-headed appearance, but show an airy grace which, if we could secure it in our small specimens in the alpine garden, would be a great acquisition. Having made some experiments in this direction, I venture to bring them forward so that others may take advantage of any secret they may possess, and, doubtless, other growers will vastly improve upon my examples.

Photograph No. 1 shows a little conifer just received from the grower, and though it appears somewhat ill-shaped, had, in my opinion, the making of a suitable specimen for a projecting shoulder in the rock garden, if only the matured aspect could be introduced into it. It illustrates the dense cluster of growth which is more or less often met with in young, slow-growing conifers. I carefully planted it in the desired spot, and roughly staked it to prevent movement by wind. After rain had consolidated the soil about its roots, I replaced the three sticks with three pieces of thin copper wire, this standing the weather better than most other kinds, and having the very great advantage, in my case, of becoming almost invisible by tarnishing in a short time. Small bandages of leather were placed upon the stems, before putting the wires on them, to prevent chafing. Then, by gently bending down the branches into positions which were more suitable for the effect I desired, and fixing them with short pieces of copper wire either to

the slug. It is too true that hundreds of thousands of Lily bulbs reach this country annually, only to flower and die. This is, in a great measure, due to the nature and structure of their bulbs. The many scales of which they are composed are, in fact, underground leaves, in which a great amount of nutriment has been stored. They may be compared with certain succulent plants, such as the Aloes and Agaves, which produce large fleshy leaves of great size and weight, and for many years continue to store up a reserve of food in them. The Agaves at length use it all up in a mighty effort of flowering and seeding, and then perish; but Aloes, Gasterias and such plants use but little of the store when their roots are healthy and have access to food and moisture, and even form new leaves in a season as well as produce flowers. *Lilium giganteum* resembles the Agave, and after storing food for some six or more years, exhausts it all in one rapidly-growing flower-stem. *L. tenuifolium* also naturally flowers, seeds and dies; and though preventing its bearing seed may prolong its life for another season, that is all that can be done, and it seems best to gratefully accept all the seed it will give and, when ripe, to sow it—as the Irishman said, “at once, or sooner if possible.” But most Lilies follow the example of the latter type of succulent plants, and when healthy and in suitable surroundings add annually to the number of their bulb scales and the general weight of nutriment.

Thus it happens that Lily bulbs can be grown to a good size and weight, and having so much food stored in them, even after months of knocking about on journeys and in salerooms, are still alive and capable of flowering in the following season, but they are invalids, and without the treatment of a convalescent home their brave and cheerful display is at the expense of their strength, and their label becomes a mere tomb-stone.

Therefore I warn and exhort thus: If you cannot procure home-grown sound bulbs in September, but are tempted by the lower prices of imported ones, measuring as many inches round the chest as the Fat Boy of Peckham, in December, and wish to save their lives and have some hope of establishing them permanently in your garden, you must pot or box up the bulbs in a mixture of sharp sand and leaf-soil, keeping them in a cold frame or house until they are well rooted, planting them in their permanent homes in spring just before their stems appear above ground; and, most important of all, you must make up your mind to forego the first season's flowers and harden your heart to nip off all the tiny buds as soon as they can be detached without injuring the surrounding leaves. Otherwise, I fear you must be classed among the murderous horde of Lily slayers, who squander their pell on buying and killing Lilies annually to make a gay garden.

Waltham Cross.

F. A. BOWLES.

(To be continued.)

THE KITCHEN GARDEN.

SOME GOOD PEAS TO ORDER NOW.

THE summer and early autumn of the year that has just closed will long be remembered as exceptionally good in most localities for that best of all vegetables, the Green Pea. Right away from the earliest sowings until well on into September an abundance of pods were to be gathered in most gardens, but owing to the excessive wet experienced during the autumn, the seed crop in many districts did not ripen so well as we might have wished. For that reason there should be no

and is a grand Pea in every respect. It grows 18 inches high and is really a wonderful cropper. The accompanying illustration of a portion of haulm will serve to show its cropping powers, but, naturally, the pods are very much reduced in size. Pioneer is an early Pea that I like very much. It grows about three feet high, is very hardy and early, crops freely, and is of excellent flavour. Of similar height is Sutton's Ideal, a beautiful dark green podded variety that crops exceptionally well and is superb when cooked. Sutton's May Queen is also a grand first-early Pea of the taller section.

Second Earlies.—A splendid pair that come from the Reading firm, and which belong to this section, are Centenary and Prizewinner. The first named is a grand Pea for exhibition purposes and also of excellent quality, but with me it did not crop so heavily as Prizewinner. This last named I have grown regularly for seven or eight years, and no matter what the weather may be, it always does well. It is of first-class quality and a good all-round Pea. A new second early that I grew for the first time last year was International, sent out by Messrs. Carter and Co. Unfortunately, birds crippled a portion of the row, but that part which escaped their attention gave splendid results. International is undoubtedly a Pea that has come to stay. It is a little on the tall side, reaching a height of nearly six feet, but it is a good cropper and the quality leaves nothing to be desired. Daisy, as usual, gave good results. As a standard second-early Pea of short stature, Daisy will take a lot of beating. The colour of the Peas is on the pale side, but the flavour is equal to that of darker-lined sorts. Paragon Marrowfat and New Model, sent out by Messrs. Webb are first-class second-early Peas, both for exhibition and general use. The first named attains a height of about three feet, and the latter about a foot more. I know of no prettier Pea when growing than New Model.

Maincrop.—In this section, Gladstone, though an old variety, fully maintained its excellent reputation. I have grown this variety now for at least ten years and in several different kinds of soil, but it always does well, and its high quality is invariably maintained. It is a sure winner in the show tent, as the pods are well filled. It is one of the best sorts for very late crops. King George is a new variety that Messrs. Webb sent out last year, and of which I had a good row. It grows 5 feet high and is one of the best flavoured Peas that I have grown. It did not pod quite so freely as some other varieties, but this was more than compensated by its high quality and the fact that the pods were exceptionally well filled. Dreadnought is a new variety that Messrs. Carter made a great deal of stir about when they introduced it a year ago, and judging by its results last season, they were justified in doing so. A. B. G.

FIRST-EARLY PEA MAYFLOWER, A GOOD FREE-CROPPING VARIETY FOR LARGE OR SMALL GARDENS. (Much reduced.)

delay in ordering seed for sowing during the coming season; and with a view to guiding those who may be in some doubt as to which sorts to purchase, I propose to name those which did particularly well with me, or which I had ample opportunity of watching closely in other gardens.

First Earlies.—Previous to last year I had not grown Carter's Eight Weeks, but so well did it behave that it will certainly find a place in the garden again this season. It is a very dwarf and robust variety, exceptionally hardy, and one of the freest cropping early Peas that I know. Its quality, too, is excellent. Mayflower, sent out by the same firm, follows Eight Weeks very closely,

GARDENING FOR BEGINNERS.

HOW TO PROPAGATE CHRYSANTHEMUMS.

DURING the early half of January and onwards to the month of April, lovers of Chrysanthemums will be busy inserting cuttings so as to secure good batches of plants for the production of exhibition blooms, specimen plants, plants for greenhouse decoration, for the supply of cut flowers, and for outdoor borders. For every purpose, in order to be successful, the cultivator should make a good and careful beginning. He must use sound judgment in the selection of the cuttings, the pots and the compost. It is a great mistake to think that any kind of compost will do for rooting cuttings in, they retain the cutting soil around their roots throughout the whole of their growing season, and so we cannot have a compost that is too good for them.

Selecting Cuttings.—Where there is a good selection, the best only must be put in. These are taken from the sucker shoots growing from the soil in the pots, and not from the stems of the cut-back plants. Nos. 1, 1 in Fig. A show good sucker cuttings. They must be about three and a-half inches long; if not so long at a given date it is better to wait until they grow, rather than to cut off the stems below the soil. Cuttings so severed do not form roots freely. Nos. 2, 2 show stem cuttings with buds. Only in the case of rare varieties should such cuttings be used. They invariably take a long time to grow free of bud formation, which is often persistent during the spring months. No. 3 shows a cutting free of buds but much too weakly; No. 4, a strong cutting containing a bud. This kind is sometimes found among the sucker shoots. No. 5 depicts the kind of cutting that must be relied on to produce the best plants and blooms.

Compost, Pots and Boxes.—Fibrous loam, with the finest parts passed through a small-meshed sieve, sweet leaf-soil and coarse sand should form

STURDY BASAL CUTTINGS AND THOROUGHLY DRAINED POTS OR BOXES ARE ESSENTIAL IN PROPAGATING CHRYSANTHEMUMS.

the compost; loam two-thirds, leaf-soil one-third, and sand to make it all very porous and to induce healthy root-action. For exhibition plants cuttings should be rooted in small, deep pots singly. Others for decorative purposes and for the garden border must be rooted in larger pots, several cuttings in a pot, and in boxes. All vessels and crocks must be clean. No. 6 shows a cutting-pot crocked and the level of the surface soil. No. 7 depicts the same pot and the way in

which the cutting is inserted with sand on the surface and around the base of the cutting. No. 8, the section of a box duly prepared for cuttings, and No. 9 the drainage holes in the bottom of the box. If holes are not made in the boards, the latter should have spaces between them when nailed in position.

No. 1 in Fig. B shows how cuttings are inserted round the edges of large flower-pots, and No. 2 the way they are inserted singly in small pots. A greenhouse temperature, or that of a slightly warmed frame, is most suitable for the cuttings; they ought not to be subjected to a strong bottom-heat. A small frame put on the greenhouse stage, as shown at No. 3, is an ideal place in which to propagate Chrysanthemums. There is just sufficient heat in a frame so placed, and excessive damp can be expelled. In all kinds of weather such frames may be opened a little every morning. When sufficiently rooted the young plants may be transferred to another stage, as shown at No. 4. When first repotted they should be placed on shelves not far away from the roof-glass, as shown at Nos. 5, 5. The air must be admitted from one side of the roof only at one time, so as not to cause cold draughts to blow on the newly potted plants. If subjected to cold draughts, the leaves soon flag and the growth is not satisfactory. No. 6 shows a young plant sufficiently well rooted to be repotted in a larger pot, and No. 7 depicts a plant rooted in a box, at that stage when reboxing or repotting is desirable.

It is of the utmost importance in the cultivation of Chrysanthemums to make a good beginning, and this can only be accomplished by selecting sturdy basal cuttings of the type above described. Cuttings taken from the stems of cut-back plants are rarely if ever a real success, and should only be used when basal growths are scarce. The young plants must be taken to cool frames before their stems become drawn and weakened by being subjected to a too high temperature as the longer days come. C. G.

WHEN PLANTED, THE BASE OF THE CUTTING SHOULD REST FIRMLY ON THE SOIL, AND THE POTS THEN STOOD IN GENTLE HEAT.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The New Year.—In this, the first calendar of gardening operations that I have written for THE GARDEN, I would emphasise the necessity of doing all work at the right time and as well as time and circumstances will allow. It may not happen that particular plants, vegetables or fruit are in the same condition in different gardens at any given time or date, and some may not require potting or attending to generally at the time they are mentioned, but I hope that the notes will act as useful reminders, which, after all, is their main purpose. I hope to cover the whole routine of gardening as far as space permits, though I may, perhaps, be rather inclined to dwell a little on those subjects in which I take a special interest.

Flower Garden and Pleasure Grounds.

Planting.—Having had what we may term a fairly open autumn, all odd planting operations should by now have been completed, though in the case of extensive operations this may have to go on for some considerable time. It is, however, wise to push on all planting while the weather is open, as even in the South we often get three or four weeks' frost, which stops all such work for a time, and the other kinds of ground work may be carried on during spells of frost, when it is not a good policy to be handling trees or shrubs.

Bulbs.—It often happens that the planting of various kinds of bulbs has to be deferred till alterations have been carried out in the borders of pleasure grounds and wild gardens, but no time should now be lost in getting the bulbs planted. Many of the May-flowering Tulips and other late-flowering bulbs will not have been injured by keeping them out of the ground so long, but the earlier-flowering Tulips and Narcissi will naturally suffer. All odd and small bulbs, whether newly bought in or those that have been lifted from the beds or borders during the past summer, may with advantage be planted in the wild garden or on the borders of woodland paths, and under such natural conditions they often look and do well.

Plants Under Glass.

Cleaning Operations.—After the festivities of Christmas and the New Year, which, in many instances, will have proved a drain on the plant-houses, and consequently left some of them bare, the opportunity should be taken to commence cleansing operations, as these are much more easily accomplished when a house or two can be quite cleared of plants. The cooler and consequently drier houses should be started on first, as they will keep cleaner in appearance for a greater length of time than will the stove and forcing houses, and by leaving these latter till a little nearer the spring, their cleanliness is assured during the summer months.

Forcing-House.—To keep up a supply of flowering plants and cut flowers during the spring months, a batch of bulbs and other forcing plants must be taken in each week, regulating this according to the demand.

The Kitchen Garden.

Soil Preparation.—At this season there is very little in the outside garden to be done, except in the preparation of the soil for the forthcoming crops; but this will be sufficient, as, wherever possible, all the ground should either be trenched or bastard-trenched if the very best results are to be obtained. On some soils such work can be carried out at any time, but on close, sticky soils it is well to do this in dry weather only, leaving the surface as rough as possible, thus allowing it to get the greatest benefit from the frost.

Fruits Under Glass.

Pot Vines that may have been started during December will be rapidly swelling their buds, and though a fair amount of humidity and heat should be kept up during the day, the night temperature must not be too high, nor should there be an excessive amount of moisture at night, particularly during severe frost, or the young foliage may be injured by the drip from condensation.

Early Planted-Out Vines, such as *Hamburgh* and *Sweetwater*, may now be shut up, maintaining a temperature of about 50° to 55° till the buds

begin to push nicely, when the temperature can be raised from 5° to 10°. A nice light spraying overhead once or twice on all fine days will greatly facilitate their breaking, and on dull days a moistening of the paths and borders might suffice.

Late Vineries.—Any fruit that may be hanging should be cut at once and bottled, afterwards throwing the houses quite open for a few days before proceeding to prune.

First-Early Peach-Houses.—The trees in these are now being moved along gradually, and here again a certain amount of humidity is necessary to secure a nice free pushing of fruit and growth buds. Very light sprayings at this season are all that is necessary, varying the night temperature a little according to outside conditions.

Strawberries.—To secure an early crop, a batch of these should be brought in from the frames, where they should have been for some time past. The shell of a vinery or Peach-house will prove a suitable position for them, the temperature of the freshly-shut-up houses being about right for them till the young foliage begins to push, when the temperature may be considerably increased.

The Hardy Fruit Garden.

Planting.—Any filling up in the hardy fruit garden that has not been done should be finished off at once. In cold, heavy soil too deep planting should be avoided, as it tends to unfruitfulness, especially with Pears; but in lighter soils a little mistake of this sort is not quite so noticeable. In all cases a careful spreading out of the roots and good firm planting are imperative, the latter tending to check the rampant growth which often follows the planting of young fruit trees.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Sweet Peas.—We are now being inundated with catalogues in general and Sweet Pea catalogues in particular, and the work of selecting varieties for the coming season's display cannot be long delayed. The choice must be determined by the ultimate object in view. If for exhibition purposes, the selection should include several of the best up-to-date varieties; if only for general decorative purposes, while quality must be kept in view, the harmonising of colours is of prime importance.

Gladioli.—If not already attended to, the planting of Gladioli of the *Colvillei* type should be proceeded with if weather permits. They delight in a light, rich soil, and, not being quite hardy, they should be protected with some loose material, such as the stems of herbaceous plants which have been recently cut over, till all danger of severe frost is past. Plant about three inches deep.

Wallflowers.—These popular old favourites, although almost hardy, often suffer during spells of severe weather, especially when frosty winds prevail. Spruce twigs stuck into the ground thinly among the plants will help to break the currents and prevent damage, or at least reduce the extent of it.

The Rock Garden.

Snowdrops.—Where any of the rarer species of Snowdrops, such as *Galanthus cilicicus*, *G. caucasicus* and varieties of *G. Elwesii*, are planted in the lower reaches of the rockery, they will soon be showing flower, and if dirty weather is experienced it will be worth while protecting a few of them at least by placing bell-glasses or hand-lights over them to keep the blooms clean.

The Shrubbery.

Garrya elliptica.—The male plant of this ever-green shrub is highly attractive with its long catkin-like yellowish green flowers. It makes a good wall plant, but here, on the shores of the Firth of Forth, it thrives and flowers beautifully as a shrubbery plant on heavy clay. It usually comes into flower shortly after the New Year, but it has been in bloom here since the end of November.

Viburnum Tinus, better known as *Laurustinus*, is one of our most imposing winter-flowering shrubs. Although the fully-developed white

flowers are not much in evidence till mid-winter, the bright rosy tints of the unopened flowers make a brave show from autumn onwards. The variety known as *V. Tinus hirtum* is more precocious than the type, flowering persistently from the beginning of November onwards.

Pruning.—Deciduous shrubs, ornamental trees, Rambler Roses and Clematises should be pruned in the absence of frost. The pruning of Dogwoods should be delayed, as winter is their chief season of beauty. Clematises of the *Jackmanii* type may be cut hard back, but those of the *lanuginosa* type should only have the dead wood removed.

Plants Under Glass.

Chrysanthemums.—The work of propagating the decoratives and singles must now be proceeded with at once. Cuttings of these are generally more plentiful than is the case with the large-flowering section. Pots 5 inches in diameter, liberally drained and filled firmly with sandy soil, finishing off with a layer of pure sand, form a suitable medium for rooting. Dibble them in more thickly than you would the exhibition varieties.

Japanese Varieties.—A greenhouse temperature is all that is wanted, and unless the house is kept rather close, they should be struck in cases covered with sheets of glass. Remove the glass for an hour daily, and invert it when replacing in position. The cuttings should begin to root in about three weeks, when the glass should be gradually tilted up to admit air.

Tuberoses.—The bulbs of these delightfully fragrant flowers are now to hand, and a portion of them should be potted up and started forthwith. Turfy loam, with some old cow-manure, leaf-mould and sand, forms an ideal compost for them. One bulb to a 5-inch pot, or three bulbs to a 6-inch pot, will be found suitable. Plunge in a bottom-heat of about 65° and give them as light a position as possible, for they are naturally tall and inclined to "draw." The Pearl is the best variety.

Fruits Under Glass.

Strawberries.—A batch may now be brought indoors for early work. Where a house is not specially provided for them, Strawberries can be successfully forced along with other fruits, always provided they are kept near the light and a suitable temperature accorded to them. At this season a shelf in an early Peach-house is an ideal position for them.

Tomatoes.—The main crop should be sown without delay. Sow thinly and regularly in well-drained pots of rather light soil, covering the pots with panes of glass till germination takes place. Place the pots in a temperature of 55° or slightly over that.

Hardy Fruits.

Pruning.—Finish up all pruning during open weather. Small fruits may be pruned during slight frosts; it is cold work, but the improved conditions under foot compensate for this.

The Kitchen Garden.

Digging.—Turn over all vacant ground so that it may get weathered before spring. Trenching or double-digging always pays for the extra labour.

Peas.—On all but very heavy soils a sowing of Peas should now be made. *Gradus* is highly popular, but I have a preference for *William the First Improved* as a first variety; it has a good constitution and is earlier than *Gradus*, which can follow at the end of the month. Coat the seeds with red lead.

Asparagus.—Where it is intended to make a fresh plantation, the ground should now be prepared. Deep cultivation is essential to success, 2½ feet being none too deep, and I would fix 2 feet as a minimum if good results are to be expected. Where this is not available, the depth must be made up by the addition of "travelled" soil. A free root-run is also essential, so that where the natural soil is at all heavy, sand should be incorporated with it to lighten it. Being a seaside plant, the Asparagus must have a certain amount of salt afforded to it, and in gardens contiguous to the seashore this can be given in the form of seaweed. It need hardly be added that the ground should receive a liberal allowance of organic manure.

TREES AND SHRUBS.

THE BEST SHRUBS FOR LOW WALLS.

THE existence of low walls, such as those retaining terraces or surrounding some portion of the pleasure grounds, are, in my opinion, one of the most interesting features of any garden, as growing on such may usually be found some shrubs that are not generally considered hardy in the neighbourhood, but when given the protection of a low wall, and particularly when facing south or south-west, often grow luxuriantly and make good specimens. One reason in particular is responsible for this, I think, viz., that the footings of such a wall help to drain the soil. On heavy soils wet is responsible for more failures than actual frost. The locality, again, plays an important part in what can be grown, and it is surprising how in one garden a plant thrives, and in the adjoining one the greatest difficulty is experienced in keeping it alive.

Apart from all these indifferences, however, there are a host of shrubs, comprising evergreen, deciduous and flowering subjects, which may be relied upon to grow without coddling; and though many are not climbers in the true sense of the word, yet they are easily secured to a low wall with little trouble and without losing their character. Lack of space will not permit of my dealing with the various subjects at any length; I will, however, deal with them alphabetically, and those included are generally acknowledged to be hardy unless otherwise stated.

Abelia chinensis.—A good subject for a low wall; a deciduous shrub with attractive foliage and pretty pink flowers. Of neat and bushy habit, and though not quite hardy is, nevertheless, well adapted for such a position.

Actinidia chinensis.—A true climber, of fairly recent introduction, and quite hardy here at Aldenham trained to poles without the least protection. If the growths are trained horizontally, this is a fine deciduous subject. The young growths are particularly attractive, and will easily cover a large area if so desired.

Aloysia (Lippia) citriodora.—This, in favoured localities, is well worth a position on a wall, giving shelter from hard frosts during the winter. It is too well known as the Scented Verbena for any further description.

Ampelopsis.—Several varieties of this genus are indispensable for such a site, especially the smaller-leaved varieties. *A. Lowii* is one of comparatively recent introduction, and especially suited for a low wall. It is of deciduous growth, self-supporting and turns a grand colour in the autumn. *A. sempervivens* is an evergreen of dense habit with green foliage, and is particularly suited for low walls, being of slow growth compared with many of the other creepers belonging to this genus. Requires protection. *A. Veitchii* is one of the most attractive and colours well, though, of course, it is also suitable for a much larger area than a low wall.

Azara microphylla.—A Chilean shrub, but without doubt perfectly hardy in our ordinary winters, even without the protection of a wall. It is evergreen, with shining, neat foliage, and the flowers, though minute, are produced thickly in the spring, and emit a pleasing aroma easily detected when one is near. Suitable for any aspect except north.

Berberis Darwinii.—This well-known Barberry is a good evergreen subject for planting in a cold

aspect. The foliage is at all times attractive, and the beauty of the plant is further enhanced in spring when in flower.

Berberis stenophylla, though somewhat spoilt in its graceful habit when planted against a wall, may be similarly employed.

Berberis Fremontii is a charming species hailing from the Southern United States, and is generally found either on a wall or planted as a bush on the rockery. It is of comparatively slow growth, and likes a warm position. Several others of this family might be similarly tried, with, I should imagine, good effect.

Berchemia racemosa variegata.—This plant is most attractive, and might be taken for anything but a hardy climber, so delicately marked and variegated are its ovate leaves. A plant here makes good growth each season. Likes a warm position.

Bridgesia spicata syn. *Ercilla*.—A tightly-clinging evergreen climber, perfectly hardy here on an east aspect, and one that ought to be more commonly employed for clothing low walls and on houses.

Carpenteria californica.—A most beautiful evergreen with flowers resembling *Anemone japonica alba*, but needs a sheltered position in a district not too cold.

Ceanothus.—Several of these are well suited for culture on walls, but the palm must be given to *Gloire de Versailles*, a beautiful variety, very persistent in flowering.

Choisya ternata.—One that must not be forgotten. A beautiful evergreen commonly known as the Mexican Orange Flower. Further description is unnecessary.

Colletia cruciata, commonly known as the Anchor Plant on account of its curiously shaped, flattened branches, is none too hardy unless given the protection of a wall. It is of slow growth, and particularly attractive when in bloom, the white flowers being produced from old and new wood alike.

Corokea cotoneaster.—This quaint shrub might be included on a wall, and especially in cold localities, though we find it hardy here in the open. Nevertheless, it is an intensely interesting subject, and well worth a position among choice wall shrubs.

Cotoneasters.—Among these are some of the best subjects imaginable for low walls, being of close growth, and particularly ornamental when in fruit. *C. adpressa*, *C. congesta*, *C. horizontalis* and *C. microphylla* are well worth recommending.

Crataegus Pyracantha.—Fine in autumn and winter when freely berried, but if allowed to go will cover a great space in time, though not a rapid grower. It bears cutting back with impunity.

Crinodendron Hookeri.—An evergreen from Chili, and unless in very favoured spots is best placed at the foot of a wall. It has drooping scarlet flowers, freely produced on the smallest plants, and is one of our choicest shrubs.

Cydonias.—The various species and varieties of Japanese Quinces, which produce flowers of varying colours in early spring. *C. japonica*, *C. nivalis* and *C. Maulei* are all excellent.

Elaeagnus.—Among these we have several varieties with variegated evergreen foliage, which renders them most attractive at all seasons.

Escallonias include *E. philippiana* (white-flowered), *E. macrantha* (crimson) and the hybrid *E. langleyensis* (bright rose). They are some of the best and most beautiful of our evergreen climbers, or, I should say, wall shrubs.

Euonymus radicans Silver Gem is one of our most accommodating wall plants. Beautiful at all seasons, and will thrive almost anywhere.

Fabiana imbricata.—This evergreen shrub much resembles a Heath, and, though not hardy, is worth trying against a sheltered wall. Flowers highly attractive during summer.

Forsythia.—*F. suspensa* and *F. viridissima*, though generally found as bush shrubs, do remarkably well on a wall, and are wonderfully attractive in spring with their golden yellow flowers.

Garrya elliptica.—Interesting at all seasons, also when in flower and fruit. Being dioecious, both sexes should be planted.

Hedera, or Ivies.—The smaller-leaved varieties, such as *H. argentea variegata*, *H. aurea spectabilis*, *H. caenwoodiana*, *H. minima purpurea* and *H. maderiensis variegata* are all useful.

Hydrangea scandens, or *H. petiolaris*, has large, flat corymbs of white flowers, and *H. quercifolia* is another species, from the States, with attractive Oak-leaved foliage in addition.

Jasminums, both *J. nudiflorum* and *J. officinale*, the white-flowered, may be used, also *J. revoluta*.

Lardizabala biternata.—This evergreen stands well with us, and is worth a position for its large evergreen foliage.

Lonicera japonica aureo-reticulata (with variegated foliage veined with gold), *L. fragrantissima* (very early flowering, deliciously fragrant) and *L. sempervirens* (with scarlet flowers) are three to be thoroughly recommended, the latter being none too hardy, but worth a little care.

Muehlenbeckia complexa.—For a low wall this shrub might be used, though we grow it on the rock garden; but wherever it may be appropiated is a very interesting subject.

Myrtles.—One or two of these are general favourites on a sheltered position, especially *M. Ugni*.

Raphiolepis japonica.—A choice evergreen with sweetly-scented clusters of pure white flowers.

Veronica hulkeana.—A glorious plant where it does well. Likes a south or south-west wall, and must have adequate protection during the winter.

The foregoing list is by no means exhaustive, as I have purposely refrained from mentioning many because of their undoubted hardiness, and also because their freedom of growth certainly suggests that they require more space in which to display their beauty and true character.

Aldenham House Gardens, Elstree. E. BECKETT.

NURSERY NOTES.

ANNUALS AT MESSRS. CARTER'S TRIAL GROUNDS, RAYNES PARK.

FOR some time now the extensive establishment of Messrs. James Carter and Co., so long identified with High Holborn, has arrested the attention of travellers on the South Western Line, near Raynes Park Station. The huge and imposing building, with its vast labour-saving machinery (despite which, however, quite an army of workpeople find accommodation therein), has been before now exhaustively dealt with, though even to this additions are continually being made. Surrounding the building on three sides are the extensive trial grounds, of which their twenty acres or so are about equally divided between flowers

and vegetables. These grounds being as they purport to be for trial purposes, one does not meet with huge stretches of any particular kind, but rather to the proving of Messrs. Carter's numerous specialties or the testing of any stocks that may be submitted to them. Some of these last will need a certain amount of rouging before they are up to the "Holborn" standard, but with regard to the firm's specialties one cannot fail to be struck with the uniform nature of the plants in the different rows and the high class of the flowers themselves. At the time of our visit in early September some of the annuals were past their best, among them being the Sweet Peas, Stocks and the different forms of Candytuft. Of this last, however, there still remained sufficient to show the great superiority of the Hyacinth-flowered forms over the old-fashioned type. The massive heads and brilliant colour of Rose Cardinal appeal to everyone.

Nemesias were also much in evidence, Carter's large-flowered strain at once arresting attention by reason of the size of the individual blooms as well as by their richness of colouring and the fact that many of them possess quite distinct tiger-like markings. The pretty little Forget-me-not-like variety, Blue Gem, though quite a miniature compared with some of the others, is very generally admired.

Second to none in its gorgeous mass of colour was a bed of a distinct variety of the common Marigold, namely, Cocade Orange, the large double flowers, about four inches in diameter, being of a rich deep orange and borne in the greatest profusion. The distinct Meteor, lemon, striped with orange, was also in fine condition. From the ordinary kind being so common, many people have a prejudice against the Marigold as a decorative subject for the flower garden; but the sight of a batch of Cocade Orange would probably lead to an altered opinion. The French Marigolds, too, are very fine, and show a wide range in colour and in marking.

Vying with the Marigold in brightness of colouring stand out the several varieties of Eschscholtzia, to the improvement of which Messrs. Carter have of late years devoted a good deal of attention. The result of their labours are to be seen in the richly-coloured Carmine King and The Mikado, while the blush-tinted Dainty Queen is a decided break away.

Blue flowers are admired by many, and this colour is freely represented in innumerable shades, prominent among them being Delphiniums of sorts, the Nigellas, especially that charming variety Miss Jekyll; the daintily-tinted Nemophilas, the tiny Ionopsidium aculeate and the varied forms of Lobelia speciosa. While these last have for the most part flowers of some shade of blue, two striking departures therefrom are White Queen and Prima Donna, this last being the finest rich red variety that has ever come under our notice.

Nasturtiums, too, were a blaze of colour, the dwarf varieties especially. A notable feature of them is the wide range in colour that now exists, and also how true the different forms come from seed. For hot, dry soils especially the merits of these for the summer embellishment of the flower garden might be considered more than they are now. It is interesting to note that the dwarf Nasturtiums were first introduced by Messrs. Carter and Co.

The old-fashioned race of Cosmos, with its blossoms like single Dahlias, used to flower too late in the season for them to be of any great service, but there is now an earlier-flowering race of great

value. Messrs. Carter have the old and the new type planted side by side, one being full of flower while the other has not yet any blooms expanded.

Mignonette is largely grown, and in a mass the different tones of colour in the white, golden and red kinds are far more striking than when only considered in single spikes. Of these varieties White Queen, Golden Queen and Red King are very noticeable. One of the showiest beds was planted with Mallow Pink, Domino and White Lady, the former having large, rose-coloured blossoms, and the other pure white, both with a pleasing silky texture.

Verbenas are largely raised from seeds, and so thoroughly are they selected that they come remarkably true when increased in this way.

It is impossible to deal individually with the many subjects represented, but there were fine examples of Alyssum, Antirrhinum, Asters, Coreopsis, Centaurea, Chrysanthemum (annual), Clarkias, Dianthus, everlasting of sorts, Godetia, Larkspur, Lavatera, Linaria, Linum, Pansies, Petunia, Phlox Drummondii, Salpiglossis, Scabious, Viscaria, Zinnia and others.

While the foregoing include what may be regarded as the more generally-grown annuals, there are a few that arrest attention by reason of their attractiveness and the fact that they are very seldom seen. Among them are Abronia umbellata, a trailer with clusters of pretty pink blossoms; Argemone grandiflora, pure white Poppy-like flowers; Aretotis grandis, Marguerite-like, white and purple; Dimorphotheca aurantiaca, orange apricot, better than the newer hybrid kinds; Eutoca viscida, bell-shaped flowers, rich blue; Kaulfussia amelloides, bright blue; Phacelia campanularia, whose thimble-like blossoms are of a delightful shade of gentian blue; Platystemon californicus, soft yellow; and Thunbergia alata, orange, dark throat.

A FEW PERFECT ROSES.

WHEN is a Rose perfect? When it has scent, good formation, colour and size. A friend of mine wants a selection of perfect Roses. She wants to go into her garden and cut Roses she will be proud to own; Roses that will make their presence felt in any room they adorn. She will not waste energy on varieties that will not give thanks in fragrant or shapely blooms, and I think readers will be interested in the list I have given her.

Arthur R. Goodwin.—This has blooms of various size, some really large, poised on sturdy stems and thick, green, leathery foliage, showing up the coppery orange blooms, the centre radiating a deeper glow that spreads over the whole bloom. It is very sweetly scented and the plant has a spreading habit of growth.

Mme. Melanie Soupert.—This superb Rose once seen is never forgotten. It is not very full, but a large, deep-petalled bloom, yellowy cream, with a fusion of pale pink over the whole, sometimes more intense than at others, the edge of the petals taking on a faint carmine, especially when grown as a standard. Can be cut with very long stems.

Marquise de Sinety.—Recently classed with "Roses with Bad Habits" because of its poor colour. This quite puzzled me, as my blooms are always very deep golden yellow, with a Roman

ochre centre, and some of the deeper blooms give one the idea of a sun having set in the middle of the flower. I admit it is not a good shape, but if the blooms are cut young and the outer petals nicely arranged it is splendid.

Mrs. Aaron Ward.—In this we have one of those useful all-round Roses; a delightful bud opening a very deep apricot, specially free-blooming, with bronze foliage, and few have any idea how good it comes under glass until they have grown it in their own Rose-house.

Sunburst.—An orange yellow Hybrid Tea, very free-blooming; long, exquisitely-shaped blooms, with delicious scent; useful for any purpose and absolutely superb under glass.

Miss Alice de Rothschild.—A pale yellow, large, perfectly-formed, high-centred Tea, always in bloom and one of the best we have.

Alexander Hill Gray is the largest Tea, a well-formed yellow, being particularly fresh in colour during the dull weather. Ideal for any purpose.

Mrs. Foley Hobbs is one of the high-flowered type of Teas; ivory white, with a very faint pink that is hardly noticeable on the edge of the petals. One of the "great" Roses.

Lady Greenall.—A long-petalled Hybrid Tea, each petal perfectly arranged from a high centre. One of the best of the newer Roses. Colour, creamy saffron yellow.

Herzogin Maria Antoinette.—An intense real orange Tea with a crimson splash on the outer petals; medium sized, sweetly scented, growth of spreading habit, and never out of bloom all through the season.

Mrs. Fred Straker.—A long-pointed bud; colour, a blend of silvery fawn and faint orange; very charming.

Mrs. Theodore Roosevelt.—Large creamy white, shaded with rose pink. One of those solid, reliable blooms, opening well.

Souvenir de Maria de Zayas.—This has every petal artistically arranged from a high-pointed centre, very prettily formed, growing on long, stiff stems; a pleasing shade of crushed strawberry; sweetly scented.

Other varieties are Mme. Abel Chatenay, Elizabeth Barnes, Mme. Segond Weber, Mrs. Herbert Hawksworth, Mrs. Herbert Stevens, Entente Cordiale, Irish Beauty, British Queen, The Lyon Rose and Irish Elegance.

Now we come to shades of red. Hugh Dickson and J. B. Clark must both be grown as tall pillars. They are never so happy as when they are allowed to roam at will, and they give some splendid blooms, the latter without the split centre. Climbing Richmond and the famous George Dickson, with Red Letter Day, must have a place, as well as King George V., M. Jules Gravereaux, Florence Haswell Veitch and the charming Mrs. Edward Powell.

To complete our garden we must have arches, pergolas, banks and hedges of Roses, for which I suggested the following: Una will give yards of creamy white, semi-double blooms, very useful for cutting; Mrs. O. G. Orpen and Dawn, two pink singles, the latter blooming all through the season; Dorothy Perkins, White Dorothy, Dorothy Dennison, Excelsa, Jersey Beauty, Shower of Gold, Paul's Sylvia, American Pillar, Miss Hellyett (one of the largest of the wichuraianas), Carmine Pillar and Flower of Fairfield. Juliet and Beauté de Lyon, of the famous pernetiana section, complete my list.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

*The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.*

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Lily Bulbs from Japan.—As an indication of the vast quantities of Lily bulbs that are annually imported to this country from Japan, we may mention that one ship which arrived in London last week from Yokohama brought over no fewer than 4,000 cases.

Sir Frank Crisp.—Among the list of New Year Honours we were pleased to see that a baronetage had been conferred upon Sir Frank Crisp. His famous rock garden at Friar Park, Henley-on-Thames, is known to lovers of alpine plants in all parts of the world, and in our issue for October 26, 1912, we presented a coloured plate of a portion of it. Sir Frank is president of the Horticultural Club and takes an active interest in its work.

Oak-Leaved Primulas.—Quite a distinct break in the Chinese Primulas from any others in commerce are those possessing leaves almost identical with those of the Oak-leaved Geranium. In many instances the flowers, although set rather low, are beautifully double, and they are invariably produced in great profusion. A variety with clear salmon-shaded flowers is most pleasing, particularly early in the year, when even greenhouse flowers are none too plentiful.

Rambler Roses over Rustic Poles.—A few days ago we saw an effective method of growing some of the stronger-growing Rambler Roses, such as American Pillar. Some rough, slightly-branched poles about nine feet high had been firmly thrust into a circular lawn bed, wigwam fashion, and around and outside these the Roses had been planted, the growth nearly hiding the supports. The effect when the Roses are in bloom can easily be imagined, and the method has the merits of being simple and inexpensive.

Ground Plants for Fuchsias in Beds.—For bedding, some of the dwarfier Fuchsias are very well adapted, but the effect is often destroyed by the unsuitability of some of the flowers chosen as carpets or for groundwork. We have found nothing better for dark Fuchsias than plants of the old double white Pink, whose glaucous foliage in itself forms an admirable setting for the Fuchsias, and which is not reduced in value in the slightest by its flowers. For light Fuchsias the dwarfest blue Ageratum is as good as anything we can have. These plants were largely used by an experienced gardener years ago, and we have seen nothing better as yet to supersede them.

The Sea Buckthorn (Hippophae rhamnoides).—It is not generally known that this beautiful seashore shrub produces male and female flowers on different plants. Needless to say, the male flower-bearing plants do not produce berries; at the same time, it is advisable to have a male plant in the vicinity to obtain a good display of berries among those shrubs bearing female flowers. An even better

method is to graft branches of the male upon the berry-producing shrubs, and thus ensure a free distribution of pollen at the time of flowering. The Sea Buckthorn is a native of our seashores, though it is equally happy in inland gardens.

Delphiniums and Slugs.—In common with many other plants, the Delphiniums are commencing to grow, owing to the unusual mildness of the season. The crowns of the plants are swelling, and although they will not be seriously damaged by frosts later on, there is considerable danger from slugs. We have seen plants partially ruined by slugs eating away the young crowns. Readers who now find the crowns quite bare, owing to their being so washed by the rains, should place some fine ashes on them to a depth of 1 inch or rather more.

Hardy Heaths in Midwinter.—Owing in a large measure to the exceptionally mild weather, hardy Heaths are flowering much earlier this winter than usual. In our gardens just now Erica mediterranea hybrida, with E. codonodes or E. lusitamica, are the most beautiful, the rose pink flowers of the former and the white ones of the latter being much appreciated. E. carnea and its white variety alba are also flowering freely; the type is the best for a bold display. Closely allied to the true Ericas is the Ling, Calluna vulgaris, and the white-flowered form of this, commonly known as white Heather, is full of flower-buds that are far enough advanced to give the bed quite a white appearance. All hardy Heaths should be planted in colonies.

Two Showy Greenhouse Plants.—An effective combination of two rather uncommon plants was noted recently in the greenhouse at Kew. The plants were the Mexican Jacobinia chrysostephana and the Brazilian Tibouchina semidecandra. The latter species was grown in bush form, the individual plants being 2 feet to 2½ feet high, and composed of five or six main branches well furnished with short branchlets, from which the large purple flowers were freely borne. Jacobinia chrysostephana was represented by bushy plants about eighteen inches high, each branch being terminated by a head of orange-coloured flowers.

"The Orchid Review."—This monthly journal of orchidology is now entering its twenty-first year. The first issue appeared in January, 1893, when it was established to supply a long-felt want among amateurs of Orchids, viz., a journal devoted to their special interests. Every branch of orchidology, including cultivation, evolution, structural peculiarities, natural distribution and the vexed question of hybrid nomenclature, has been discussed and continues to be discussed in the pages of "The Orchid Review." The importance of this extremely useful work is fully recognised and appreciated by Orchid experts, and while wishing it every success in the future, we take this opportunity of congratulating Mr. R. A. Rolfe, A.L.S., the editor, on the success he has achieved.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Camellias in the Open.—Reading Mr. S. Arnott's notes on "Camellias in the Open," page 646 of *THE GARDEN* for December 28, I thought perhaps it would be of interest to others to know that we have here a tree of *C. nobilissima* now in flower, and which has been flowering off and on for the past six weeks. It has had as many as three dozen blooms expanded at one time. It is about one and a-half miles from the sea.—J. S. HIGGINS, *Glynnivon Gardens, Carnarvon*

Plants Flowering Out of Season.—Amid the many plants now flowering out of season, the most remarkable here is, I think, the common Cowslip, which does not flower in a natural way until April. In a wood on a hill having a north aspect, flowers were picked from two plants on December 17. My Christmas Roses of the *altifolius* variety growing at the foot of a south wall were all over before Christmas Day. My first flower of *Iris stylosa* was gathered on December 20, which is not an unusually early date for that variety.—E. MOLYNEUX, *Swanmore Park*.

Two Winter-flowering Honey-suckles.—All who appreciate perfume in flowers—and who does not?—should grow the Bush Honey-suckle, *Lonicera fragrantissima*, which is now in flower in many places. Old specimens will often attain a height of from 7 feet to 8 feet, and it is a pleasant surprise, on a calm day, to enter the zone of fragrance, many yards in extent, created by such a shrub, every shoot studded with small ivory white blossoms, deliciously scented. Though by no means a showy shrub, it is far from being devoid of beauty, its shoots being freely set with small white blooms. Sprays in flower when cut and brought into the house will fill the living-rooms with delicious perfume for many a day. This Honey-suckle is classed as an evergreen, but when exposed to cutting winds and severe frost it often loses its foliage. *L. Standishii* is a very similar species, bearing small white, sweet-scented flowers; but where only one is grown, *L. fragrantissima* is preferable.—WYNDHAM FITZ-HERBERT.

Narcissus pallidus præcox.—Turning up an old copy of *THE GARDEN* dated 1907, I find a note of mine in praise of *Narcissus pallidus præcox*, and I have not altered my opinion. My first flowers of it opened under glass the last week in December, and outside it had at that time burst its spathe. No Daffodil here ever opens so early, whether protected or not, and that I suppose is its chief charm to those to whom the Daffodil appeals. It is a variable and capricious plant from several points of view. For instance, in potting it, it is futile to put more than one bulb in a pot, for the flowers open at all sorts of times, and no

two flowers seem of quite the same pattern. Then, again, it is delicate in constitution, and the bulbs here seem to disappear after a season or two; but it seeds freely and, if planted in places where the seedlings have a chance of germinating and remaining undisturbed, one gets a successional supply of this pretty little Pyrenean Narcissus without the trouble entailed by successive replantings.—F. HERBERT CHAPMAN, *Rye*.

Rhododendron dauricum at Christmas.—Very rarely has this *Rhododendron* been seen to such great advantage as during the present winter, the mild weather and almost total absence of frost during the three or four weeks immediately preceding Christmas being exactly what was wanted to allow it to open its flowers, so that throughout Christmas Week it was a mass of rosy purple flowers,

are several forms of the plant, some having deciduous leaves, and in other cases the leaves are evergreen or sub-evergreen.—D.

Greenhouse Eupatoriums.—The Eupatoriums, referred to by "H. P.," page 646, issue December 28, are extremely valuable for the conservatory and greenhouse, furnishing during the autumn and winter months, or, at least, until Christmas is well past. They are very useful to amateur cultivators, as the plants can be grown in pots in the open air, just like Chrysanthemums, during the summer months. Unstopped plants yield very fine heads of flowers; plants stopped branch out freely and form nice bushes, being serviceable in this way as well as for yielding cut blooms for vases.—B.

Lewisia Cotyledon and Howellii.—It would be of value to many if Mr. Stormonth, whose note appears on page 2, January 4 issue, would tell us how long the *Lewisia* named above have been hardy in his nursery. His is not the usual experience, even in places much further South than Cumberland. So far as regards the habitats of *L. Cotyledon*, the authority of the "Index Kewensis" supports the statement by your contributor on page 365 (December 21) that these are in California. It is, however, satisfactory to learn that the above come from Alaska also, and it is quite likely that plants from that habitat will stand our winters better than those from further South. *L. Tweedyi*, which comes from Oregon, may perhaps live for a time at Kirkbride also; but one would like to learn precisely what species have stood the winter in the open for a series of years in Mr. Stormonth's most interesting nursery, which is, by the way, in a mild district for the county in which it lies.—S. ARNOTT.

Propagating Polygonum baldschuanicum.—In your issue of December 21 last it is said of this climber that "both cuttings and layers are somewhat erratic in their behaviour." Is it meant that they are difficult to strike? I have only had one experience of it, which was as follows: Last April I took thirteen cuttings of the young growth, each taken with a heel. These I placed in a pot in sandy loam, and from them obtained a dozen strong plants, several of which made growths of over twelve feet last summer. The plan I adopt for striking cuttings is as follows: Insert the cuttings in a pot in the ordinary way. Then place the pot in a larger empty pot. This pot should be so much larger that the tops of the cuttings are beneath its rim. A sheet of glass is then placed on the top, so making a sort of propagating-case. I find the cuttings strike with remarkable freedom in this contrivance. On one occasion cuttings of double Gorse had made roots over three inches long within a week, and that in an unheated greenhouse in summer.—WALTER DE H. BIRCH, *W'atton-le-dale, Lancashire*. [Our correspondent has been successful in his efforts. Sometimes cuttings root quite easily, and at others are difficult to strike successfully.—ED.]

RHODODENDRON DAURICUM, PHOTOGRAPHED IN THE ROCK GARDEN AT KEW ON DECEMBER 26, 1912.

and certainly one of the showiest of outdoor plants. Quite recently a fine group in full flower was noted between the Palm House and Temperate House at Kew, while other well-flowered examples were seen in the rock garden. An illustration of one of these, from a photograph taken on Boxing Day, is given herewith. *R. dauricum* is a native of Dahuria, Mandshuria and Sachalin, and, coming from a cold region, a spell of mild weather in midwinter causes it to begin to open its flowers very early in this country; therefore they often fall a prey to frost before they can all expand. Nevertheless, it is a good kind to plant, for in those seasons when it does escape injury it adds a bright touch of colour to the garden at a very dull season. There

Fragrant Chrysanthemums.—From my experience the single-flowered variety Mrs. Langtry is quite the strongest in perfume, and pleasing as well. This variety was very popular two decades ago. It is especially free in flower and grows vigorously in quite a small pot.—E. M.

Two Early English Flower Books.—In reply to the Rev. J. Jacob's request for information, page 652, issue December 28, 1912, Rea styles himself a gentleman, *vide* title-page of his book, "John Rea, gent." He seems not to have owned any property; at least, he rented the tenement at Kimlet, and some land he cultivated he had on lease, and probably lived on the profits from the latter. His garden he made himself, with the assistance of labourers. It has been thought by some that in the production of the poetry which distinguishes his book, his son-in-law, the Rev. Samuel Gilbert, had a more important share than those who helped him had in garden-making. Anyhow, he had the pleasure of seeing his initials appended to one effusion. The book appears in "Horticultural Bibliography" under two titles—by that given it by Mr. Jacob, which is really a sub-title for Part I., and by that on the engraved frontispiece, "Flora, Ceres and Pomona," which is the better, as it indicates the purpose of the volume. My copy has in the second title ("Flora sen et Florum Cultura") the name of Nath. Brook as publisher; the first title and the other sub-titles that of Richard Maniot. It is bound in the same style as Evelyn's "Sylva" of 1664. The second edition, it may be added, contains fuller lists of some plants than the first.—R. P. BROTHERSTON

The Flower Garden in Winter.—In reference to the plants mentioned on page 2 of your last number, I have the following in flower in the open: Iris reticulata Krelageri, Hepaticas, Lencojum vernum (Snowflake), Chionodoxa sardensis, Rhododendron racemosum, Cheiranthus alpinus, Anemone sylvestris, Arabis alba flore pleno, Chimonanthus fragrans, Crocuses (three species), Adonis amurensis, Campanula grandis, Primula denticulata, Spiraea Thunbergii, and Pyrus japonica (four varieties). In a day or two Saxifraga apiculata, S. Elizabetha, a strong spike of Delphinium (variety King of Delphiniums), three spikes on a plant of Lupinus polyphyllus and a big bush of Kerria japonica should be in full flower. Last week I had a Raspberry cane in bloom, and I can any day cut some thick sticks of Asparagus growing in the open without any adventitious aid. Walking round a neighbour's garden to-day, I noticed, among others, a yellow Carnation in flower, also an Erigeron, Achillea tomentosa, Statice tartarica and a big group of Erica arborea. By the water's edge Caltha polypetala had half-a-dozen fully-expanded flowers, and, close by, a Water Lily had five bloom-buds on it. On a south wall Ceanothus Veitchii was a mass of bloom-buds, which should open, if the present weather lasts, in about ten days' time. My wichuraiana Roses have basal shoots on them which one would be proud to see in July. It will go hard with these if severe frosts come. Just now it is not a question of what is in flower, but what is not.—B., *Weybridge*.

FORTHCOMING EVENTS.

January 15.—North of England Horticultural Society's Meeting at Leeds. Lecture by Mr. R. Farrer on "Treasures of the Alps."
January 21.—Royal Horticultural Society's Meeting and Exhibition

GARDENING ACROSTICS.

AS announced in our issue for December 14, 1912, we are publishing a series of eight acrostics based on gardening or simple botany. Prizes of £3, £2 and £1, respectively, will be awarded to those sending in correct solutions of all the acrostics. The names of those who have correctly solved the problems will be published from week to week, and the final list of prize-winners in our issue of February 22. In all cases the Editor's decision must be final. The solution to Acrostic No. 4, which appeared last week, will be published next week, and the solution to No. 5, which is printed below, will be published in our issue dated January 25. For full rules governing the competition readers are referred to page 623 of our issue for December 14, 1912.

DOUBLE ACROSTIC No. 5.

The very latest in the latest fashion in gardening. Some of the things that might be tried in them.

1. The first letters in the surnames of two of the first men who tried to find out what was inside plants.
2. The most famous "Green"
3. A seventeenth century Virgil.
4. "Seed of the Sun"—a pretty name for a fruit whose modern name might possibly be connected with "præcox"
5. A correct ending!
6. A plant with many names. The right one here is suggested by the seeds.
7. A celebrated cultivator of, and writer about, the Auricula
8. Responsible for many *quant* plant names.

Solutions of the above must be sent so as to reach the Editor at 20, Tavistock Street, Covent Garden, London, W.C., not later than January 18. Mark the envelope "Acrostic" on the upper left-hand corner.

SOLUTION AND NOTES OF ACROSTIC No. 3.

"SOPS-IN-WINE—CARNATIONS."

One of the oldest English names of the Carnation was Sops-in-wine, from their being used to flavour wine.

promotes the growth of plants. ** So-called from the resemblance of the round flower-heads to a sea-urchin. In Greek a sea-urchin is "æchinops."

SOLVERS OF ACROSTIC No. 2.

CORRECT solutions of Acrostic No. 2, which appeared in our issue for December 28, have been sent in by the following: "Observer," M. Browne, Mrs. H. Jenner, "Traveller's Joy," "White Lady," S. W. Philpott, "Retrac," E. B. Anderson, "Arnold," William Bond, Mrs. Ferguson, W. P. Wood, "Elm, Hampton," "R. P. B.," and "Scottie." The word "Hoxton" proved a stumbling-block, the majority of the solutions sent in giving this as Hampton, Holborn or Hatton Garden.

** The names of those who have correctly solved No. 3 will be given next week.

PRIZES FOR THE BEST ROCK GARDENS.

To further stimulate the interest that is being taken in rock gardens, the Proprietors of THE GARDEN offer the following prizes for three photographs of a rock garden, or portions of a rock garden:

First prize: Five Guineas, or a Silver Cup of that value.

Second prize: Two Guineas, or Books of that value.

Third prize: One Guinea.

The competition is open only to the actual owner of the rock garden, or to his or her gardener. The object is to encourage good rock gardening, and preference will, therefore, be given to those rock gardens which show originality in design, and where the plants depicted are well grown. It should be distinctly understood that awards will be made to the best rock gardens, and not necessarily to the best photographs. The photographs need not be taken by the competitor, who must, however, in such cases have the written consent of the photographer for their reproduction in THE GARDEN. The competition is subject to the following rules:

1. Not more than three photographs of each garden may be sent in by one competitor.
2. Each photograph must have the full name and address of the competitor plainly written on the back in ink.
3. Successful competitors shall furnish written particulars of the rock garden forming the subject of their photographs.
4. Glazed and mounted P.O.P. prints must be sent.
5. All photographs must be sent to arrive at THE GARDEN Offices, 20, Tavistock Street, Strand, W.C., not later than June 1, 1913.
6. Unsuccessful photographs sent in will be returned if a sufficiently stamped and addressed envelope or wrapper is enclosed, but no responsibility will be taken for the loss or damage of photographs submitted, although every care will be taken of them.
7. The Proprietors of THE GARDEN reserve to themselves the right to reproduce any photograph sent in for competition.
8. The decision of the Editor will be final.

THE GREENHOUSE.

THE RAISING OF ORCHIDS FROM SEED.

THE raising of plants from seed is always an interesting pursuit, especially when the object is to produce a new "break" in either flowers, fruits or vegetables. There is a certain degree of delightful expectancy which only those who have had practical experience can realise, and this is more especially felt when raising Orchids from

1.—HOW TO PREPARE POTS FOR ORCHID SEEDS. ON THE LEFT IS A POT READY FOR SOWING, AND ON THE RIGHT ONE CONTAINING VERY SMALL SEEDLINGS.

seed. Although much has been accomplished with this great family, more remains to be done, particularly with some genera; but we must always have an object in view, for the days of haphazard crossing are past, and the old idea "you can never tell what you will get" is obsolete. This, however, is just by the way, and we must assume that the seed-pod is ripe and the contents ready for sowing.

The House.—The methods described in the present article apply to most, if not all, epiphytal Orchids, of which *Cattleya*, *Laelia*, *Brassavola* and *Dendrobium* may be cited as examples. Seeds of the terrestrial kinds, such as *Disa*, *Cypripedium* and *Calanthe*, are best sown around plants belonging to the same genera, selecting a specimen that will not require repotting for at least a year. A warm, moist atmosphere is essential for the successful raising of Orchids from seed, and in some establishments a small frame is arranged in the warmest corner of a house where the temperature varies from 65° to 70° Fahr. If the body of the frame is extended to the floor, it can be kept 5° or more higher than the house, while, if necessary, the surroundings can be maintained near saturation point; but this ought not to be overdone, or the canvas and soil will rot before germination takes place.

Preparing the Seed-Pots.—In the first illustration are shown two pots, one just prepared for sowing the seed, and on the right hand the seedlings are ready for pricking off in store pots, although they are rather too minute to be seen to advantage in the illustration. Each pot is filled one-half of its depth with drainage; then a ball of soil, which consists of peat, partly-decayed Oak leaves and sphagnum moss, is rolled up in a piece of cheesecloth, calico, or similar material, and wedged tightly in the pot. A thin layer of sphagnum is then placed round the side and neatly clipped off, when we get an example like that on the left-hand side of the illustration. The surface must always be at least half an inch below the top of the pot,

or the seed, which is very light, may be washed over.

Sowing the Seed.—This is best sown immediately after it is ripe, excepting, perhaps, during the winter months, when it can be stored in paper where the temperature is about 60° Fahr. till spring arrives. The pans should be well watered twenty-four hours in advance, the seed may then be sprinkled lightly and evenly over the surface and not covered in any way, while the best method of distributing the seed is with the blade of an ordinary budding-knife; but after sowing one pod the knife must be carefully wiped before starting another, or the seed may get slightly mixed and cause confusion when the seedlings flower. I might state here that accurate records ought always to be kept. Careful watering is absolutely necessary, and this can be brought about by standing the pans in tepid water and allowing it to percolate through the soil, or employing one of the numerous fine sprayers. After the seed is sown it should never be allowed to become dry, but the other extreme must also be avoided.

Pricking Off the Seedlings.—In four or five weeks germination will have taken place, providing the seed was fertile, and numerous little green globules will be seen on the surface. As they become larger they are pricked off with a pointed stick into what are known as store pots. These are 2½-inch pots, which are filled three parts of their depth with drainage, the remaining space being occupied with the usual Orchid compost cut up rather fine, and closely clipped so as to form a level and firm surface. On the left of Fig. 2 may be seen such a pot as I have described, with twenty or thirty small seedlings, and as they grow more space must be given. In the other pot are three larger seedlings, and at the next repotting each would be placed in a receptacle of similar dimensions. From the time of sowing the seed till the flowering stage is reached the plants are never permitted to become dry at the base, nor is the rooting medium allowed to get into a sour condition. A moist, buoyant atmosphere is advisable and in average temperature of 65° Fahr., while cleanliness is a most important factor, for thrip will soon destroy the tiny seedlings or cripple them to such an extent that progress is considerably retarded. Although the method of raising Orchids from seed is rather different to that adopted for most other plants, yet it really presents very few difficulties. Our aim should be to flower each plant in the shortest possible time, and to this end repot directly a larger receptacle is needed or the soil is in a bad state, keep the house and seedlings quite clean, the surroundings moist, give a gentle spray overhead occasionally during the spring and summer months, using an Abol or similar spraying syringe, and maintain an equable temperature throughout the year. If these details are observed, success is assured.

ROCK AND WATER GARDEN.

HOW TO MAKE AND PLANT A STREAMSIDE GARDEN.

TO have water, whether of pond or stream, in a garden is the greatest possible gain, for it enables the ingenious garden owner or designer not only to grow in perfection many beautiful plants, but to treat the watery places, according to their nature and capability, in various delightful ways. The kind of stream that is easiest to deal with is one which has a shallow flow over a stony bottom and that is not much below the general ground-level. Here we have, ready-made, the most desirable conditions, and it is an easy matter to plant the banks and water edges without any work of shifting or shaping ground.

If the little waterway passes through dressed flower garden, it may be tamed to take its part in the garden design in rills and pools and basins, bordered with wrought-stone kerbing and planted with such beautiful things as the Japanese Iris *laevigata* and *I. sibirica*, scarlet *Lobelia* and the fine double Arrowhead. But if it passes through the outer part of the garden, or near grounds of wilder character, the plants would be, many of them, natives—the Water Plantain with its beautiful leaves, the Flowering Rush (*Butomus*), the lovely Water Forget-me-not, the deep yellow Marsh Marigold, the bright clear yellow *Mimulus*, so long acclimatised that we class it as a native; then for foliage the common Bur-reed (*Sparganium ramosum*), Lady Fern and Dilated Shield Fern; then the double form of the wild Meadow-sweet and its foreign congeners the pale pink *Spiraea venusta*, the rosy *S. palmata* and the larger white-plumbed *S. Aruncus*, native of the banks of alpine torrents. There are other of our beautiful native water-side plants, but these will be enough for a considerable length of planting. It should be remembered that the best effects are gained by some restraint in the numbers of different kinds of plants used. In one stretch of 20 feet to 25 feet the plants are blue Forget-me-not, yellow *Mimulus* and Lady Fern only, one can see and enjoy these lovely things to the full, and far better than if there were two or three other objects of interest besides. It should also be borne in mind that the plant-pictures of wise selection and good grouping are best seen from the opposite side of the stream. If its direction is sinuous, there will be ample opportunity for carrying the path across

2.—ON THE LEFT IS A POT OF SEEDLINGS THAT HAVE BEEN PRICKED OFF, AND ON THE RIGHT ONE CONTAINING THREE LARGER SEEDLINGS.

and across, so gaining different aspects of light on flower and water. The path may cross either by stepping-stones or by some very simple bridge, something much better than the so-called rustic bridge that so commonly defaces garden waters. If the stream is not shallow and stony-bottomed, it is worth a good deal of work and trouble to make it so.

Not only is it pleasant to see the clear pebbly bottom, but it makes more movement of water, and the movement brings forth that sweet babbling, the language of the water, telling of its happy life and activity. One may learn the value of this both for sight and sound at many a bridge in country places where a road crosses a running stream or small river. On one side or other of the bridge there is generally a shallow, stony place

PLAN SHOWING SECTION OF A DEEP DITCH.

where the water is not much more than ankle-deep. However ancient the bridge may be, this shallow is the evidence of a still older ford. The ford must have been made by widening the area of the flow and by shallowing the bottom, putting down stones to hinder its being washed out. It is a useful lesson in the treatment of garden streams.

Sometimes the only stream one has to deal with is running water in the bottom of a straight, deep, narrow ditch, with nearly vertical sides. Nothing can be less inspiring to the planter than such a ditch; yet, on the other hand, nothing is more stimulating to its power of invention and determination to convert unsightliness into beauty. The ditch, as it exists, is useless except as a drain, but there is the precious running water—the one thing most wanted. In such a case it is often advisable to make an entirely new channel,

able offence in all gardening. The course of the stream may be more erratic, and a glance at the sketch will show how such planning gives opportunities for planting and enjoying a limited number of pretty things at a time, for each bend of the brook may show quite a different treatment.

The soil is taken out not only for the wider, shallower stream, but nearly down to the water-level for a width of some feet on the path-side. The spare earth is thrown up beyond the path and shaped so that it rises first gently and then a little more sharply. The rest of the excavation goes on the other side of the stream, rising easily from rather near the water's edge. In the section the shrubs on the banks are shown of the size they would be about a year after planting; eventually they would be quite as big again. The course of the stream is dug out less than one foot deep, flattish rough stones are laid at the bottom, and over them smaller stones. It, as is likely, the path is inclined to be damp, it can be made dry and solid by running small stones into its surface, or it

PLAN OF A PATHWAY AND STREAM.

can be roughly laid with flat stones in the wettest places. The path must have the character of a wild path, not that of a garden walk—nothing that suggests rolled gravel, and no straightly trimmed hedges.

GERTRUDE JEKYLL.

THE ROSE GARDEN.

NOTES ON THE NEWER ROSES.

(Continued from page 9)

THE NEWER DECORATIVE ROSES.

The advance that has been made of recent years in this section of the dwarf decorative or garden Rose is very great, and yet one feels, great though it has been, it will be greater still in the near future. Those who have seen the Roses not yet in commerce feel that that much is, at any rate, assured

In dealing with these decorative Roses I shall limit my selection to those that I have grown or know intimately enough to speak of with some degree of confidence. This at once shortens my task very considerably. Might I suggest to your readers that they would help on the cause of the Rose by naming any new Rose they may have tried and found satisfactory, and by forwarding a short description for insertion in your columns. Roses vary so much in behaviour, according to the climate, soil and attention they receive, that a good Rose in one locality may easily be unsatisfactory in another, and *vice versa*. Where I have already referred to a Rose under the exhibition varieties, I shall not include it here except by reference. Very many of our new exhibition Roses are first-rate garden Roses also.

Alice Lemon (H. G. Hill, 1912).—See notes on "Hybrid Teas for Exhibition."

Andre Gamon (Pernet-Ducher, 1910), HT.—See notes on "Hybrid Teas for Exhibition."

Arthur R. Goodwin (Pernet-Ducher, 1909).—A pernetiana Rose, and one of the best of the section, so far as we have made their acquaintance; it is named after one who was once a keen rosarian, but who now goes in for bulbs! A free-flowering, pretty, decorative Rose of good habit; colour variable, pale orange yellow, veined old gold. Mildew-proof with me and scented.

Beaute de Lyon (Pernet-Ducher, 1910).—Another of this class, but in habit of growth partaking of more of the original cross, Soleil d'Or. The colour is a bright pink shade of terra-cotta, quite unusual, but which appears again in Mme. Edmond Heriot. A Rose one would grow for its

A STREAMSIDE GARDEN THAT HAS BEEN MADE FROM A DEEP DITCH.

excavating a good width so as to gain plenty of space down at the water's edge, and to give the stream some other form than a straight one. A natural stream is seldom straight, and though in gardening in general straight lines have great value, yet there are often reasons for departing from them, especially in groundwork of the wilder sort. So with our stream and its accompanying path, the character of the environment must be considered, the general lie of the land, the nature of the places where the water enters and leaves the garden and so on. The path should swing along in one easy line, not straight, but not going out of its way to twist for no reason—an unpardon-

able offence in all gardening. The course of the stream may be more erratic, and a glance at the sketch will show how such planning gives opportunities for planting and enjoying a limited number of pretty things at a time, for each bend of the brook may show quite a different treatment. The soil is taken out not only for the wider, shallower stream, but nearly down to the water-level for a width of some feet on the path-side. The spare earth is thrown up beyond the path and shaped so that it rises first gently and then a little more sharply. The rest of the excavation goes on the other side of the stream, rising easily from rather near the water's edge. In the section the shrubs on the banks are shown of the size they would be about a year after planting; eventually they would be quite as big again. The course of the stream is dug out less than one foot deep, flattish rough stones are laid at the bottom, and over them smaller stones. It, as is likely, the path is inclined to be damp, it can be made dry and solid by running small stones into its surface, or it

extraordinary colour, just as one would include Juliet; but a bed of it would be a mistake.

Berthe Gaulis (Bernart, 1910), HT.—A useful Rose. Colour, deep China pink, occasionally quite a good shape and of some size and substance. I am giving it a further trial.

British Queen (S. McGredy and Son, 1912).—See "Exhibition Varieties."

Carine (A. Dickson and Sons, 1911), HT.—A beautiful bedding Rose, and one that has been very much admired here, so much so that it was nearly always cut first if Roses were wanted for the house. That tells its own tale; at least, I think so. It is a Hybrid Tea with a great deal of

Tea blood in it. If one might venture a guess at its parentage, I should say that G. Naboumand had had something to do with it. The colour is variable, creamy lawn, coppery salmon in the early stage, but very attractive at all times. A delightful button-hole flower in the bud stage. Excellent habit of growth, flowers being carried erect. Very sweetly perfumed; altogether a desirable Rose.

Souhampton. HERBERT E. MOLYNEUX.
(To be continued)

GARDENS OF TO-DAY.

HOPETOUN HOUSE GARDENS, LINLITHGOWSHIRE.

SITUATED in one of the favoured corners of Scotland, these extensive gardens can easily claim a place of equality with the best of their

houses and, indeed, a quite modern glass equipment.

A long span-roofed house is filled with fine sturdy plants of Begonia Gloire de Lorraine, both white and pink. As these are in great demand during the winter, some five hundred plants are cultivated. Carnations of all kinds are grown in enormous quantities. A large span-roofed house was recently converted into a Carnation-house, and that it is admirably adapted for this purpose the healthy plants amply prove. A smaller house, running at right angles to the one just mentioned, was filled with a batch of young Perpetual-flowering Carnations in front, while at the back are older plants that have been giving a constant supply of fine flowers for the last twelve months. They were still, at the time of my visit, giving plenty of fine blooms on stiff, clean stems. Still another house was filled with a fine batch

grown, and also climbing Roses of the wichurana type. One of these borders is devoted to Carnations, all the most distinct border varieties being grown in hundreds.

Snapdragons.—Another section holds hundreds of Antirrhinums, all the finest of Sutton's varieties being grown. Those who have never seen Antirrhinums massed as they are at Hopetoun can have no idea of the gorgeous effect produced by these simple flowers. I shall never forget my first visit to these gardens several years ago, when the first thing to take the eye was a border in front of the Peach-houses filled with 2,000 Antirrhinums. This sight of itself was worth a long journey. Last season they were equally fine, but hardly in such numbers, I think.

Pentstemons.—While the Antirrhinums are always fine, they must surrender pride of place at Hopetoun to the Pentstemons. Nowhere have I

THE LARGE HERBACEOUS BORDER AT HOPETOUN HOUSE, LINLITHGOWSHIRE.

kind in the United Kingdom. The grounds, lawns and shrubberies at Hopetoun, which is the seat of Lord Linlithgow, are of great extent, while the garden proper covers an area of over twenty acres. I do not know who chose the site originally, but that it must have been one well versed in such matters is evident, as no finer situation for a large garden could be found anywhere. The ground slopes gently from west to east, and much more steeply from north to south, into a winding dale, or, as we call it in Scotland, a glen. To the north side are the very extensive flower gardens, while on the south side are the kitchen and fruit gardens.

The glass structures are situated at the west side of the gardens, and are of considerable extent. They comprise long ranges of fruit-houses, large stoves, Palm-houses, Orchid-houses, Carnation-

of these free Carnations, just throwing up their first spikes, and Mr. Highgate, the head-gardener, acknowledged that he was prouder of this house than of almost anything else on the place. Many other interesting subjects could be named; but space, or, rather, the want of it, compels me to pass on to what is really the glory of Hopetoun—

The Flower and Rose Gardens.—The north side of the gardens is protected by a high brick wall, against the west end of which are built the principal vineries. Further east this wall is clothed with Pears, Peaches and Apricots. The Pears last season were remarkably fine. I do not remember ever seeing finer Marie Louise and Pitinaston Duchess. In front of these Pears are broad borders, with large Rose and Sweet Pea pillars at the back. All the best Sweet Peas are

seen these glorious autumn flowers in such perfection. I have no idea how many plants are used, but they must run into several thousands. All the very finest types are planted in separate colours, and this feature of these gardens must be seen to be appreciated. Last year I think they were finer than I have ever before seen them, and that is saying a good deal. While all were fine, special mention must be made of Crimson Gem, Daydream (raised at Hopetoun) and Mrs. J. Forbes. The last named is the largest flower I have yet seen, while the spike is long and massive. Daydream is, so far as I know, by far the finest large-flowered pink, while Crimson Gem is the most striking of all the family.

East Lothian Stocks.—The late Lord Linlithgow was very fond of East Lothian Stocks, and one long border was yearly devoted to these plants.

In 1911 a border under a wall and facing east was given to these delightful old plants, and very fine they were. Planted in rows of a colour, they were greatly admired by every visitor. On a similar border, further east, is a full collection of late perennial *Filoxes*.

The Herbaceous Border. Last summer I was just late enough to see the famous winding herbaceous border at its best. On a former occasion I was fortunate enough to catch it at the height of its glory, and can safely say it is one of the finest of its kind in existence. It is a real mixed border in the best sense of the word, and none of the so-called colour-scheme freaks. The plants thrive and flower luxuriously, and all the very finest varieties of the various kinds are represented. I will not attempt to go into the merits of the different species used, but I was greatly struck with that grand biennial, *Meconopsis Wallichii*. The photograph of the border reproduced on page 22 was taken by Mr. Francis C. Inglis, photographer to His Majesty the King at Edinburgh.

The Rose Garden is on grass, the beds being large, and filled, for the most part, with one variety to each. The soil is just light enough to produce luxuriant growth, but all the varieties flower very freely and make a grand show in their season. The beds are usually carpeted with *Viola Come-to-Stay*. It would be easy to fill double the space and not exhaust the good things to be seen at Hopetoun, but I fear the Editor will even now be thinking that I have run on quite far enough. C. BLAIR.
Preston House Gardens, Linlithgow.

TREES & SHRUBS.

CULTURAL HINTS ON NEW AND RARE PLANTS. TREES AND SHRUBS.

(Continued from page 64S, Vol. LXXVI.)

Magnolia salicifolia may be grown successfully in light, sandy soil, but it will be assisted if a little peat is placed about the roots at planting-time. A little shelter, such as is afforded by other shrubs, makes an appreciable difference to its development, but it must not be planted in close proximity to very vigorous subjects. Its glistening white flowers appear in April, and it promises to become quite as useful as the well-known *M. stellata*.

Berberis Wilsonæ.—Both by its showy yellow flowers and bright red fruits this shrub is well worth a place in the shrubbery. Its requirements are simple, for, given ordinary garden soil, it will continue to give satisfaction without any special cultural attention. Pruning is unnecessary. Propagate from seeds.

Styrax Obassia.—Although not new, this Japanese shrub or small tree is very rare. Requiring well-drained, good loamy soil, it grows fairly rapidly in the warmer parts of the country, but has a habit of suddenly going wrong when in full growth.

The large, rounded leaves and white flowers make a well-developed bush very attractive.

Coroeka Cotoneaster is a rare New Zealand shrub which is well worth a position on a wall, or even in the open ground in the warmer counties. Light loamy soil, or sandy soil containing a little peat, suit it admirably. Its contorted branches, tiny dark green leaves and star-shaped, yellow flowers make it attractive.

(To be continued.)

THE DECIDUOUS CYPRESS.
(TAXODIUM DISTICHUM.)

The Deciduous Cypress is a stately tree, possessing many interesting characteristics. As its popular

A STately TREE OF THE DECIDUOUS CYPRESS IN THE GARDENS AT ST. LEONARD'S HILL, WINDSOR.

name implies, it is deciduous, and in casting its foliage in the autumn it is, with the exception of the Larch, quite unlike the general run of conifers, to which family *Taxodium* belongs. Another peculiarity of the species, and one that has created a deal of interest, is the presence of "woody knees," about two feet above the ground, sometimes produced within a few yards of the tree when grown in swampy places. When the trees are permanently surrounded by water, it is not uncommon for them to produce very much enlarged basal trunks. But *Taxodium* is evidently a very accommodating subject, as it appears to flourish equally well on the top of a hill as it does in a semi-aquatic

condition. This came out by the accompanying illustration, showing a remarkably fine specimen growing on the summit of St. Leonard's Hill, Windsor, in the gardens of Lady Foss Barry. This tree was the pride of the late Robert Brown, who for so very many years was head-gardener at St. Leonard's Hill, and whose lamented death occurred last year.

Considerable interest has lately been displayed in the fact that cones of *Taxodium distichum* were produced in different parts of the country last autumn, and an illustration appeared in our pages for November 9, 1912, of a cone bearing shoot from the Duke of Northumberland's garden at Syon House, where the tallest trees of *Taxodium distichum* in Europe are growing.

FLOWER GARDEN.

LILIES: A CAUSERIE.

(Continued from page 12.)

"Like the Lily,
That once was mistress of the field,
and flourish'd,
I'll hang my head and perish."
—"King Henry VIII.," III., I., 151.

SO Shakespeare wrote, but though he had no garden difficulties with Lilies imported from Japan or California, he here connects the fair flower with a delicacy of constitution. Our present-day failures likewise are not confined to recently-imported bulbs. We sometimes call the whole race evil names—pernickety, peevish, ill-tempered and so forth—when they will not grow as we wish and in the spot we choose for them. Our *pardalunus* perhaps refuse to produce the blaze of orange we planned in our callous modern way of planting, dubbed colour scheming. Oriental Poppies and scarlet *Salvia* grow well just there, and yet the Panther Lilies refuse to bridge over the blank moment when the croceums have gone and the Tigers have not yet appeared. Very disobliging of them, we say, but we do not stop to realise it is our own fault in selecting too hot and sunny a position for them, sorting them out by colour like silks for embroidery, and not by their own requirements, after the manner of the older and, to my mind, better school of gardeners, who thought more of the happiness of plants than of the blending of their colours. Take Baker's revision of the Liliaceæ and a map of the world, and mark a line round the native countries of Lilies. When you see what a wide stretch from East to West this line takes, and realise how many different climates must be included, and that, with the exception of the Siberian *L. davuricum* and some Chinese and Japanese species, the majority of Lilies live in more Southern and favoured climes than our England can boast, surely pity for these exiles from happier homes should replace our abuse of their inability to

acclimatise themselves without all our possible aid and sympathy.

We often wait till the frosts have cleared our flower-beds to remodel and plant, so it is just at the wettest and coldest period of the year that the poor bulbs are put into new beds—one may almost say into damp sheets, and chills and decay follow. A bulb of loose scales like a Lily is difficult to handle without bruising, or at least misplacing, some of the scales, and anything that tends to let an undue amount of water in, to lodge near the heart, and especially near a cracked portion of scale, is a serious danger in winter.

Besides care in handling, much may be done when replanting by placing sharp sand below the bulbs and tilting them slightly to one side to prevent, as much as possible, water reaching and resting in the heart, and then covering them to a depth of 1 inch or 2 inches with sand. Then we may look our Lily honestly in the face, feeling we have done our best for it, and may reasonably

and seems really to be wilful, perversicacious and wayward. It will often grow and increase in the most generous, warm-hearted way in a somewhat neglected cottage border, yet be quite unmoved by the flattery of a special bed and utterly unresponsive to the care lavished on it in some great garden. As I had the Lilies, they fall into three classes. First, the frail, delicate beauties that refuse to take a fancy to me and my garden. I name and pass by some of them: *L. japonicum* (Kramerii), *L. rubellum*, *L. superbum*, *L. tenuifolium*, *L. speciosum*, *L. elegans*, *L. Leichtlinii*, *L. Batemanniae* and *L. longiflorum*. These flower but once here, as though one good stare at what I can offer them for a home is sufficient to provoke suicide. Secondly, those that have made friends with me. Of these faithful dog-like creatures I must sing loud praises; and, thirdly, those with a cat-like disposition, that appear to love me when they happen to get just what they want, but which I always feel are ready to sulk and walk off with tail

a whole does not suffer, some of the weaker plants should be replanted. Choose a few vigorous root-growths from the outer portions of each. Before replanting, remove the soil 1 foot deep and as wide, assuming, of course, that the same subject is to occupy the same site; but if not, there will be no occasion to remove the soil. Replace the old soil with fresh. If not convenient to bring in quite new soil to the border, take some from the surface close by, replacing it with that removed from the site, adding a fourth part of manure in a decayed state. The whole of the border should be forked over between the clumps—quite lightly, of course, near the plants, so as to avoid disturbing the roots too much. Where space exists between the plants, dig the soil over deeply. As the work proceeds, bury a quantity of half-decayed stable manure near such plants as those already mentioned, as they are voracious feeders, and unless constant stimulants are applied, the growth becomes weak, and, naturally, a poor flower crop is the result.

When the digging of the border is completed, a mulching, 2 inches thick, of a compost made up of decayed vegetable refuse, old potting soil, leaf-mould, wood-ashes and road sweepings should be given. Such a covering not only imparts new life to the plants, but serves as a mulch during the early summer months, when a period of drought is often experienced.

One great fault made in the cultivation of herbaceous plants is that of allowing each specimen to grow to an unwieldy size. It is not an uncommon sight to see Michaelmas Daisies, Pyrethrums, Chrysanthemum maximum and Helenums fully a yard across at the base, with stems half the strength they should be. Supporting the stems of such clumps as these is a difficult matter. The result is they are too often tied in close together, resembling a tightly-bound broom; the natural beauty of the plant is lost and the centre of the plant quite prevented from making a free development, whereas smaller plants can easily be kept in an upright position by the aid of one or two stakes and loose ties. Instead of retaining clumps of the larger size, it is better to reduce them to 6 inches, retaining the outer portion, filling up the space with half-rotted manure and fresh soil, which will invigorate the plant retained.

Swanmore Park. E. MOLYNEUX

A HARDY BEAR'S BREECH.

(*ACANTHUS MOLLIS*.)

This strikingly handsome plant is occasionally met with in the gardens of this country, although, speaking generally, it is a sadly-neglected subject. When grown on herbaceous borders it always attracts a good deal of attention by virtue of its tall flowering spikes and its equally attractive foliage. It is a plant of easy cultivation, and the one thing to bear in mind is that it requires plenty of room, for it is notoriously vigorous in growth. In regard to soil it is not fastidious, and, given a partially-shaded position, it makes an admirable background for other flowering plants. Propagation is usually effected by division of the roots either in the autumn or at this season, providing the weather is open.

ACANTHUS MOLLIS. AN EASILY-GROWN PLANT THAT MAY BE INCREASED BY DIVISION NOW.

expect it to look back at us with fair flowers and plenty of them. The late Mr G. F. Wilson ("Lily Wilson," as he himself has told us he was named, Canon Ellacombe having been his horticultural godfather) used to say every garden could grow three Lilies, and most of them three only. That is no doubt true, if one leaves it entirely to the garden to do the growing, for *L. Martagon*, *L. pyrenaicum*, and *L. umbellatum* or *L. croceum* would grow in any garden that was not a grove of Yew trees nor unduly disturbed by deep digging in the dog-days or hard frosts; but where knowledge and care on the part of the gardener are added, it would be better to move from a garden that would not also provide healthy clumps of *L. testaceum*, *L. tigrinum*, *L. Henryi*, *L. Hansonii* and *L. pardalinum*. *L. giganteum* also, I believe, can be made happy by anyone sufficiently in earnest about it to spend a little money and to take a good deal of trouble; but *L. candidum*, the Lily of all Lilies one most longs for, behaves so strangely

stiffly erect if they get their feet wet or their milk is not to their liking, to complete the feline metaphor, which, translated into Lily language, would be to die of stagnant moisture or the wrong manure.

E. A. BOWLES

(To be continued.)

RENOVATING HERBACEOUS BORDERS.

THERE are times when it is not convenient to replant herbaceous borders, and when this is so, renovation should take place and stimulating food be provided for the occupants. Such free-growing subjects as Michaelmas Daisies, Polygonums, Bocconias, Helianthus, Chrysanthemum maximum and herbaceous Phloxes are soil exhausting, and quickly become weak if not fed. When a border is replanted, the weakening of the centre of each clump is avoided; but where replanting the whole is not convenient, then renovation must be resorted to. To do justice to the plants, so that the border as

GARDENING FOR BEGINNERS.

PRUNING AND CLEANING GRAPE VINES.

The pruning of all Vines should now be completed with all possible haste. No hard-and-fast lines can be laid down with the pruning of

1.—A VINE ROD WITH LATERAL OR SIDE SHOOTS PRUNED BACK TO TWO BUDS TO FORM SPURS.

Vines, as some cases call for quite different treatment to others. For instance, young vigorous Vines, or even comparatively old ones provided they are strong and vigorous, may be pruned to two buds, and will crop as well as though they were pruned to five or six. Vines which need plenty of young wood to ensure a good crop of fruit are old Vines which have been subjected to early forcing for a number of years. Such Vines, naturally, become weakened through being forced out of season, and it is prudent in such cases to leave plenty of young wood so that there shall be a number of vigorous shoots from which to select the best bunches. Moreover, the extra foliage resulting from these liberal measures is a great incentive to root-action. Of course, there will be a superabundance of young growth, but this must be removed as soon as it can be determined which shoots are carrying the best bunches.

Another point which must not be lost sight of when pruning old Vines is the fact that old rods which are becoming weaker every year may be replaced by young, vigorous canes, but this contingency must be provided for some years in advance by selecting convenient shoots from as near the base of the old Vines as possible, and giving these shoots every chance to make good, stout growth. The lower spurs on the old rods must be sacrificed as these young canes develop. Eventually the old rods may be cut out, leaving the young ones in sole possession of the house.

Cropping Young Vines.—There has been a great deal written from time to time of the extraordinary crops of Grapes that have been produced by Vines which have been planted only two or

three years. I do not wish to cast any doubt on the accuracy of these statements, as I have seen young Vines carrying these heavy crops, but I would warn the inexperienced Grape-grower against such a practice. This heavy cropping of young Vines, although they may have made abnormally strong growths, is almost certain to end in failure. To build up strong Vines which are going to last through one's lifetime, or even longer, a strong foundation must be laid, and this is only possible by patience and care. However strong the growth is the first year after planting, the leaders should be cut back to 2 feet or 3 feet. Vines which have made unsatisfactory progress the first season after planting should be cut back to two or three eyes. The Vines are sure to make better growth the following year.

Newly-Planted Vines.—Young Vines which are intended for planting in the spring should be cut back to three or four buds, and the strongest growth must be selected to form the leader. Vines should be planted far enough apart to grow two, three, or even more rods from each plant. The life of Vines planted on this system is far longer and the growth far more vigorous than when they are planted on the single-rod system, as witness the famous Hampton Court and Cumberland Lodge Vines.

The Cleaning of Vines is one of the most important matters which call for attention at this time of year. Vines which are badly infested with mealy-bug need very severe methods to rid them of this pest. After the Vines are pruned, the house should be subjected to a thorough cleaning. The glass and woodwork should be first well washed with strong soft soapy water. The trellis and all ironwork where the insects are likely to be secreted ought to be painted over with paraffin. The rods should then be stripped of all loose bark, and any holes which are likely to harbour insect pests must be thoroughly cleaned out. A sheet of canvas or something similar should be laid down to catch all the loose bark, and this must be taken to the stove-hole and burned. The rods must then be thoroughly washed with a strong mixture of soft soap and sulphur, using a stiff brush so that the solution may be well worked into the bark. This operation must be repeated just before the buds burst into growth, but great care must be taken so as not to damage the buds.

A careful look-out must be kept during the early stages of the Vines' growth for any stray insects which may have escaped the winter cleaning, as they

spread with alarming rapidity. A few hours' careful searching before the Vines have made much progress will save days of weary labour when the trellis is covered with growth. I have tried cleaning Vines of mealy-bug by fumigating with cyanide, but while it killed the insects which were exposed, it failed entirely to have any effect on those which were concealed in holes or crevices. I have also seen the young, tender shoots badly affected by its use.

Lockin, c

E H

HOW TO SOW BEGONIA SEEDS.

Fine seeds of tuberous and fibrous rooted Begonias are very small; they resemble dust or fine pepper, and, of course, it would be quite wrong to cover them with a body of soil. However, the proper way to sow the seeds is a very simple one, and if carefully attended to afterwards, there need be no difficulty in raising a big stock of plants successfully.

The seedlings are best raised in pots or pans. These must be clean and dry, also the crocks placed in them for drainage. A compost of sifted loam, sweet leaf-soil and sand in equal proportions should be mixed and the pans three parts filled with it. Make the surface level and smooth, and then well water through a fine-roset watering-can. In an hour's time scatter the seeds evenly and not too thickly on the surface, and on them give a very light sprinkling of sand. Place the pans on a bed of damp moss in a warm place in the greenhouse or in a heated frame, and cover the tops with squares of glass. Both before and after the seedlings appear, any necessary water should be given by immersing the pans in a vessel of tepid water until the surface soil becomes dark with the rising moisture; then gently lift out the pans. If the tiny seedlings are thus taken care of and not directly exposed to the sun's rays, they will soon grow large enough to transplant.

SHAMROCK

2.—VINES GROWN ON WHAT IS KNOWN AS THE EXTENSION SYSTEM. FREQUENTLY EACH VINE IS KEPT TO ONE MAIN ROD, KNOWN AS THE SINGLE-ROD SYSTEM.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Care of Lawns.—A well-kept lawn is a delightful adjunct to the flower garden. At no season of the year can weeds such as Dandelion, Plantains and Daisies be removed with greater ease than the present. No opportunity should be lost in getting them removed while the weather remains moist and open.

Top-Dressing.—Where the grass is apt to be thin, a top-dressing of good rich soil or short manure, well worked in, will do a great deal of good; but too heavy a dressing is apt to kill the grass, so a small quantity should be given and well worked in, to be followed with a second dressing when the grass commences to grow, if it is thought necessary.

Moss on Lawns.—Where this has got a hold among the grass, it should be scratched out with short-toothed rakes, top-dressing afterwards as advised above, or in this case a good dressing of wood-ashes, well worked in, will, in many instances, eradicate it.

The Rock Garden.

Alterations.—During open weather any alterations or additions to the rock gardens should be pushed forward, for at any time now such work may have to be suspended for a while. During such alterations any of the smaller-growing shrubs may be replanted, also some of the larger and more hardy rock garden subjects; but as far as possible the smaller and more tender subjects should be left till the end of March or early in April, when they are less likely to be affected by the frost after removal.

Propagated Plants (whether from seeds or cuttings) that are being wintered in frames should be kept as hardy and dry as possible during the winter months, as with much moisture various subjects are apt to damp off.

Plants Under Glass.

Begonia Gloire de Lorraine.—With care and attention this splendid winter-flowering plant will keep our greenhouses and conservatories gay for two or three months longer; but, as the plants are now well in bloom, the structure in which they are kept must be quite dry, with a temperature of about 50° at night.

Cinerarias, Primulas and Cyclamen are all developing their flower-buds, and should be assisted with a little manure-water as often as they become dry. The former, also, should have more space given them as they develop their heads of bloom.

Perpetual-Flowering Carnations.—Nice short-growing shoots make the best cuttings if taken direct from the hard stems. Insert either in pots, pans or shallow beds in a compost of sand, old crocks or brick dust and a little fine loam; they will soon strike in a temperature of about 50°. If a little bottom-heat is at hand, so much the better, but this is not absolutely necessary.

The Rose Garden.

Pot Roses.—The earliest batch that may have been removed under cover a week or two ago should be pruned at once preparatory to starting, and, wherever possible, the main batch should be placed under cover. Quite a cool house is the best. Here they should be allowed to get a little dry before proceeding to prune them.

Tea Roses planted out under glass, having had their season of rest, may be thinned out somewhat, removing all weakly growth and pruning the other wood back according to the system adopted and the space at hand for extension.

The Kitchen Garden.

Hot-Beds.—The matter of hot-beds must not be forgotten for the forcing of early crops of vegetables, and hard weather is often a very suitable time for preparing and mixing manure and leaves for this purpose. It is almost unnecessary to say that very wet material does not heat as well as that which is fairly dry, so the manure, leaves, &c., should, if possible, be kept under cover and turned a time or two before it is made up.

Salad Plants in frames must be gone over regularly, scratching over the surface of the soil and picking off any decaying leaves. Give as much air as is consistent with the state of the weather.

Endive should be tied up and covered over to ensure nicely-blanched plants, and Cnicory and Dandelion placed in the Mushroom-house or other forcing place in quantities sufficient to keep up a regular supply. Also Mustard and Cress should be sown weekly and placed in one of the fruit-houses that have been started. Here it will come along nicely. Cauliflower, Cabbage, Onions and Lettuce should now be sown in boxes and placed in gentle heat.

Fruits Under Glass.

Melons.—A sowing should be made at once for early crops, and if a variety such as Blenheim Orange or Hero of Lockinge is selected, the fruits will be found to ripen slightly in advance of those of some of the heavier-fruited varieties.

Cucumbers also should be sown to succeed those that are fruiting during the winter. If both the above are sown in 3-inch pots in fairly moist soil and plunged in the propagating-frame with a bottom-heat of about 70° to 75°, no water should be needed till germination has taken place.

Tomatoes.—These also should be sown in pans and placed in a warm house. Thin sowing is essential, as the plants draw very quickly during the early months of the year if the seed is sown too thickly. Sunrise and Ideal are two varieties that are excellent in every way.

Rhubarb.—Batches of this most excellent fruit or vegetable, whichever it is termed, should be placed in the forcing-house or in a frame on a hot-bed at regular intervals, according to requirements, as it will be found very useful as Apples and Pears get scarce.

The Hardy Fruit Garden.

Pruning.—The work of pruning the Apples and Pears should be started at once if not already commenced, and my plan is to start on the walls first, and this before the ground has been prepared for the vegetable crops. This is distinctly advantageous, as it saves treading about on the ground that has been worked. The work of pruning is carried out on various systems; but, judging by the trees one sees in many gardens, the methods adopted do not always fall in with one's own ideas. All trees trained on walls or espaliers should be kept as short in the spurs as possible, so as to admit a maximum amount of light to all parts of the trees.

THOMAS SIEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

The Seed Order.—The following are a few things worth including in the seed order: Asters of the Ostrich Feather and smensis types in variety, *Alyssum minimum*, *Anchusa italica* Dropmore variety and Opal, *Antirrhinum* in variety, Long-spurred Aquilegia, *Cheiranthus Allouin*, *Clarkia elegans* in variety (especially Firefly and Double Salmon), *Dimorphotheca aurantiaca* and its hybrids, *Dianthus Heddewigi* (especially Salmon Queen), *Galia coronopifolia*, *Lavatera rosea splendens*, *Leptosyne maritima*, *Myosotis Royal Blue*, *Nemesia Sutton* and N. Hybrid Blue Gray, Sweet William Pink Beauty, Swan River Daisy and *Thalictrum dipterocarpum*.

Rhododendron arboreum.—This precocious species and its varieties are showing colour earlier than usual. If sharp frosts occur, they should be protected by a mat, as for lack of this small attention a season's effort is often rendered abortive.

The Wild Garden.

Formation.—Those who can afford the room—if they do not already own one—will derive great pleasure from a wild garden. In forming one all conventionalities may be dispensed with, and one can here safely follow their "own sweet will." Try to avoid incongruities, of course, and imitate Nature; the less formal the better. Those who have the advantage of a more or less undulating surface are happily circumstanced.

The Best Plants.—Of material for furnishing there is abundance. Tall subjects include Thorns, Cherries, Crabs and Amelanchiers, while shrubby subjects include Dogwoods, ornamental Brambles, Guelder Roses and Hydrangeas. Then herbaceous subjects include *Crambe cordi-*

folia, *Senecio chrysantha*, *S. tanguticus*, Willow-herbs, Teasels, Delphiniums, Michaelmas Daisies and *Boronia cordata*. A few clumps of Sweet Peas may also be included. Dwarfier subjects include St. John's Wort, *Saxifraga peltata*, *Oreocome Candollei*, Funkias, the more vigorous Saxifrages, Irises, Polyantheses, Tulips, Snowdrops, Scillas and Dog's-tooth Violets.

The Rose Garden.

Protection.—We often have our severest frosts after this; if such occur, a little Wheat straw shaken loosely over the Teas and Hybrid Teas will preserve them from being damaged. Where planting could not be done in November, the ground should be prepared for planting next month. Work in some wood-ashes with the manure, and if the soil is deficient in lime, a little should be worked in among the top spit.

The Shrubbery.

Pruning.—Any deciduous shrubs which have not been pruned should receive attention at once to prevent the loss of sap.

Protection from Rabbits.—Where the grounds are not rabbit-proof, young, succulent specimens of Crabs, Cherries, &c., should either be protected from rabbits and hares by placing a circle of wire-netting round them or have their stems anointed with bitter aloes.

Plants Under Glass.

Begonias require a long period to germinate; therefore the sooner seed is sown the better. Fill well-drained pans with loam, peat, leaf-mould and sand, finishing off firm and smooth; water with a fine-rosed can, and after two hours sow the seed, mixing it first with some sand to aid in securing equality of dispersion. Do not cover with soil, but cover the pan with a pane of glass. Never allow the soil to become dry, and if water is required, supply it by partial immersion. Place in a temperature of from 60° to 65°.

Cinerarias.—Growth will again be more active, and mild stimulants should be applied twice a week. Vary the food; say, soot-water one week and guano-water or some other fertiliser the next.

Fruits Under Glass.

Vines.—In disbudbing always retain a strong bud for preference, but uniformity of spread must always be kept in view; therefore, if only a weak bud is available to fill a previous blank, do not hesitate to retain it.

Peaches.—Where the trees are coming into flower, maintain a rather dry, buoyant atmosphere to assist in the dispersion of the pollen. The three artificial means of pollination are by a rabbit's tail, tapping the trees, and spraying with a fine spray of water. Pollination should receive attention in the forenoon.

The Hardy Fruit Garden.

Protecting Bush Fruits.—When fruit-nets are allowed to rest on the bushes, they are often much damaged in moving them off and on; this is especially the case with Gooseberries. Both, therefore, on the ground of convenience and of ultimate economy it is much better either to have permanent supports for the ordinary fruit-nets or to net all over with bird-proof wire-netting. It has sometimes been alleged that in the event of the latter method being adopted, damage would result through drip from the overhead netting. The subject was discussed at the December meeting of the Scottish Horticultural Association, when those who have had long experience of this method of protection testified that the allegation was groundless.

The Kitchen Garden.

The Seed Order.—When making up the seed order do not fail to include the following useful items: Seakale, Beet, Asparagus Kale, Sutton's Sprouting Greens and Turnip-rooted Beet for early use.

Brussels Sprouts.—Do not throw away plants which have been stripped bare; when growth commences in spring the growing tops will furnish a very nice dish before the early Cabbages turn in.

Rhubarb.—If some loose litter or leaves are thrown over a portion of the crowns, a supply will be available from the open air a fortnight before the crop comes away naturally. But as these form a comfortable harbour for mice, which often attack the crowns, a few traps should be set near, or a little Rodine provided for them. CHARLES COMFORT.
Broomfield Gardens, Davidson's Mains, Midlothian.

**HORTICULTURAL CHANGES
IN THIRTY-FOUR YEARS.**

AS a regular subscriber to THE GARDEN and one whose first article appeared as long ago as 1879, I thank the Editor for his good wishes at the commencement of a New Year, which good wishes I am sure will be heartily reciprocated by all readers of this journal. On such an occasion one may be pardoned a slight retrospect of the various changes that have taken place within the last thirty-four years and of the plants that were then quite unknown or looked upon as of minor importance, but which now occupy a prominent position.

Of those quite undreamt of may be mentioned the *Streptocarpus*s, *Gerberas*, *Kalanchoës*, many *Primulas* (especially *P. obconica* and *P. palaecoides*), Golden-flowered *Arums*, and *Cannas*, at least in the light in which they are considered to-day, namely, as among the most desirable of flowering plants.

In the case of *Roses*, too, the changes have been great, for the single-flowered varieties were then completely ignored, the Hybrid Perpetuals were unchallenged by the Hybrid Teas, and the pretty little *Polyantha* race was then unborn. *Kosa wichuraiana*, too, whose introduction has had such far-reaching results, was then still in residence in far-off Japan, and had not made its appearance in this country.

Of *Dahlias* the massive show varieties, the tancies and the pretty little *Pompons* occupied the foremost position, though the single-flowered and the *Cactus* varieties were just beginning to assert themselves.

In *Begonias* great changes have taken place, not only in the tuberous-rooted section, but also in other classes. The most prominent feature of all has been the great influence of *Begonia socotrana* in giving us a magnificent race of winter-flowering kinds.

While *Pelargoniums* are as popular as ever, some sections, namely, the tricolor, show and fancy, have almost disappeared, but the members of the Zonal section are still universally grown, and in the Ivy-leaved class great strides have been made.

In 1879 *Chrysanthemums* were truly on the upward grade, and after a few years they reached the height of popularity; but whether they still hold that position has more than once of late furnished ground for argument.

The last decade has seen the meteoric rise of Perpetual-flowering *Carnations* and *Sweet Peas*, both of which occupy a far more important position than ever; and much the same may be said of hybrid *Orchids*, whose one stumbling-block is the outrageously long and, to the average person, senseless names applied to many of them.

Other features of the last thirty-four years are the gradual disappearance of specimen stove and greenhouse plants, especially of the hard-wooded class, and the continually increasing popularity of hardy plants of all kinds, either for the rock garden, herbaceous border, or the varied purposes to which they may be applied. Hardy trees and shrubs, especially those with showy blossoms, also occupy a higher position than they ever did before.

The rise of the *Daffodil*, too, must not be passed over, and the Rev. J. Jacob would tell us that *Tulips*, thanks to the Darwins and May-flowering

varieties, are becoming increasingly popular again while in both fruit and vegetables great strides have taken place. This list might be indefinitely extended, but the Editor's blue pencil is still a power in the land, so I will now bring my few remarks to a close.
W. TRIFLOTT

**SILVER TROPHY FOR AMATEURS'
ROCK GARDENS.**

As already announced in our pages (see July 27, 1912, page 379), the Council of the Royal Horticultural Society will offer a silver trophy presented to them by Mr. Clarence Elliott of Stevenage, for an exhibit of alpine and other plants suitable for a rock garden. These are to be arranged with rockwork in a space 6 feet by 3 feet, and the competition is to take place on May 14. The trophy, to be known as the Clarence Elliott Trophy, illustrated herewith, has been designed and carried

THE CLARENCE ELLIOTT TROPHY, OFFERED TO AMATEURS FOR ROCK GARDEN PLANTS.

out by the well-known sculptor Mr. Allan G. Wyon. It is valued at 21 guineas, and is to be won outright. The object of the donor in presenting the trophy for competition among amateurs is to stimulate interest in rock gardening. The beauty of arrangement of rocks and plants, together with the suitability of the plants employed, are points for special consideration. Full details of the rules governing the competition will be found in the forthcoming *Book of Arrangements* issued by the Royal Horticultural Society, Vincent Square, Westminster, or they may be had from Mr. Clarence Elliott, Six Hills Nursery, Stevenage, Herts.

On page 19 of this issue readers will see that we are offering valuable prizes for the best rock gardens, and we hope that those who have gardens of this kind will send us photographs of them.

**ANSWERS
TO CORRESPONDENTS.**

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor endeavors to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

SWEET PEAS (E. M. T.).—We should certainly keep the *Sweet Peas*, but they will be far better outside in some position where they can be readily protected from birds, snow or frost, and in no circumstances must frost be allowed to crack the pots. As a matter of prevention we should sow again about the middle of February. Your management must have been good to secure such an excellent result from the seeds sown.

LIMING THE SOIL (H. C. B.).—On your soil, which is light and sandy, except for the purpose of killing pests, chalk in a powdered form is the best to use instead of either slaked lime or quicklime. It should be spread at the rate of half a bushel to one bushel to the square rod now, and forked in in the ordinary course of digging. Crops may be planted immediately afterwards. The cost depends largely upon the distance the stuff has to be carted from the pits, but there are probably pits in your near neighbourhood.

THE BEST KNIPHOFIA (Lis.).—For purposes of display you cannot do better than grow *K. aloides* in variety, and by embracing the typical form with *K. a. glaucescens* and *K. a. nobilis*, a rather long flowering season would be secured. The first named is about four feet high, the others range from 5 feet to 7 feet, and are superb when well established. Perhaps one of the best is John Benary, most brilliant in colour, but somewhat more expensive than the others named. All are vigorous growers and very free-flowering. We do not know of an entirely cattle-proof *Rose*, and the more prickly sorts are as liable to get eaten as the rest. Unfortunately, cattle do not wait till the spines are fully developed, but often take the shoots in the young state; hence the difficulty. As they are 4 feet distant from the fence, however, we should imagine all but the more straggling of the branches would be safe.

GROWING NEW ZEALAND FLAX FROM SEEDS (Mrs. C.).—The New Zealand Flax, *Phormium tenax*, may be raised quite well from seeds, providing they are sown after they are ripe. If you sow them at once in well-drained boxes or pans, in a compost of equal parts of peat, leaf-mould and sand, in a temperature of from 50° to 55°, they ought to germinate during early spring. Do not cover the seeds deeply; one-eighth of an inch of soil will be quite sufficient for the purpose. After sowing, water well, and cover each box or pan with a sheet of glass and a sheet of brown paper. These will help to keep the soil moist without undue applications of water. When the seedlings are large enough to handle, prick them out in boxes 2 inches apart each way, and when well established place in a cold frame. Allow them to remain there until the following spring; then transplant them into a bed of rich loamy soil of a moist nature. Plant 1 foot apart, and the following spring transfer them to permanent positions, which should be moist rather than dry. The fibre from the leaves has been experimented with for various purposes in this country, but so far the plant has not been cultivated for commercial purposes.

LILY OF THE VALLEY AND PÆONIES (Nesta).—With your shallow soil—6 inches on chalk—we cannot hold out much hope of permanent or even temporary success with the first named, and the latter we do not advise you to plant at all. There is no great difficulty in cultivating *Lily of the Valley* with an assured depth of at least 15 inches of good soil, though high excellence would only ensue with moisture next the roots. If these were not present, the best varieties would soon dwindle to the size of those seen in woodland places; hence our advice is to considerably deepen the soil by excavating the chalk and supplying good garden soil in its stead. As you only require a small bed, the preparation suggested would not be a serious item. Single crowns of the *Lilies* may be planted 6 inches asunder, and small clumps of not more than six crowns each—larger are not recommended—at 9 inches apart each way. The *Berlin* and *Victoria* are among the larger-flowered varieties, though size is very much a matter of soil and generous cultivation. The *Pæonies* would require at least 2½ feet of good soil. They root deeply and are very voracious; hence need quite rich soil also. The old double crimson European *Pæony* is an

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Office: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Winter Greens Running to Seed.—The effect of the mild weather so generally experienced until quite recently has had a remarkable effect on winter greens. At the present time we have Savoy Cabbages and Drumhead Kale almost in flower, while even the hard buttons of Brussels Sprouts have burst and are pushing out flowering shoots. So far Chou de Russie and Purple Sprouting Broccoli have not misbehaved in this way.

Old Cyclamen Plants.—Now that the Cyclamens are once more adding their quota of beauty to the conservatory, it may be interesting to raise the question of their longevity. Owing to the general practice of growing them for one season of flowering only, it may be difficult to secure reliable data on this point. We know personally of one plant that is at least twenty-five years old, and which still gives annually a good display of flowers. It is grown in a cottage window, and is a sweet-scented form of *C. persicum*. Can any of our readers beat this?

New Secretary for Shrewsbury Show.—We understand on good authority that Mr. W. G. Brazier has been appointed secretary of the Shropshire Horticultural Society, under the auspices of which the great Shrewsbury Show is held. Mr. Brazier has been connected with the firm of Messrs. Admitt and Naunton, the late secretaries, for twenty-five years, and will, therefore, be well versed in his new duties. There were nearly fifty applicants for the post. We take this opportunity of wishing the new secretary every success and the society continued prosperity.

Rose Dorothy Perkins.—This Rose is almost an evergreen. In ordinary seasons the leaves remain on in great numbers throughout the winter; but our own plants, and others we see in gardens wide apart, are almost as green now as in summer. Last autumn, no doubt owing to the dull weather of the summer, the leaves were very green, also the bark of the branches; but in the autumn of 1911 the leaves and the bark were of a bronze colour. The wood is none too ripe now, and, as there is plenty of it, cultivators would do well to thin out old branches forthwith where there is overcrowding.

A Pretty Outdoor Effect.—Quite recently a pretty outdoor effect was noted from a group of a red-stemmed *Cornus* carpeted with Winter Aconites, the contrast between the red and yellow being very marked, especially when the sun was shining. Such an effect may be easily reproduced, for both plants are cheap and easily obtained, while they thrive almost anywhere. By selecting one of the variegated-leaved *Cornuses*, such as *alba variegata* or *Spathul*, the double advantage is obtained of having a decorative winter group and one which is showy throughout the summer. In some instances the idea may be varied by using Snowdrops or *Chionodoxas* for the groundwork.

The Caucasian Scabious.—This is undoubtedly one of the finest hardy perennials in cultivation, and as it will thrive and flower freely in almost any soil or situation, it can be strongly recommended. It produces large heads of pale lilac flowers 2 inches to 4 inches across, while the stems are long, which renders it also an ideal subject for cutting purposes.

The Glastonbury Thorn.—In regard to this remarkable *Crataegus*, which is still flowering in many gardens, it is interesting to recall the legend associated with its past history. The Glastonbury Thorn is alleged to be a descendant of Joseph of Arimathea's staff, which grew when he stuck it in the ground at Glastonbury. This tree is a variety of the common May or Hawthorn, which usually flowers about New Year's Day; the date of flowering is, however, largely dependent on the season.

Sowing Early Peas.—Although it is rather early yet to sow Peas in the open garden, it may be useful to pass on a hint that was given us some years ago by the late Charles Foster. It is to cover the seeds very lightly instead of the usual 1-inch or 2-inch covering that is desirable for later sowings. Also, if the soil is mainly clay, some sand or old potting soil placed under and over the seeds will do much to prevent them deraying. To sow Peas very early deeply in wet, cold soil is to invite failure. The above hint also applies to early sowings of Sweet Peas in the outdoor garden.

Swede Turnips for the Dining-Room.—It is difficult to understand why the small, garden forms of the Swede Turnip are not more extensively grown for human consumption. Just now we are enjoying some excellent little roots that have been stored in soil in a cool shed since November, and much prefer them to the watery white Turnips that are so largely used. We believe that the Swede Turnips contain the greatest amount of nutrition. In making out the seed order, include a small packet of garden Swede Turnips, give them good soil so that growth is rapid, and then test them with the white Turnips next winter.

A Rare Shrub (*Elliottia racemosa*).—Concerning this rarity Mr. W. J. Bean, in his notes on "New and Rare Shrubs" now appearing in *Country Life*, says: "Unless, as one hopes, some unsuspected colony exists in a wild state, it seems likely that this shrub will meet the same fate as the great auk, and disappear as a living thing from the earth—to future generations only known by museum specimens." Apparently very few plants are known to exist in a wild state, and these, like cultivated ones, seem to have lost the powers of reproduction by seed. It is a native of Georgia, U.S.A., and only two plants are at present known to be alive in Europe, both at Kew. A descriptive article and illustration of this extremely rare plant, belonging to the Heath family, appeared in our issue dated September 30, 1911.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Lonicera fragrantissima in a Fifeshire Garden. This extremely useful winter-flowering Honeysuckle has given us its pretty cream-coloured flowers for the last two years in the third week of December. It remains in bloom for a long time, and on fine days gives off its delicate fragrance quite freely. Planted three years ago against a south wall and fairly well sheltered, it is now forming a nice plant. It is easily propagated from cuttings inserted in a cold frame in August, and should be in every garden where winter-flowering shrubs in the open are in demand.—J. W. E.

Rose Sarah Bernhardt.—It is rather amusing to read some of Mr. Molyneux's notes on the newer Roses. I do not consider he is justified in saying, as he does on page 9, January 4 issue, that "the trade appears to have overlooked this Rose," just because perhaps he does not find it mentioned in catalogues that he has. I know for a fact that two well-known firms have listed it ever since its introduction by Dubreuil in 1908, and I myself have exhibited it for the last four summers. I have not only grown it, but I have a salmon-coloured sport from it that was budded in 1910.—DANE-CROFT.

Rhododendron nobleanum.—Among large-leaved evergreen Rhododendrons, this is the first to flower. The blooms sometimes open in November, and frequently, during a spell of mild weather from December to February, large bushes make a nice display. The mild weather of the past month has resulted in an exceptionally brilliant display of flowers on two large groups of this variety in the Rhododendron Dell at Kew. The illustration, prepared from a photograph taken on New Year's Day, of a portion of one of the bushes will give readers some idea of its beauty. The plants form large bushes, 10 feet to 15 feet high. The flowers are brilliant rose, changing with age to a paler shade. *R. nobleanum* is a hybrid, the result of a cross between *R. arboreum* and *R. caucasicum*. It is readily propagated by grating or layering. Flowering naturally in midwinter, *R. nobleanum* is a valuable subject for the greenhouse, the blooms opening at Christmas without the extra heat necessary to force most hardy subjects into flower by that date.—A. O.

The Tulip Tree in America.—In the issue of THE GARDEN of December 28 I notice a letter on the Tulip Tree, where it is said it is called the Saddle Tree in the United States. In the Hudson River Valley, where the tree is found in numbers in the uncare-for woods, it is known as the Tulip Tree. Give it room and it will grow

evenly and straight. It bears transplanting well, and is a very rapid grower. One I have in mind grew fully 60 feet in fourteen years. It takes its name from the shape of its flower, which resembles the Tulip. It is only attacked by a scale insect, which can be checked. In an autumn of moderate rain and plentiful sunshine, the first touch of frost turns it yellow, and it soon gains its colour, which seems like solid sunshine.—F. A. S.

Fatsia japonica.—On page 635, issue December 21 of THE GARDEN, "C. T." refers to this plant as grown in the open air in the Highgate district, North London. In the South of Hampshire

plants 7 feet through and 5 feet high, with leaves touching the ground. The many burrs this season are the result of the hot weather of 1911.—G. G.

Lewisia Cotyledon and Howellii.—In answer to Mr. Arnott's note last week, page 18, I can only say that my personal experience is short. I saw these in flower in another garden two years ago for the first time, and, carried away by their distinctive beauty, purchased a lot from their native home. These, as I before stated, came to hand last November, arriving in a very bad condition through defective packing. As we had just constructed a little moraine, three of each were

planted on the very top, just where the south-west storms—turned aside by striking the front of our house—expend their force with double fury, and yet they went through the winter and faced the terrible storm of last spring, which almost killed a Yew hedge adjoining, quite smashed up and killed a glorious specimen of *Cytisus pallidus* alongside, and ruined some fine little specimen miniature conifers near them. The *Lewisias* smiled happily through it all. Other plants were put on a wall garden in ordinary stony soil, and the rest potted. All have lived and grown as heartily as any plant we know could have done. We expected that some of these much-travelled, bedraggled plants would have died; but no, they have simply gone on, both inside and outside alike, though they have not yet got up courage enough to bloom. This I look for next season. From the appearance of the roots and the experience of one season, I should say that poor, stony soil of a good depth—say, 2 feet to 3 feet at least—and a sunny, warm aspect are necessary to their successful culture. Given these, I should not fear to plant them almost anywhere. Of course, I may yet be startled by a change in their behaviour. So far I am quite satisfied, even though I have not yet had a single bloom; but I am no longer young, and so have learned to be patient. Our situation is not a good one for delicate things, though many of our friends who visit us in summer think it is. While mild as regards frost, the whole village is swept by the storms from the south-

RHODODENDRON NOBLEANUM IN FULL FLOWER IN THE DELL AT KEW. THE PHOTOGRAPH WAS TAKEN ON NEW YEAR'S DAY.

west to such an extent that standard Roses cannot, and even bush Roses can hardly, exist, while few evergreen shrubs can be kept alive in gardens of the villagers. Again, our soil is a moist, retentive one, and growth goes on until the frost comes and cuts things down. We simply cannot grow very many things I see in our own Lakeland gardens and in the gardens on the north side of the Solway, and of many others we can never emulate the glorious specimens I often see. Of course, our collection is a remarkable one, but many of the plants are only kept in stock by the expenditure of much thought and care.—I. STORMONTH, *Kirkbride, Carlisle*.

BY THE GARDEN

Abutilon vitifolium in Ireland. This shrub appears to be quite hardy here, some eighteen miles from the sea and 250 feet above sea-level. I send you a photograph of one of my plants, taken when in full bloom. We recently had 17" of frost, but it escaped unhurt.—H. D. M. BARTON, *The Bush, Antrim*. Unfortunately, the photograph, which depicted a very good plant, was not sharp enough for reproduction.—Ed.

Fabiana imbricata.—How strange it is we do not see more plants of this Heath-like subject in the garden! When we consider how freely it grows and the abundant manner in which it blossoms annually, the wonder is emphasised. Eight years ago I put a small plant in a border only two inches wide and 18 inches deep next to a brick path at the foot of a south wall, where it has grown luxuriantly and has given extremely heavy crops of its pure white blossoms yearly without exception. If short pieces of the current year's growth are broken off in a downward direction in August or September and dibbled in sandy soil in a cold frame, every piece will grow and quickly form a stocky plant. I do not say this plant will succeed in the open in any situation or soil, but, given a warm site, such as a south wall, in sandy or peaty soil, it will quickly establish itself as a favourite in May and June when in flower and without occupying much space.—E. M.

Winter-flowering Plants.—The finest flowering plant here at present is *Laurustinus*, many of the bushes of which are white with the bloom. The south side of a hedge of this plant is also covered with flowers. It does not give such a fine display every year, but the flowers, if not always so soon out as this season, seldom fail to make a fine display somewhat later. Very fine, too, is a variety of *Arbutus*, of which there are several distinct forms here, varying in foliage, flowers and fruit. The fruit is usually ripe at this time of the year, but it is still green now. Hellebores are consistent winter bloomers here, and, like other things this season, are generally late in flowering, though the niger varieties are earlier. Our earliest, of which many dozens were used last month, is a greenish yellow named *H. odorus*, lovely for table decorations, and quick to follow it is *H. atropurpureus*, also of value for the same purpose, but not quite so refined. Then the winter-flowering Honeysuckles are a great stand-by, but it is essential that strong and long shoots be encouraged, the short twigs being far inferior as decorative objects. A not infrequent late winter flowerer is *Piptanthus nepalensis*, the young shoots of which and the foliage are equally striking. The early-flowering *Prunus Davidii* and its white variety may also be mentioned, and *Rhododendron dahuricum*, which always begins to flower in January. Of berried plants, besides the *Crataegus Pyracantha* mentioned (page 639), there are a few good things in *Cotoneaster* (the small tree), *C. frigidula*, *C. Simonsii* (a very gay and easy-to-grow plant) and the less showy *C. microphylla*. *Pernettyas*, where they succeed, are also invaluable. One of the prettiest shrubs of the present season was a yellow-berried *Yew*, and it was rather extraordinary that while missel-thrushes and other frugivora fed on the common red, they abstained from the yellow. *Daphne Mezereum*, with its wealth of sweet-scented purple flowers in January, is an object of much beauty.—R. P. BROTHERSTON, *Tynningham, Prestonkirk, N.B.*

FORTHCOMING EVENT.

January 21.—Royal Horticultural Society's Meeting and Exhibition.

GARDENING ACROSTICS.

AS announced in our issue for December 14, 1912, we are publishing a series of eight acrostics based on gardening or simple botany. Prizes of £3, £2 and £1, respectively, will be awarded to those sending in correct solutions of all the acrostics. The names of those who have correctly solved the problems will be published from week to week, and the final list of prize-winners in our issue of February 15. In all cases the Editor's decision must be final. The solution to Acrostic No. 5, which appeared last week, will be published next week, and the solution to No. 6, which is printed below, will be published in our issue dated February 1. For full rules governing the competition readers are referred to page 623 of our issue for December 14, 1912.

DOUBLE ACROSTIC No. 6.

Morphologically only a leaf; now changed in shape and function.

My wrists are the top of my whole, and my limbs are my whole standing on its head.

1. A process in plants similar to digestion in animals.
2. I scintillate when I get my South African sunshine.
3. Where was Pope's celebrated villa?
4. A sink fence.
5. What is the best way of dealing with a Kirke Plum with a dense blue bloom upon it?
6. An old rival of the Tulip, which, like it, came westwards *via* Constantinople.

Solutions of the above must be sent so as to reach the Editor at 29, Tavistock Street, Covent Garden, London, W.C., not later than January 25. Mark the envelope "Acrostic" on the upper left-hand corner.

SOLUTION AND NOTES OF ACROSTIC No. 4.

"PHILIP MILLER."

Foreigners of his day gave *Philip Miller* the title of "Hortulanorum Princeps" ("Johnson's English Gardening," page 193.)

- * 1. P ALUM
- † 2. H ORTULAN I
- ‡ 3. I DLE L
- § 4. L OBI L
- ¶ 5. I NVOLUCR E
- 6. P APAVE R

* Like "Fern," this word is often loosely used. † "O Radix Jesse" was the anthem sung by the Hortulanus at certain great feasts in Monastic times. It was one of the seven "Roman or Gregorian Great O's." The first is still marked in the Church of England calendar on December 16 (page 15 in Amberst's "A History of Gardening in England," second edition). ‡ Ideal. Glenny, in his "Properties of Flowers," always pictured an ideal flower which florists were to work for. § Lobel, or, more correctly, Pöbel, was botanist to James I., and keeper of Lord Zouche's garden at Hackney. Famous for his system of classification. (Arber's "Herbals," pages 78 and 79.) ¶ In botany the green bracts surrounding a composite flower are called an involucre. • Papaver—Barley, Wheat and Poppies formed the garland of Ceres. As opium, much used medicinally.

SOLVERS OF ACROSTIC No. 3.

CORRECT solutions of Acrostic No. 3 were sent in by the following: "Leander," "Fung," "Judith" and "Penwarne." This week we are publishing

a much easier acrostic, and we wish to inform readers that in the event of no one solving all the acrostics, the prizes will be awarded to those who solve the greatest number.

* * * The names of those who have correctly solved No. 4 will be given next week.

PRIZES FOR THE BEST ROCK GARDENS.

To further stimulate the interest that is being taken in rock gardens, the Proprietors of THE GARDEN offer the following prizes for three photographs of a rock garden, or portions of a rock garden:

- First prize: Five Guineas, or a Silver Cup of that value.
- Second prize: Two Guineas, or Books of that value.
- Third prize: One Guinea.

The competition is open only to the actual owner of the rock garden, or to his or her gardener. The object is to encourage good rock gardening, and preference will, therefore, be given to those rock gardens which show originality in design, and where the plants depicted are well grown. It should be distinctly understood that awards will be made to the best rock gardens, and not necessarily to the best photographs. The photographs need not be taken by the competitor, who must, however, in such cases have the written consent of the photographer for their reproduction in THE GARDEN. For rules governing this competition see issues for January 4 and 11.

COLOURED PLATE.

PLATE 1463

SOME NEW CENTAUREAS.

DURING recent years visitors to the principal horticultural shows in various parts of the country have had an opportunity of seeing the new forms of Centaurea, some of which are shown in the accompanying coloured plate. It is to Messrs. Jarman and Co. of Chard, Somerset, that we are indebted for these charming varieties. For many years past they have been working with and improving these flowers, which, owing to their long stems and graceful poise, are admirably adapted for use in vases and epergnes when cut. In this condition they last good for a long time, which is an additional point in their favour. The colour shades found among them are very delicate indeed, and, unfortunately, owing to difficulties in reproduction, these are none too well shown in the coloured plate. The cultivation of these Centaureas, or Sweet Sultans as some delight to call them, is quite simple. They are annual plants, and consequently the seed may be sown in the open garden, where the plants are intended to grow and bloom. An open situation and well drained, rather light soil seem to suit them best. The seed should be sown thinly during April, and as soon as the seedlings appear steps should be taken to protect them from slugs, which are very fond of them. The dusting of soot or lime between, but not on, the seedlings is a good deterrent. At an early stage of their career the seedlings should be thinned to 1 foot apart, and as soon as they are tall enough to require it, support in the form of light, branching sticks, well thrust into the ground, should be afforded.

THE KITCHEN GARDEN.

FORCING SEAKALE.

To force Seakale successfully, good, strong, well-ripened crowns are indispensable, and this has been a good season for obtaining suitable crowns. The best way is to grow a supply for forcing from thongs or root-cuttings every year, getting them rooted in the winter and planted out on a well-prepared plot of ground as early as possible, so that they have a long season of uninterrupted growth.

As soon as the leaves wither and can come off easily, crowns may be potted up in 9½-inch pots, putting about seven or eight crowns in evenly and filling up with soil firmly; then place on a stage or floor in a dark room where the temperature is not less than 60° to 65°. It is well to cover over with an inverted pot. This not only increases the darkness, but keeps a moist atmosphere and wards off draughts from the opening and shutting of doors. A supply like this can be easily kept up by putting in a number equal to the demand about every ten days. I have found, after many years of experience, that a dark cellar or room underground, with a pipe or pipes running around, is the most suitable spot for forcing Seakale, also such things as Chicory and Dandelion, and likewise for starting Mustard and Cress. Mushrooms do exceedingly well on the ground floor of such structures. Of course, quicker and better results are obtained later in the season, say, this month. During November the forcing will take four or five weeks, but as each week rolls on the forcing takes less time. The Kale should be cut as soon as ready, that is when 6 inches high. Nothing is gained by leaving it a day after it is ready to cut. It should be cut off with a heel, i.e., a slice of the old crown; this keeps it together and fresh till conveyed to the kitchen for use. Another important factor is that Seakale should be cooked as soon after it is cut as possible, to bring out its best flavour and crispness. By growing in pots much work is saved, as on wet days a number of pots can be filled and stored, and a handbarrow-load conveyed to the forcing-chamber in a few minutes at any time.

W. A. Cook

POTATO WHITE CITY.

AMONG maincrop Potatoes of recent introduction the variety known as White City deservedly occupies a high position. Introduced in 1909 by Messrs. Sutton and Sons of Reading, it was not long in finding its way into many of the best gardens in the country. Although last season was by no means favourable for the cultivation of Potatoes, White City behaved splendidly, and the illustration shows a crop of 57½ lb., or just over one bushel, from 3 lb. of sets. This may not be a particularly heavy crop, but only ordinary cultivation was adopted, and nothing whatever in the way of extra manuring or layering of growths was done. Practically all the tubers were large enough for use. In quality White City leaves nothing to be desired, the tubers when cooked being white and flowery. It

THE ROSE GARDEN.

SOME OF THE NEWER DECORATIVE ROSES.

(Continued from page 22.)

Comtesse Felicie Hoyos (Souperet et Notting, 1912). This is a good Rose. Colour, variable salmon yellow, centre rosy copper. A good grower and free-flowering. Said to be a very promising variety and an improvement on that useful garden Rose *Princesse de Bulgarie*. I have only one plant of it, and should hesitate, therefore, to recommend it; but several growers mentioned it to me as likely to prove very useful.

POTATO WHITE CITY, A GOOD MAINCROP VARIETY FOR PLANTING THIS SPRING.

C. W. Cowan (Alex. Dickson and Sons, 1912), Hybrid Tea.—What little I have seen of this Rose I liked very much. The raisers call it an improvement on *Marquis Litta*. Its colour is certainly more lasting, and it produces its flowers much more freely, entitling it to be called a good garden Rose, which is more than can be said for *Marquis Litta*. Its growth is vigorous and the colour a good cherry carmine of the shade one sees in that beautiful Rose *Souvenir de Maria Zayas*. Nearly, if not quite, mildew-proof, and with a delicious perfume.

Desdemona (Paul and Son, 1911), Hybrid Tea.—A fine huge flower that opens freely, but not exactly

retained in shape. I see the raisers call it a bold flower. It is that. Colour, deep pink. Its chief merit, I think, lies in its perfume, which is marked. I should say there was some Bourbon blood in its veins.

Duchess of Sutherland (Alex. Dickson and Sons, 1912), Hybrid Tea.—There are several points about this Rose that attracted me when I saw it at Newtownards. First of all, a quite noticeable Sweet Briar perfume that is certainly unusual in a Rose of this stamp and character; then its colour, although one must call it pink, had something out of the way about it that rendered the flower very pleasing. The raisers, I see, describe it as warm rose pink, with lemon shading on a white base; but that does not quite convey the colour as I saw it. However, it would be foolish of me to attempt to correct such past-masters in the art of colour description as the compilers of Messrs. Alex. Dickson's catalogue; but the Rose struck me as being of a colour that has no name, and with that bit of useful information I must leave it. It is a tall grower; the flowers are of good size and shape, and produced on good, stiff foot-stalks. Altogether a welcome addition.

Duchess of Wellington (Alex. Dickson and Sons, 1909), Hybrid Tea.—This is one of our best bedding yellows, and at its best a beautiful Rose, entitled to be called a yellow Killarney, although, as a rule, its flowers are hardly as large as that variety. Very free-flowering, of delightful fragrance, hardy, of good habit of growth and almost mildew-proof, I can thoroughly recommend this variety.

Duchess of Westminster (Alex. Dickson and Sons, 1911), Hybrid Tea.—I referred to this variety under "Exhibition Roses," but it should also be mentioned here. Its colour, perfume and shape are all good. The petals are large, but of rather unusual shape; but there is one point I must refer to. The buds in their early stage sometimes look misshapen, and one is tempted to pick them off as not likely to produce good flowers; but they do, and seem to recover in a marvellous fashion. It is a change to have a Rose that performs better than it promises; so many promise better than they perform.

Southampton, H. E. MOYNEUX.

SOME LITTLE-KNOWN RED HYBRID TEA ROSES.

ONE would think by the demand for Liberty and Richmond that there were but very few Roses of a red or scarlet colour among the Hybrid Teas; but really, when one searches for them, there are quite a number. Of course, they do not preponderate like the cream, orange and pink varieties; but yet there are more than at first sight appears. One lovely variety is named

Gruss an Sangerhausen, a Rose raised by that eminent German raiser Dr. Müller, to whom we are indebted for Conrad J. Meyer and the lovely semi-double *Gottfried Keller*, and, I rather think, *Gruss an Teplitz* also, although Lambert introduced it. Some have found *Grüss an Sangerhausen* only a moderate grower, but with me it makes fine, vigorous shoots. Its colour is a fine scarlet, with deep red centres. The flowers are of good size, very shapely, but they droop. This

is a fault in many respects, and one not mentioned by some writers. I notice that Mr. Molyneux, in speaking of *Nita Weldon*, ignores this very bad habit in an otherwise lovely variety. Then Gruss an Sangerhausen possesses delicious fragrance—surely a quality too rare to be overlooked—and it has also very distinctive foliage.

Sarah Bernhardt, until this last summer, has been little seen. If any reader has room for one more Rose and does not possess Sarah Bernhardt, he should procure it at once and grow it as a big bush, looping up its somewhat willowy growths to a 4-foot Bamboo cane. Last summer I cut one of the most perfect blooms from this variety I have ever had the pleasure of seeing. It was in the early morning, before the sun had had time to make it burst open, and, my word, what a bloom it was! I can see it now, and will never forget it. There was that delightful point we love to see in our favourite flower, and one wished most sincerely there were a few more petals to make the bloom more durable, for it is little more than a single. I have grown it now some six years, as it was sent out by Dubreuil in the year 1906.

Friedrichsruh is a very dark blood red—really a grand colour—but the plant is a sprawling grower, so much so that its blooms often lie on the ground. Like M. Pernet-Ducher's exquisitely dark variety *Château de Clos Vougeot*, it is best seen grown as a standard, and it is a colour that would be welcome among a line of standards.

Hippolyte Bureau.—This is a Rose that is best in autumn. At that season of the year it is splendid and well worthy of a place in any garden. The colour is carmine red, shaded velvety crimson. Very sweetly scented.

Princess Bonnie is a semi-double, vivid crimson Rose of most delicious fragrance, obtained, I believe, from the now almost extinct W. F. Bennett. It is of American origin, and one that should not be allowed to drop out of our lists. When shall we have our National Rose Garden? so that many varieties could be secured from the very hard-hearted nurseryman, who finds he must delete a lot of sorts every year from his catalogue; and if Fashion does not favour a Rose, it must go.

DASIEROIT
(To be continued.)

THE FLOWER GARDEN.

A BOLD HERBACEOUS PLANT. (CRAMBE ORIENTALE.)

IN large gardens where space is not a consideration, this ornamental Kale is worthy of a good position. It is notoriously a strong-growing plant, requiring abundance of room in order that its immense leaves may be fully developed. *Crambe orientale* is one of the largest-leaved herbaceous plants in cultivation, and when seen in full bloom, carrying myriads of its creamy white flowers, it makes an imposing and showy effect. When grown in a large circular bed, as shown in the illustration,

it is, perhaps, seen to the best advantage, although it is a very useful plant for filling out any odd corner in the summer months. It should be mentioned that *C. orientale* is a near relative of the common Seakale, and it is quite as easily grown as that well-known vegetable.

SWEET PEA NOTES.

One occasionally sees it suggested, even in the statement he not made in many words, that all the most successful exhibitors of Sweet Peas now sow the seeds in cold frames in the autumn months, and that it is only the second and third raters who continue the out-of-date system of sowing in gentle heat in the spring; while the man who sows out of doors in March is regarded as nearly as extinct as the great auk. It is possible that the people who think and say such things as these find satisfaction, but they fail to convince their fellows who go about with their eyes open.

in sufficient numbers, or the space available is not extensive enough for them. Unless they are exceptionally deep for their size, they have the disadvantage of cramping the roots somewhat in the stages shortly prior to planting in the garden. In the event of boxes being chosen, this last-named disability need not arise, since those of good depth can be selected. If they run from 6 inches to 9 inches deep, they will afford abundance of space for the roots, but great care will be required to keep so large a bulk of soil quite sweet until there are plenty of roots working in it. If boxes are used, allow a distance of 4 inches from seed to seed.

Sowing.—There can be no doubt that the seedlings thrive best when the compost is made fairly firm, and it is therefore admirable to fill the pots to within three-quarters of an inch of the edge, make the soil firm, and then to press the seeds in to the necessary depth—half an inch as a rule, but the white and spotted seeds are best when just

AN ORNAMENTAL KALE. (*CRAMBE ORIENTALE*).

As a matter of fact, many thousands of seeds are sown indoors and out of doors in the spring months, and in those instances where care and attention are devoted to the plants, superb results are achieved. Between the present date and the end of the month is admirable for those with a gently-heated greenhouse or frame; but those who have only cold structures will be wiser to defer sowing until well on in February.

The Soil.—The ideal compost consists of three parts of loam and one part of refuse manure, with enough sharp sand or grit to keep it open, and it must be pleasantly moist at the time of sowing. It is advisable to surface each pot or box with a depth of about half an inch of sand.

Pots or Boxes.—As receptacles for the seeds, it is a matter of individual convenience whether pots or boxes shall be utilised. Small pots to accommodate one seed in each are much to be preferred to large pots, but they are commonly not at disposal

level with the surface. Pressing in as suggested ensures a firm base, and a little soil can readily be put over the seeds. Many growers make a rule of chipping each seed either by cutting through the skin with a knife or filig. It does no harm and undoubtedly favours more rapid progress.

Treatment.—It is of the utmost importance that the soil shall be kept equably moist, as extremes of dryness or wetness inevitably cause trouble. The light-coloured and spotted seeds should usually be in a little drier soil than the brown or black seeds. In frames, always, and commonly also in greenhouses, it is desirable to cover each pot or box with a piece of glass to exclude mice, and, as it encourages germination, it is well to use it in all instances. The best position after the seedlings show through the surface is as close to the root glass of the structure as the pot, or boxes will stand, the object, of course, being to induce the sturdiest, stockiest growth.

LILIES: A CAUSERIE.

(Continued from page 24.)

Of the faithful few I give first place to *L. giganteum*, to which its beauty and good manners entitle it. We are old friends, for I grew my first colony from a pod of seed given me by that most generous instructor of my gardening youth, the late Dr. Lowe of Wimbledon. I strongly advise any who have the bump of patience at all developed on their cranium to accept fresh seed of this Lily whenever offered. I have saved a small quantity this season, and shall be glad to send some to any reader, as long as it lasts, who will send me an addressed envelope. If sown before it is dried up it will germinate the following spring, and the seed-pan will apparently promise a crop of Onions. Next season you might think a family of *Erythroniums* had taken their place, and the next that they are *Funkias*, and from thenceforward the glossy

the smallest size offered and planting them well, so that they may remain undisturbed for two or three years before flowering; then they will be sufficiently strong to send up full-sized flower-stems, and also should have given birth to an offset or two to take their places after their inevitable demise. I have known of large bulbs being successfully transplanted the season before flowering and producing fine stems, but only when they were transferred from a neighbour's garden and treated *en prince* as to soil and waterings; but I have also known some terribly misshapen dwarfs with a flower or two at the height of two feet something and blind buds to crown the stem, all the result of a migration at the eleventh hour. As to a choice of site, shade from the rising and midday sun is requirement number one, and protection from the north-east wind in early spring number two. That means a position to the west or north-west of tall shrubs or trees, but far enough away from them to escape

I have always followed this plan and found it most successful, only adding to it by surrounding the bulbs with sharp silver sand, a refinement that is doubtless unnecessary in a sandy Surrey garden. The bulbs should be only just below the surface, but if they work their way out too much, a good mulch of leaf-soil and well-rotted cow-manure may be given as a covering. Watering with weak manure-water will help the great flower-stem to add to its stature if judiciously supplied.

The illustration on page 35 shows a specimen of *L. giganteum* which flowered here this summer after an adventurous and almost tragic youth. When it was in its sixth year and beginning to think of preparing for flowering, Fate overtook it in the shape of my disreputable tame raven. She generally lives in the tree tops and contents herself with barking at passing rooks and sundry damages to Fir cones and Beech sprays, only coming down to be fed and to roost in her house. But in spring

Crown Imperials prove an irresistible attraction to her—I suspect on account of their dreadful scent, a mingled essence of fox and Exeter Station (though many other large stations are as ill-smelling nowadays from the gas let loose from the trains). Then one season she discovered that *L. giganteum*, though it lacked the odour, was just as amusing to slash up in its succulent youth. Two or three seasons of this mising process reduced my *L. giganteum* bulbs in a most interesting though heart-breaking manner. The bulbs dwindled to the size of three year olds, and only by wiring them round in spring and by liberal feeding have we saved their lives, and after three seasons seen a flower-spike on that group. It shows well what can be done in restoring to health a moribund specimen. The satisfaction of slashing a pucey Giant Lily is not confined to ravens, however, for one of our greatest living gardeners told me a tale of mingled joy and woe that always recurs to my mind when I see a fine spike of this Lily. It happened in his tender youth that his father, the Director of one of the most beautiful botanic gardens in Europe, was regarding as the important garden event of the year the flowering, for the first time there, of a group of Giant Lilies. The spirit of Jack the Giant Killer descended upon the

PART OF A NEW ZEALAND ROCK GARDEN. THE PLANTS SHOWN ARE NATIVES OF THAT COUNTRY.

cordate leaves increase in beauty each season till, after their fourth, there are few plants to match them in the outdoor garden, *Richardia ethnopica*, the white *Arum* of common speech, being perhaps their nearest counterpart in the greenhouse. If the seedlings have been well cared for in a cold frame for their first two years, they can be planted out in their third spring. They soon make a beautiful foliage group, and in six to eight years most of them should be strong enough to throw up 10 feet of flower-stem with twenty or more of their magnificent trumpet-shaped flowers. I am very fond of their fragrance, which always strikes me as being of a similar type of scent to the Honeysuckles, with that same suggestion of custard with grated nutmeg on it. Of course, it is magnified Honeysuckle, as betwixt such a large-flower, and carries to a wonderfully great distance, which is one of its greatest charms, for it is delightful to get whiffs of it on the summer air. When buying bulbs, I strongly advise selecting

being overhung and the consequent drip, and also being robbed of their due of soil fatness by hungry, thieving roots. The soil should be well drained, and enriched that the strong roots may go far ahead and find juicy food throughout the growing season.

Miss Jekyll has so well described her method of planting the Giant Lily at page 97 of "Home and Garden" that I cannot do better than quote it: "Here . . . their beds are deeply excavated, and filled to within a foot of the top with any of the vegetable rubbish of which only too much accumulates in the late autumn. Holes 12 feet across and 3 feet deep are convenient graves for frozen Dahlia-tops and half-hardy annuals; a quantity of such material chopped up and tramped down close forms a cool subsoil that will comfort the Lily bulbs for many a year. The upper foot of soil is of good compost, and when the young bulbs are planted, the whole is covered with some inches of dead leaves."

future knight, and, fashioning a lath sword, he fought a fierce and sappy battle with the Giants, ending in complete victory to the boy and utter ruin to the vegetable enemy. He still remembers with equal vividness the wild joy of overcoming the succulent resistance of the Lily stems and the painful interview with his father that formed the sequel to the Battle of the Giants.

Even now, in late December, at the moment of writing, there is great beauty in the tall bare stems and seed-pods standing sentinel among *Asarums* and dwarf evergreens, and while still clad with the glistening leaves, gradually diminishing in size as they ascend the stem, and crowned with the vivid green seed-capsules, which stand erect with a particularly striking effect of vigour and stability, few plants give so noble an architectural outline in the hardy flower border.

E. A. BOWLES.

(To be continued.)

ROCK AND WATER GARDEN.

RANUNCULUS LYALLI IN NEW ZEALAND.

I AM sending you a photograph of a portion of the rockery here devoted entirely to native plants. In the foreground are several varieties of *Celmisias*, on the left *Ligusticum brevistyle*, and in the background *Ranunculus Lyalli*. I am surprised the latter is not grown more in England, as, given a good strong loam, good drainage and a fair amount of water in summer and a heavy mulching of spent hot-bed manure in winter, I see no reason why it should not do well. R. Matthews (a very rare species is one that should do well, as I find it flowers much quicker after collecting than *R. Lyalli*; in fact, one plant I got two years ago flowered twice last season—in early spring and again in autumn. I shall have a limited amount of seed of *R. Matthewsii*, also a quantity of seeds of alpines, *Veronicas* and similar plants, which I shall be glad to exchange with any of your readers for seeds of alpines from the Northern Hemisphere.

WILLIAM WILLCOX.

Queenstown, Otago, New Zealand

SAXIFRAGE CLIFFS IN ROCK GARDENS.

Of the many methods of growing Saxifrages, I have found none as satisfactory as the "chiff" method. When properly built the Saxifrages nestle into it, soon filling its cracks and chinks with their tight, silvery cushions. Even the hottest sun seems unable to scorch them or to dry up their roots, which run far back behind the protecting ledges of stone, and the heaviest rain fails to rot their centres, as they are all growing in vertical positions, and the water cannot lie on them.

Such chiffs are not difficult to make; any projecting "nose" of the rockwork can be adapted, and stones too small or ugly to be worked into the general scheme of the rockwork can now be utilised. The stones, which must be built into the face of the rock bank, are placed on top of one another, with a little light, gritty soil sandwiched in between. They should not be too far apart. If you consider the stones as bricks, and the layer of soil as the mortar between them, you cannot go far wrong. Having built in your first stratum of stones and covered their tops lightly with the soil, next select your Saxifrages—two or three plants of a kind, if possible—knock them out of their pots, shake a little of the soil from their roots, slightly flatten the latter with the palms of your hands, and then lay the plants on top of the stones in such a manner that their foliage only just clears the edge; then sprinkle a little more soil over the roots, place another stone on top and press it down, taking care that its lower edge does not overhang the stone

beneath it, but recedes slightly from it. This is necessary to enable moisture to reach the roots. If the plants are put in in this manner while the chif is being built, it is astonishing how soon they are at home and how rapidly they grow.

On a chif made as recently as March, 1912, which is about five feet high and projects from a south-east corner of rockwork, I have at the bottom plants of *S. rocheana lutea*, and immediately above these *S. sancta speciosa* and *S. Paulina*, higher up *S. Ferdinand-Coburgi*, and on top of the white stone *S. Borisi*. Above this, on the left, is *S. scardica*, one of six plants of *S. longi-*

THE FRUIT GARDEN.

THE BEST PLUMS AND THEIR CULTIVATION.

WHILE the exact identification of the "forbidden fruit" remains a matter of speculation, I have no hesitation in designating the Plum the "unappreciated fruit." The extended culture of the commoner varieties for "market" purposes has perhaps to answer for the lack of appreciation of this most delicious fruit; but I also venture to think that a lack of care in gathering at the right season and storing for a short interval are likewise partly responsible for its neglect.

The Plum has long been reproached with unfruitfulness; but we are now able, thanks to recent research at the John Innes Horticultural Institution, to remedy one frequent cause of this first of deadly sins. I allude to the fact that Plums are generally self-sterile; that is, pollen must be brought from another variety to ensure the perfect setting of their fruit. This is a valuable piece of information to gardeners—and nurserymen.

Another cause of infertility is the destruction of blossoms by spring frosts. Considering the ease with which this may be combated, by throwing over the tree a piece of netting, I wonder it is not more practised on dwarf trees. Most gardeners, however, allow a certain wall space to the choicest varieties, where protection is easier still. It is a common complaint that the Plum in its earlier stages makes too much growth. This should be remedied by the culture of pyramids and bushes, when occasional transplanting for the first ten years will ensure an abundance of fruiting spurs. It must also be remembered that this fruit is a lime-loving plant, and needs a good supply always at hand, or should I say at the root?

Plum orchards may be seen thriving on the Southern chalk downs with the thinnest of surface soils. Of varieties there is a wide choice, and I will mention but a few of the best. First of all comes Oullin's Golden Gage, a large yellow fruit, excellent for dessert, and for bottling one of the very best. August brings the Early Transparent Gage, small, but certainly highly flavoured. September is the Plum month, and many are at the disposal of the gardener. The Green Gage, Transparent Gage and Jefferson are all sorts that no self-respecting gardener can dispense with, while for the kitchen, and also for the boys home from school, Victoria, the ever-cropping, and Belle de Louvain are desirable. Late varieties are found in Golden Transparent and Coe's Golden Drop. It is not generally known that the latter can be kept for a long period in the fruit-room.

LILIAM GIGANTEUM IN MR. E. A. BOWLES' GARDEN AT WALTHAM CROSS.

folia, and, just peeping over the top, *S. dalmatica*. On the right from the bottom are *S. longifolia* and *S. Oubristii*, above *S. thessalica*, and near the top *S. tombeana* and *S. Aizoon minima*. All are the picture of health and growing vigorously, and I strongly recommend this method to all who grow Saxifrages. On a similar chif a few yards away, built two years ago, the plants here completely covered its face, and are crowding each other to such an extent that I shall have to harden my heart before next growing season and thin them out.

Knapton Abbeylea. MURRAY HORNIBROOK.

For late cooking purposes Monarch and the newer President are most valuable.

Those whose gardens are in sheltered spots, and where spring frosts are not troublesome, should grow a tree or two of the Myrobalan, of which there are two varieties—yellow and red. The tree flowers very early and is decorative, so that even if it fails to crop, it justifies to some extent its existence. The fruits when bottled are excellent, but must not be gathered too ripe, or they will be mealy. This must not be confused with the Mirabelle of the Continent, which is of the Gage tribe and noted for its excellent jam-making properties.

To those who have glass at their disposal, pyramid trees in pots can be strongly recommended. As decorative specimens when in flower and fruit they are most beautiful, and the fruit attains a richness of flavour not often equalled by outdoor trees. No heat is necessary, and they will be over in time to allow the house to be used for Chrysanthemums—a further point in their favour. E. A. BUNYARD.

THE GREENHOUSE

WINTER-FLOWERING GREENHOUSE HEATHS.

At one time collections of greenhouse Heaths formed a prominent feature of many gardens, but with the decline in popularity of hard-wooded plants in general, many of the Heaths disappeared from cultivation. A few kinds, however, are still grown, and as a rule in very large quantities, for some of the nurserymen who make a speciality of them generally devote the greater part of their energies to these greenhouse Heaths and similar plants, such as Boromas and Epacris. Delightful little specimens of these may frequently be seen in the florists' shops, especially during the autumn, winter and early spring months, the summer-flowering kinds being, naturally, not so much in demand, though of them the attractive *Erica verticosa* is still grown. After the summer is over, the Heath season may be said to begin with *E. gracilis*, a dense, twiggy little bush, whose tiny rosy-purple flowers are borne in great profusion. Several varieties of this Heath are in cultivation, namely, *rosea*, in which the purple tinge of the flower is almost wanting, it being of a pleasing rosy shade; and *vernalis*, of more sturdy growth than *gracilis* itself, and much later in flowering. There are two white or pale-flowered kinds, namely, *alba*, the oldest, in which the blossoms often have a pinkish tinge. They are decidedly less pure than those of *vernalis*, which is now extensively grown.

After *E. gracilis* comes *E. hyemalis*, a great favourite, and always in considerable demand about Christmas-time, when model little plants in 3-inch pots can be purchased at a comparatively

cheap rate. There is a variety of this known as *superba*, whose flowers are deeper coloured than those of the type, also a variety *alba*, in which they are pure white.

Another winter-flowering Heath that has come prominently forward within the last decade or so is *E. melanthera*, which may be grown into larger specimens than any of the others. The flowers of this, which are borne in great profusion, are small and of a distinct mauve colour, with blackish anthers. The low-growing, white-flowered *E. cafra* is also grown to a limited extent.

Of those that as a rule bloom somewhat later than the preceding, but yet may well be included with winter-flowering Heaths, are *E. willmoreana*, somewhat in the way of *E. hyemalis*, but of a more robust, spreading habit; and *E. persoluta alba*, with

best covered with a bell-glass, so that the size of the pots or pans will depend upon that of the bell-glasses available. Whether pots or pans, they must be filled to within an inch of the rim with broken crocks, coarse at the bottom and very fine on the top. The soil should consist of peat and sand passed through a sieve with one-eighth of an inch mesh, and made very firm and smooth. In inserting the cuttings, each one must be made quite firm, and though space should not be wasted, overcrowding must be avoided. A length of about an inch is a suitable one for the cuttings, in preparing which a very sharp knife is essential. When a pot is filled, it should be watered through a very fine rose, allowed to drain, and then be placed in a snug part of a warm greenhouse, taking care that the cuttings are shaded from all direct sunshine.

When rooted they must be potted off, the subsequent treatment being a matter of detail. It must, however, be borne in mind that it takes nearly three years to obtain a good plant, and this circumstance renders the cheap price at which flowering examples are sold very surprising.

Where it is intended to keep the old plants after flowering and grow them on another season, they should, when the blossoms are past, be cut back hard, and as soon as the young shoots make their appearance the plants must be repotted, giving them in most cases a pot one size larger than before. The soil should be peat and sand, pressed down very firmly, and especial care must be taken when repotting that the ball of earth is not dry, otherwise it will be almost impossible to moisten it in a satisfactory manner. H. P.

A SEASONABLE NOTE ON AURICULAS.

So far the plants have been kept strictly on the dry side, but soon the days will begin to lengthen and the Auriculas will show signs of renewed activity. Towards the end of the month the collection ought to be looked over, all decayed leaves removed and the soil slightly stirred with a pointed stick. There is no need to take away an inch or so of soil and replace with a rich compost, as was

the case in the old days. All offsets may be taken off, whether they are rooted or not, and those with roots can be potted singly in 3-inch pots. Any without roots should be placed around the edge of a pot, where they will soon become established, when they can be treated as larger examples. If the weather keeps open and mild, more water ought to be given; but even at this period they must not be kept too wet, or the roots will decay and the quality of the blooms suffer later on. Plenty of air must be allowed at all times; but now that growth has recommenced and the spikes beginning to appear, it will be advisable to cover the frames with Archangel mats should frosts make their appearance. The weather has been so mild up to the present that, unless they receive a check, the Auriculas will probably flower earlier than usual. S.

A WHITE-FLOWERED HEATH (*ERICA GRACILIS ALBA*).

a profusion of tiny white bells, gracefully disposed. Within the last few years miniature plants of some of these Heaths, particularly *E. gracilis*, *E. cafra* and *E. persoluta alba*, have made their appearance in the florists' shops and met with a ready sale. The smallest of these are struck in the spring and allowed to go on and flower without stopping.

Cultivation.—All the different winter-flowering kinds alluded to belong to what are termed soft-wooded Heaths, from the fact that they are readily propagated by cuttings of the soft-growing shoots; whereas many of those that used to be grown as large specimens could only be increased by cuttings of a firmer nature. These soft-wooded cuttings etc., as might be supposed, very delicate subjects to handle; hence everything should be prepared before they are taken in hand. They are

HOW TO REPAIR HOLLOW TREES.

THIS is a subject worth more attention from the owners of those who have the care of trees. It is a matter for the small garden with a few trees as well as for the pleasure grounds and parks where the trees may be counted by hundreds. The causes or origin of wounds or decay in trees are varied. Branches broken off by wind usually leave a stump or a splinter of a piece of the larger limb to which it was attached. In both cases decay will almost inevitably follow, unless means are adopted to check it. Snags or stumps should be sawn off close to the remaining branch or to the trunk. After sawing, the rough surface caused by the teeth of the saw should be gone over and pared with a sharp knife, to provide a better surface for the tar. All wounds made on trees, whether through accident or the removal of branches in the training, pruning, or balancing of a tree, should be coated with ordinary cold-tar.

Historical Trees.—The life of famous old trees and grand specimens is sometimes considerably shortened by disease, which, if checked or even cured, would have considerably prolonged their existence. Before filling up a hole or cavity in a tree, the hollow must be thoroughly cleaned out. Damp, rotten wood attacked by fungus, or soft, crumbling wood must be first cleaned out, removing it with a chisel or small axe till only dry, hard wood remains. One or two dressings of carbolic acid solution should then be applied to destroy, if possible, all traces of disease. In a day or two a coating of tar should be applied and allowed to dry. The nature and extent of the hollow will

1. A WOUND IN A CHESTNUT TREE CAUSED BY THE REMOVAL OF A BRANCH.

2. THE HOLLOW FILLED WITH A MIXTURE OF CEMENT AND SAND.

decide the method of filling it. Small holes may be filled with a mixture of cement and sand, or, if round and a fair depth, an Oak peg coated with tar may be driven in and cut off flush with the trunk.

Bricks and mortar, together with concrete, are the best materials for filling up large hollows. It is sometimes necessary to build up a face with bricks, and fill in behind with concrete as the work proceeds. One tree—a Beech—with which we had to deal was hollow on one side, from the ground to a height of 21 feet. In this tree eighty-four courses of bricks were built up—some three hundred bricks in all—with concrete behind and a facing of cement over the bricks. Another tree—a Walnut—took nearly a ton of concrete, but in this case the shell of the tree held it together without the aid of many bricks. Before attempting the work of filling up large holes, make sure that the tree is not dangerously weakened through decay.

Those readers who have not had much to do with trees will probably say, "Why let the hollows get so big before filling them up?" In some cases the large holes are, of course, due to neglect in the earlier stages, but the decay goes on in some instances unnoticed within the tree.

The wound in the Chestnut illustrated was caused through the removal of a large branch, and before the wound could heal right over, decay started in the centre. The new bark is plainly visible growing on either side of the hollow, and in time it should grow over the cement and meet. For this reason it will be observed the filling-in material has only been brought level with the new bark, and not flush with the trunk. For important work of this kind the gardener will often find it necessary to call in the aid of a bricklayer. With a little practice the varying colours of the wood can be obtained by lamp-black, soot, or a little dry cement being sprinkled on when wet. The markings of the trunk can also be imitated by a skilled workman. It is necessary to watch the wounds and "stopping" occasionally, tarring over the former every two or three years till quite healed over.

The carbolic acid solution is prepared by mixing a quarter of a pound of carbolic acid and one gallon of methylated spirit.

THE TRUNK OF A SILVER BIRCH TREE BEFORE AND AFTER REPAIR.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Propagating Bedding Plants.—Where only small stocks of such plants as *Coleus*, *Iresine*, *Lobelia*, *Mesembryanthemum*, &c., are wintered, the work of propagation should be commenced at once. The cuttings root quite freely at this date, and, once rooted, the work of hardening them off is much more easy than later, when strong sunshine has a tendency to make them flag for a considerable time, unless, of course, the syringe is kept going pretty freely over them.

Zonal Pelargoniums that may have been rooted singly in small pots or in boxes in the autumn should now be potted off as time and available space permit, using the size pot that may be most suitable for their proper development, remembering that a plant started in a small pot takes a longer time to get over the shift when removed to its summer quarters than one in the full vigour of growth, the loss of foliage in the former case proving an eyesore for a considerable time.

Plants Under Glass.

Malmaison Carnations.—If not already done, autumn layers of these beautiful flowering plants should be potted into their flowering pots at once, which, by the way, should be of 6 inches. Good friable loam, spent Mushroom manure, a little bone-meal—a 4-inch potful to a wheelbarrowful of soil—a good sprinkling of wood-ashes and lime rubble, with sufficient coarse sand to keep the whole porous, should suit them well, making them pretty firm during the operation.

Arum Lilies.—These are now growing freely, and if a good crop of large blooms is required, plenty of water and manure must be given them, and a dressing of some artificial manure might be given at least once every fourteen days. These plants, being somewhat subject to green fly, should be fumigated occasionally. This is sometimes thought expensive, but in the long run it is much cheaper than sponging.

Lachenalials.—If a batch of these is required in bloom fairly early, they may be placed in a house with a night temperature of 50° to 55°, but not warmer. Those still in cold frames should be removed to the shelf or stage of a light, airy and cool house, where the foliage will get much more robust, and with the aid of a little liquid manure the flower-spikes should come strong and of good colour.

Chrysanthemums.—Cuttings propagated during late November and December under cool conditions should be making roots nicely, and when found to be doing so should be removed to a frame or house where the conditions are less close, and where air can be admitted in increasing quantities as the young plants attain hardiness. To prevent flagging during bright weather, the plants should be very lightly sprayed overhead. A further batch of cuttings for large blooms may be put in, selecting those varieties that from earlier propagation produce flowers a little too early for November blooming. These include such varieties as *Master James*, *Mrs. A. T. Miller*, *Frances Jolliffe*, *White Queen*, *Mrs. L. Thorn*, *Mrs. R. Luxford*, *Evangeline*, *Mrs. Loomes*, *Kara Dow*, *Japan* and *Miss Gladys Herbert*.

The Kitchen Garden.

Asparagus.—Where a regular supply of this has to be kept up weekly or bi-weekly, batches should be placed in the forcing pit or house, covering the crowns over with 3 inches or 4 inches of leaf-mould or light, sandy soil. A bottom temperature of about 60° to 65° should be maintained either by hot-water pipes or by well-prepared hot-bed material, which will sustain a good quick growth.

Seakale.—A good supply of this should also be kept up, varying the amount according to requirements. Where a Mushroom-house or other specially-constructed place is not to hand for the forcing of Seakale, and Rhubarb, the supply may be kept up by placing from six to nine roots in 12-inch pots, inverting another pot over the top of each. These roots, if placed under a stage in a warm house, will soon be fit for use. The whole batch of forcing Seakale should now be lifted (if not already done) and thinned.

Fruits Under Glass.

Pruning Peaches in Successional and Late Houses.—Presuming the trees have been gone over after fruiting, the pruning should not be a serious matter; but before cutting them free of the wires they should be gone over carefully, taking out all wood that is not absolutely necessary for the proper furnishing of the tree, discriminating, of course, in favour of the younger wood, unless this be of too luxurious a growth. Peaches and Nectarines are often left too thickly. From 4 inches to 6 inches is quite close enough for the wood, for it has to be borne in mind that when growth commences there is bound to be two shoots for one at least, and these covered with foliage.

Orchard-House Trees of Apples, Pears, Plums, Apricots and Cherries should still be kept quite cool unless they are wanted very early, as undue hastening of the flowering period is apt to result in weak flowers and a poor set of fruit.

The Hardy Fruit Garden.

Pruning.—Continue the pruning of hardy fruit as time and weather permit, going from the wall trees when they are finished to the more exposed trained trees growing round the paths in the garden.

Pears.—On our cold soil I find there are certain varieties of Pears that will not stand really hard or close pruning, owing to the shoots dying back when pruned, and these include such varieties as *Beurré d'Amant*, *Olivier des Serres*, *Beurré Superfin*, *Eastar Beurré*, *Josephine de Malines*, *Winter Nelis*, *Beurré Alexandre Lucas* and *Louise Bonne* of Jersey, so when pruning these, either during summer or winter, I leave the growths about two inches longer than those of the ordinary varieties.

Apples.—Certain varieties of Apples are also much more shy when grown as trained trees than as standards, and such varieties often carry a crop of fruit-buds that are at the apex of small shoots, say, from 6 inches to 8 inches in length, such shoots often springing from beneath the fruit. If these shoots are left, they will often give a crop of fruit when there are no short fruit-buds formed at the base of the spur, and varieties I have noted cropping in this way are *Gascoyne's Scarlet*, *Cornish Gidflower*, *Golden Pippin*, *Irish Peach*, *Old Nonpareil*, *Mr. Gladstone*, *Gloria Mundi*, *Hollandbury* and *Kentish Follbasket*.

THOMAS STEVENSON

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Sowing Sweet Peas.—This should not be much longer delayed. Equally good results may be obtained either by sowing in pots or boxes, the latter method being more convenient. Sow in rows about three inches apart, and an inch apart in the rows. Well-ripened seed from a healthy, well-grown stock is the best guarantee for satisfactory germination. Seeds must be guarded against, either by coating the seeds with red lead, by covering the boxes with sheets of glass, or by laying poison near. The last-named precaution will be necessary after germination takes place in any case. Place the pots or boxes in a frame or cold pit.

Bedding Plants.—Stock should now be placed in heat to supply cuttings later on. Geraniums should have their growing points pinched to induce a stubby growth prior to potting or boxing off.

Dahlias should have their tubers shortened and the dead parts cut away, then be placed in heat in order to furnish cuttings. Spray them daily after the first week to induce them to break vigorously.

The Rock Garden.

Additions.—Any constructive work should be pushed forward, so that the work of planting (best done in autumn) may be proceeded with as early in spring as possible.

Protection.—Treasures such as *Daphne blagayana* are well worth the trouble of placing a bell-glass over them to keep them clean. The glass should be set on two bricks to admit abundance of air. The finer varieties of the *Lenten Rose*, too, will be benefited by the protection of a hand-light. Mice are fond of the flower-buds of the lighter-coloured varieties, and should be trapped or poisoned.

The Shrubbery.

Lilacs.—These often throw up a lot of suckers, which, if left alone, draw up weakly, doing no good to themselves and robbing the main stem of nutriment. If the plant is grafted, the suckers should be removed and burnt. If, however, it is a desirable variety on its own roots, some of the strongest suckers may be planted in the reserve garden for subsequent planting.

Plants Under Glass.

Winter-Flowering Begonias.—As these go out of bloom they should be headed back to induce them to make cuttings. A slight spraying daily will assist in the process.

Perpetual-Flowering Carnations.—The propagation of these plants must now be proceeded with, and this is the time for those who have not yet attempted their culture to make a start.

The Cuttings should be taken off with a heel and inserted round the edge of 3½-inch pots, six to a pot. A compost of loam, leaf-mould and sand is suitable for the purpose. Place the pots in a propagating-case where a night temperature of 60° is being maintained, and the cuttings will be rooted in about three weeks.

Gloxinias.—If seedlings are expected to flower in the autumn, a sowing should now be made. Use a well-drained pot or seed-pan, and fill it with a mixture of loam, peat, leaf-mould and sand. Make the surface quite smooth, and water with a fine rose. After two hours the seed may be sown, and, being very fine, it should first be mixed with some sand to secure equality of dispersion. Do not cover with soil, but place a pane of glass over the pot or pan and insure to air as germination takes place.

Fruits Under Glass.

Melons.—If not already done, a sowing should now be made if ripe fruit is expected by the beginning of June. One seed to a pot is good practice; but if room is scarce, I find that a batch can be sown in a pot or pan and duly potted off into 3½-inch pots, with equally good results. A bottom-heat ranging from 75° to 80°, with 5° less of top-heat, is necessary to keep them going smartly, and this is very necessary with a naturally succulent, quick-growing plant like the Melon.

Orchard-House Fruits.—A start may now be made with Pears, Plums, Cherries and any other orchard-house fruits. Begin to force gradually; in fact, if the house is kept close, no fire-heat will be necessary for the first fortnight, provided the weather is mild.

Figs may be started with a night temperature of about 50°, with a rise of 5° during the day in dull weather and 5° to 10° more with bright sunshine.

The Hardy Fruit Garden.

Loganberries are acceptable to most families, as they can be utilised in various ways—uncooked, stewed, or as a jelly. Moreover, in soils such as I have to deal with—a heavy clay—where Raspberries do not succeed well, they form a welcome substitute for, or addition to, that crop. Those who purpose making a plantation should trench the ground and give it a liberal manuring prior to planting, then little working of the soil will be required for several years. By far the best method of training is on a double trellis 1 foot apart, training the fruiting canes up one side and the succession ones the other, and transposing them annually.

The Kitchen Garden.

Early Carrots.—Fermenting materials should now be prepared for making up a slight hot-bed, and an early sowing of some of the stump-rooted varieties, such as *French Short Horn*, should be made.

Early Turnips.—Preparations similar to those directed for early Carrots should also be made for an early sowing of this crop, where such is in demand. *Early Milan* or its white variety is suitable for this purpose.

Onions.—If not already attended to, not a day should be lost in getting in the seed of these. Sow in boxes of turfy rich, finely-sifted soil, and place in a vinery at work. *Ailsa Craig* and *Cranston's Excelsior* are the varieties to sow where big bulbs are wanted.

Lettuce.—A small sowing should be made in a house with a temperature ranging from 50° to 55°. Use a quick-bearing Cabbage variety.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mans, Midlothian.

NEW AND RARE PLANTS.

AWARD OF MERIT.

Lindenbergia grandiflora.—This might not aptly be styled the "Tree Musk," so nearly do the flowers in size and colour and form approximate to the popular plant indicated. The example shown was 2½ feet high, and had been flowering for some three months in succession. It is by no means a novelty, having been known to cultivation for many years, though, with many others, apparently almost lost. The plant has a bushy habit of rather woolly leaves and stems, and almost from base to summit is furnished with a profusion of yellow Musk-like flowers. As a winter-flowering subject it is worthy of attention. From Messrs. James Veitch and Sons, Limited, Chelsea.

NEW ORCHIDS.

There was no lack of novelties brought before the Orchid committee of the Royal Horticultural Society on January 7, when the foregoing award and those following were granted. Only one first-class certificate was awarded, and this went to a remarkably fine form of *Odontoglossum Pescatorei* named *Sanderia*, which was shown by Baron Bruno Schröder. There were three new *Cypripediums* to gain awards of merit: *C. Amazon*, from F. Menteth Ogilvie, Esq.; *C. Iona*, from His Grace the Duke of Marlborough; and *C. Alcinda*, shown by Messrs. Charlesworth and Co. Other novelties to secure awards of merit were: *Laelia anceps* *Roeblingiana*, shown by C. J. Roebling, Esq., of New Jersey; *Odontonia Firminii*, from M. Firmin Lambert; *Habenaria Roeblingii*, shown by F. H. Davidson, Esq.; and *Odontoglossum* George Day, from H. S. Goodson, Esq.

THE MISUSE OF MANURES.

DOUTLESS the majority of the readers of this journal have heard the story of the old gardener who, on a visitor enquiring of him for the head-gardener, took him to the manure heap. I have never been able to see anything either humorous or clever about this, as anyone who allows manure to be master must have a very poor idea of the profession. That manure is an indispensable item in good gardening no one will deny, but its indiscriminate use does far more harm than many suppose. Instead of calling the manure heap the head-gardener, I would term it an excellent assistant, if kept in its proper place. For instance, the production of good Celery, Onions, Leeks, Peas, Beans, Cauliflowers and Brussels Sprouts depends to a considerable extent on the judicious use of manure, while Beet, Carrots, Potatoes and a few other vegetables will simply be ruined if manured on the same liberal scale. It is in cases of this kind where intelligent experience is a necessity.

There can be no doubt that a great amount of manure is annually wasted through ignorance or carelessness. This applies more especially to the artificial compounds that are now in common use all over the country, as, with the advent of the motor-car, the amount of stable manure is now considerably reduced in quantity. Naturally, the amateur is the greatest sinner in this respect, although I am ashamed to say that many professional gardeners, in their hurry to make things

grow, not infrequently use their artificials in too strong doses, and thus over-reach themselves. It never seems to strike these people that the vendors of these compounds invariably advise the maximum safe quantity to be used, or at least the proper quantity, to give best results. If the directions are faithfully followed, the great bulk of the manures offered will give satisfactory results. I am no chemist, so do not pretend to know much about the various ingredients that go to make up the different artificial fertilisers on the market, but from a long and careful study of the wants of the various plants I have been able to secure quite good results in the majority of cases.

I have heard numerous discussions on the subject of artificial manures, many holding that they are excessively expensive, and that one would save considerably by mixing their own manures. I do not believe this to be practicable, as who is to decide as to the ingredients, their proper proportions, and other points? For one have no time, nor inclination, for carrying out a series of experiments so as to decide the question, and will continue, as I have done for twenty-five years, to rely on one or two of the standard preparations on the market.

In past years I have tested in a small way a great number of the proprietary fertilisers, and found that the majority had their good points, if strict attention were paid to the directions supplied by the makers. I have always tried to be as exact as possible, both with quantities and times of application, and consider that in most cases the results justified the expenditure. For pot plants, to my mind, a good sound artificial manure gives far better results than the use of natural manures ever do, and with about a quarter of the trouble. While I have proved this, to my own satisfaction at least, I am well aware that a careless use of these chemical stimulants may easily result in disaster, but the same may happen if the plants be dosed with too strong liquid manure. On the other hand, I have no great reliance to place on artificial manures when used alone for flowers, fruits or vegetables in the open garden.

Good farmyard manure used in moderation and supplemented with a light dressing of a good artificial will in every case give excellent results. Over-manuring is not only wasteful of material, but causes waste through the crops being coarse and unfit for use, and not infrequently either kills plants directly or, by forcing them into sappy growth, causes them to succumb to frost or damp. It would be easy to dilate further on the evils of over-manuring, but enough has been said, I hope, to cause the careless to take thought on the subject, and so avoid this most undesirable mistake.

Preston House Gardens, Lillithgow. C. BLAIR.

THE "WOBURN" PLANTING OF FRUIT TREES.

IN an article contributed to *Science Progress* by Mr. Spencer Pickering, F.R.S., the Director of the Woburn Experimental Fruit Farm, among other interesting matter the author gives some account of experiments in tree planting, both by the ordinary accepted methods and by his new plan of "ramming." As he claims to get such excellent results from his method, so much superior to those following upon ordinary planting; moreover, as his method might without offence be described as "careless," and as the success of

"careless" planting (as that carried out with much care may encourage growers to still more slipshod methods than they adopt at present, it may be as well to examine carefully what has been accomplished and what is claimed for it.

The author starts the consideration of "ramming" with the thesis: For the development of the dormant root buds, as they may be termed, intimate contact between the roots and the damp soil is essential. No thoughtful planter will quarrel with this, as the aim of every such person has been to tread the soil as softly as possible when the roots have been covered. He goes on to say, however, that "much more intimate contact between the roots and soil can be secured by ramming the soil around the tree, as in fixing a gate-post, especially if the soil be wet at the time"; and, further on, "Planting with ramming can be safely practised, however wet the soil may be, and at a time when planting in the ordinary way would be out of the question, ramming to the extent of puddling the soil being no disadvantage." Here I think we should, many of us, part company with the author, in spite of the experiments he has carried through and which seem to point this way. In the first place, it is quite possible that ramming a light sand when wet might not permanently harm it, but if such treatment were applied to a heavy clay, on the approach of spring with its drying winds, all the soil which had been treated to this "puddling" would dry like bricks, and one can scarcely conceive of fruit trees thriving under such conditions.

Another point is the absolute impossibility of any aeration going on in soils which can be described as "puddled," a condition which, one would think, could not be anything but harmful, in view of the late discoveries concerning bacteria and their requirements.

Can it be possible that unconsciously Mr. Pickering and his assistants who carried out the experiments have treated the trees planted by the ordinary methods too gingerly, and that they have not really been planted sofly enough?

Next we come to the question of the treatment of the roots, and here again the author departs from accepted practice a good deal. He says: "Whether the end of a broken root be trimmed or not appears to make no difference to the welfare of the tree," and he bases his argument upon the fact that "only 15 per cent. of the new roots of trees were formed within a quarter of an inch from the old root ends"; but surely this does not affect the matter. We do not cut away a jagged end of a root primarily with a view to root formation, but in order that the tree may quickly heal and protect the wound, a result more and more necessary in these days when animal and vegetal pests inhabit the soil and prey upon the roots as well as the branches. It seems to me that one might as well say that a broken branch need not be cut back because shoots did not arise from a certain distance from the fracture. Another passage runs: "Shortening of the roots up to one-third of their length (but not more) has been found to be of slight advantage rather than the contrary." It is difficult to see exactly to what this refers, but one must suppose it is the length of the root as fitted with great care—that is, the maximum length of root it is possible to get out—that is meant. If the roots of trees—as they are often, unfortunately—fitted in commercial places were submitted to this drastic shortening, there would be but very little root left. I fancy that quite as drastic a shortening of the roots is done on a market place as an ordinary matter of course—that is to say, the roots is planted

are but little longer than Mr. Pickering's, though the actual cutting back is not so severe, and that anything further in this direction would be unwise. In the same way, I think that a proper planter with his gang on a market-grower's place makes his trees quite as solid by his treading as the author does by his ramming, and so achieves much the same results. The personal element enters so largely into this sort of thing, where there is no means of actually checking all the conditions, in this case the density of the soil arrived at by the different methods of "treading" and "ramming." I venture, with all diffidence, to suggest that these are some of the reasons for the rather startling set of results Mr. Pickering claims for his experiments. X.

PLANTS FLOWERING OUT OF SEASON.

ALTHOUGH the calendar declares the date to be the early half of January, the birds and flowers of this garden insist that it is at least the latter half of February. This is so unexpected to me after so cool and damp a summer that it seems worth recording and endeavouring to account for it. Last December was the warmest known since 1868. Dr. H. K. Mill, in a letter to *The Times* of January 3, gives the mean temperature of the past December as 49.8° and that of 1868 as 50.0°, one-fifth of a degree higher. But the mean of the highest daily temperature of December, 1912, is 50.8°, whereas it was 50.7° for 1868, and so stands higher for 1912 than has been yet recorded.

That, of course, is a large factor in this unseasonably rush to be first in flower; but I think we must look still further back for other causes to account for the extreme earliness of some plants. For instance, *Eranthis hiemalis* was in full flower here in the third week of December, making the ground green and yellow where the larger colonies grow; but the blossoms were thin and poor, as they always are when early. Gerard knew this, and expresses it thus in his pleasant Old English: "Yea the colder the weather is, and the deeper that the snow is, the fairer and larger is the floure, and the warmer that the weather is, the lesser is the floure and worse coloured." I take it that when delayed below ground and then rushing up with the thaw, the flowers are better matured and have lost that thin texture and greenish tint which are also so characteristic of an over-forced *Daffodil*.

But more marked still in this garden, and I hear almost everywhere else, is the early flowering of the Lenten Hellebores, *H. orientalis* and kindred kinds. By mid-December they were in full bloom here, and taller and handsomer than they usually are even as late as early March. They had not rushed out, but had come along quietly and steadily for months. There were sharp frosts in early November. Here we registered 11° or 12° on several nights, and when this spell of warmth followed, the plants seem to have been persuaded the winter had come and gone, and grew in a rapid manner, somewhat akin to plants that have been retarded in cold storage or etherised. It is well known that Rhubarb forces better after being frozen, and entomologists who wish to force pupa find that it is better to let most of them, at any rate our truly Northern species, feel a touch of cold before putting them into heat, or, instead

of being hurried into emergence, they may be induced to lay over to another season.

I am, however, inclined to think that the greatest amount of preparation for early flowering this season must be attributed to the extraordinary absence of rain in April and early May of last year, which hurried up and stunted the Darwin Tulips so markedly, robbing them of much of their beauty in all but deeply-dug and cool soils. I noticed how *Crocus* leaves ripened and disappeared quite six weeks earlier than usual, and it was the same with Snowdrops, and that, I feel sure, is the prime cause of my having *Galanthus byzantinus*, *Imperati* and several early seedling forms of *ivalis* well out in bloom before Olga was over. And the list of Croci in flower in the open ground in Christmas Week included *C. Imperati*, *Sieberi*, *dalmaticus*, *tommasianus*, *ancyrensis*, *chrysanthus* in about a dozen varieties, *Korolkowi*, *alatavicus*, *cypricus* and *aureus*. Now, in the second week of January, most of the species that should be out in mid-February are full of flower, but the dull, wet days forbid their opening properly, and I feel I am being cheated by the Clerk of the Weather of my proper enjoyment of the *Crocus* season. *Iris sphenensis* and *histrionides* were both in full flower before Christmas. I deplore this unseasonable blooming, but to compensate for it such subjects as *Iris unguicularis*, *Chimonanthus fragrans*, *Lonicera fragrantissima*, *Correa magnifica* (on a wall), *Brassica insularis*, *Garrya elliptica* and other naturally winter-flowering plants have never been finer, and a source of great enjoyment. *Iris unguicularis* and *Chimonanthus* must have prepared for this flowering early in last season, and are noteworthy, as their tree production of flowers is usually associated with a previous hot summer. Thus it appears to me that a dry spring hastened the ripening of certain plants, early frosts deceived them with false hopes of troubles past, and an unusually mild December gave them no further warning of troubles ahead.

Waltham Cross.

E. A. BOWLES.

BOOKS.

Fruit-Growing for Beginners.*—The ranks of gardeners are constantly being augmented by beginners, and one of their many troubles is to find quickly information upon which reliance may be placed. Authors thoroughly conversant with all the multitudinous details of their subjects are apt to take it for granted that the readers for whom they are writing are equally skilled in the rudiments, and the result is that what are elementary points to the experienced are omitted. It is particularly these that the tyro wants to aid him to establish his garden on a sound foundation. Far be it from me to blame the authors, since I have the honour to take humble rank with them, and have probably found as many pitfalls as the majority—very possibly more than the minority—and, so doing, have failed in some degree of my duty.

The author of "Fruit-Growing for Beginners," Mr. F. W. Harvey, F.R.H.S., Editor of *THE GARDEN*, has made no mistakes in the direction indicated, because he has taken nothing for granted. It is true that he wanders into error in the second and third lines of his Preface, when saying that there is no handbook on fruit culture suited to the

needs of the amateur. Filial duty, with honesty of opinion, compels me to say that "Profitable Fruit-Growing" is essentially a book for the novice, and my father's name will be honoured by posterity as its author. But, after all, it matters little what is said in a preface, since no one reads it other than the one who is anxious to find fault or to seek an excuse to grumble about a point which has no practical importance.

Mr. Harvey, then, sets himself to teach the principles which underlie successful fruit culture, and he admirably succeeds in his task. He has achieved the distinction of getting right down to his subject, with the result that no detail has been passed over as too insignificant for statement. He has fully appreciated the fact that the grower who has once learned the small points has set his feet firmly on the threshold of success. Too many amateurs who become imbued with the love of gardening rush ahead without thought or consideration, and, later, wonder why failure has been the end of their efforts. The best advice that I can give those who are about to essay the art of fruit-growing is diligently, intelligently and repeatedly to study Mr. Harvey's simple words of wisdom, because their reward, provided, of course, that they proceed with scrupulous exactitude mixed with the common-sense with which they are endowed, must be gratifying success. The man who could fail under such instructions as are given in this book would, indeed, be clever in his stupidity, so clearly and forcibly are the fundamental principles set forth in its 124 pages.

"Fruit-Growing for Beginners" resembles other books in that it is arranged in chapters, each treating of some particular phase of its subject; but it differs from many, probably from most, in having a tail to every chapter, in which its burning point—might I say its sting?—is summarised. For example, who will venture to dispute the truth of any one of the following facts or statements? "Grow your own fruit. It will be better than any you can buy. Nurserymen will be pleased to supply trees for large or small gardens. The beginner should not attempt at the outset, before he has gained some practical knowledge, to grow fruit on a large scale. Start with a few kinds and master the cultivation of these first."

There are exhaustive chapters on soils, sites, propagation, forms of trees, planting, staking, pruning, mulching and manuring, all dealing with generalities; while subsequent chapters treat specifically of Apples, Pears, Plums, Cherries, Peaches, Nectarines, Apricots, Gooseberries, Currants, Blackberries, Raspberries, Logan and kindred berries, Figs, Medlars, Quinces, Mulberries, Grapes and Nuts, so it is abundantly clear that nothing has been omitted. Beyond these there is a chapter on the insect pests and fungus diseases to which the fruit trees of our gardens are heirs. This is so important a phase of the subject that it might have been amplified to advantage. Severe compression has forced the omission of such remedies for American blight as the application of linseed or sweet oil, and of Hellebore powder against the Gooseberry caterpillar. But perhaps these criticisms are a little captious. Throughout the whole of the 124 pages which comprise "Fruit-Growing for Beginners" there is sound advice, which might be followed with much benefit by many old as well as young growers. The several illustrations are on all fours with the letterpress—practical instructive value has been allowed to overwhelm mere ornamentation. — HORACE J. WRIGHT.

* "Fruit-Growing for Beginners," by F. W. Harvey, F.R.H.S.; price 1s. or in stout cloth covers 1s. 6d. net. The County Lib. Library, 20, Tavistock Street, Covent Garden, London, W.C.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Office: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Our Sweet Pea Number.—Our next issue, dated February 1, will contain a number of special articles on Sweet Peas, and these will deal with several little-understood phases of Sweet Pea cultivation. There will also be included a coloured plate of four of the best Sweet Peas of to-day and some unique photographic illustrations of Sweet Peas. As there is sure to be a large demand for this issue, we advise readers to order in advance any extra copies they may require. The price will, as usual, be one penny.

Tulip Vermilion Brilliant.—It is difficult to understand why this Tulip is not more extensively grown in pots for forcing into flower early in the year. Compared with the Duc Van Thol varieties, which appear to find so much favour, it has much to commend it. The flowers are of deep rich colour, are borne on long stems, and last in good condition for a much longer period than the Duc Van Thols. Although its habit is rather stiff, this is not noticeable when the plants are arranged with a few small Ferns or other foliage plants.

An Annual for a Sunny Spot.—Now that seeds of annuals are being ordered, it may be useful to draw attention to the Sun Plant, *Portulaca grandiflora*, which is an ideal, low-growing flower for the hottest place in the garden. It delights in well-drained, rather sandy soil, and seeds are best sown towards the end of April or early in May where the plants are to flower. There are single and double flowered forms, and both are usually sold in mixed colours, some of which are very brilliant. The plants are quite procumbent, have fleshy leaves and quickly form a carpet.

A Little-Known Dianthus.—There is a charming little Mountain Pink known as *Dianthus microlepis*, which is seldom seen in gardens and rarely mentioned in horticultural works. The flowers are carmine red and the plants dwarf and tufted, not unlike *D. glacialis* in miniature, although it is quite distinct from that species. It occurs in the mountains of Thrace and Bulgaria at fairly high altitudes. There is also a white form, but this is seldom found in the wild state. When better known, *D. microlepis* bids fair to become a popular alpine plant.

A Useful Winter Shrub.—One of the most interesting shrubs during the winter months, and one that is not sufficiently grown, is *Cassia fulvida*. At the present time its golden leaves, minute though they are, make quite a warm and pleasing feature in otherwise dull surroundings. It is a quick-growing and rather ungainly shrub, but this defect can be remedied by occasionally pruning back the too venturesome growths in March. Anything like formality must, however, be carefully guarded against when pruning. This shrub was at one time known as *Diphappus chrysophyllus*.

A Valuable Timber Tree. It is not generally known that *Catalpa cordifolia* (which is sometimes regarded as a vigorous form of *C. bignonioides*, or Indian Bean Tree) is valued by reason of its wood having the remarkable power of resisting decay when in contact with earth or water. The following observation is made by Sargent: "The trunks of Catalpa trees killed by the sinking and subsequent immersion of a large tract of land near New Madrid, Missouri, which followed the earthquake of 1811, were standing perfectly sound 67 years later, although all their companions in the forest had disappeared long before." Catalpa wood is well adapted for railway sleepers, gateposts, &c., but so far Catalpas have only been grown in this country as ornamental flowering trees.

A Beautiful Heath.—An interesting group is formed in the greenhouse at Kew by several kinds of *Ericas* and various Australian shrubby plants, but *E. melanthera* is the most conspicuous subject, for it is represented by specimens $3\frac{1}{2}$ feet to $4\frac{1}{2}$ feet high, which are flowering from base to summit. Grown in a different way to that usually adopted for *Ericas*, they have been allowed to attain their present height practically unchecked; thus they are very narrow in comparison to their height, the side growths nowhere being more than from 6 inches to 9 inches in length.

The Rev. W. Wilks.—We are pleased to be able to announce that a movement is on foot to present a testimonial to the Rev. W. Wilks, secretary of the Royal Horticultural Society, as an appreciation of his services to horticulture during the past twenty-five years. As we pointed out in our issue for December 28, 1912, Mr. Wilks has been secretary of the society for that period, and during that time has done a vast amount of good work for the society and horticulture generally. Subscriptions towards the testimonial are invited from Fellows of the society, such subscriptions not to exceed £1 1s. All cheques and postal orders should be sent to the Manager, the London County and Westminster Bank, Victoria Branch, Victoria Street, Westminster, and should be crossed "Wilks Testimonial."

The Purple-Leaved Plum.—It is usual for this tree to blossom towards the end of March, but this year many flowers were open during the first week in January, thus making a companion for the early-flowering Almond, *Prunus davidiana*, which often opens its flowers towards the end of January or early in February. Both these trees require planting against a background of Pines, Arbutuses, Evergreen Oaks, or some other evergreen to be seen to advantage, otherwise much of the effect is lost. A group of the Purple-leaved Plum was noted recently near a cluster of Pine trees in the Arboretum at Kew, and the effect of the white flowers and dark foliage was very pretty. An undergrowth of variegated-leaved Dogwood makes this particular group attractive during summer also.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

An Old Oak at Hampage Wood.—I am enclosing a photograph of an old Oak, called the "Gospel Oak," which stands in Hampage Wood, near Avington Park, Aresford, Hants. Local tradition supposes St. Augustine to have preached the Gospel under it, and this legend would seem to be supported by the story of Bishop Walkelin sparing the Oak when he felled the whole of the remaining timber in Hampage Wood for the rebuilding of Winchester Cathedral in the year 1079.—E. G. S. [Unfortunately, the photograph sent by our correspondent was not sharp enough for reproduction.—Ed.]

A Delightful Nettle Iris.—At the time of writing (January 16) the charming variety of Iris reticulata known as histrioides is in full bloom. The flowers are deep blue in colour and a shade deeper, almost purple, in the falls, with cream markings radiating from a golden line running down the centre. Since the flowers are produced in little tufts near to the ground, it seems to suggest that it would be an admirable subject for intermingling with yellow Crocuses now coming into bloom. It is one of the daintiest of January flowers, showing a preference for a light soil and sheltered position.—Q., Surrey.

The Sweet-Scented Verbena.—The valuable article by Mr. E. Beckett on "The Best Shrubs for Low Walls," on page 15, January 1 issue, mentions the old Sweet-scented Verbena, Aloysia or Lippia citriodora. Mr. Beckett justly says that this is well worth a position on a wall, giving shelter from hard frosts in winter. Even in Scotland, though in the milder parts, it will stand the winter fairly well on a wall; but it is greatly helped by having a glass coping over it—a valuable protection for many tender subjects. Where glass accommodation is limited, it is an advantage to know that the Sweet-scented Verbena can be grown on a wall.—S. ARNOTT.

Daisies Flowering in Scotland.

I send you some Daisy plants in full bloom. They have now been blooming here fully two months all over our lawn, in spite of very severe frosts at times during this period and some snow. We stand very high on a hill on the northern bank of the river Tweed, and are much exposed to northerly, westerly and southerly winds. Our gardener thinks, with me, that this blooming of Daisies thus far North at such a time of year may be of sufficient interest for you to mention it in THE GARDEN.—(Mrs.) F. M. J. BAXENDALE, Bemersyde, St. Boswells, N.B. [The plants sent by our correspondent were flowering very freely. This is not unusual in the Southern Counties of England.—Ed.]

Rose Sarah Bernhardt.—I am glad your worthy correspondent "Hancroft," on page 30, issue January 18, finds some of my notes on the newer Roses amusing. I could hardly expect that he would find them instructive also. He does not consider I am justified in stating that the trade has overlooked this Rose, and in order to prove they have not he states that he knows as a fact that two well-known firms have listed it since 1908, and that he himself has exhibited it for the last four seasons. A gross total of three nurseries! To which I can only reply, But what are they among so many? My statement was not founded on catalogue knowledge. Since 1906, when I think Sarah Bernhardt was introduced

Cyclamen corms for many years, and have at the present time a nice batch of plants in flower. Some of them are fourteen years old, and annually produce eighty to a hundred flowers on each plant. The corms should be carefully ripened after flowering, as I think next season's display depends on this. They should not be shaken out or repotted until the corms break into new growth. Then they should be carefully cleared of decayed stalks and potted into smaller pots than those in which they last flowered. Do not throw them aside like an old broom after they have given you so much pleasure. Treat them kindly, and they will repay you for all your trouble.—WILLIAM DRIVER, Stonehouse, Gloucestershire.

—In your last issue, page 29, you have a note as to the age of some corms of Cyclamen persicum, and mention one plant which you know to be of the age of twenty-five years, asking if this can be beaten. I do not know about C. persicum, but there is a corm of C. neapolitanum in this garden, brought here by my late father, which must be at least forty years old, and which still annually bears a profusion of flowers. I measured it last autumn, and it is about eight inches in diameter.—F. HERBERT CHAPMAN, Rye.

A National Daffodil Society.

I was very glad to read a letter on the above subject in your issue of the 4th inst., page 2. The formation of such a society, it seems to me, has been too long delayed, and should not be further postponed, for the Daffodil and its cult is developing with remarkable rapidity, and in the interests of the trade and lovers of the flower alike it is most desirable that a society should be formed to look after its many interests, just as the Rose, Sweet Pea and other societies have been formed for a like purpose, and with excellent results. In your issue of February 18, 1911, pages 74 and 75, you were good enough to publish a letter of mine on this subject, and from conversations I have since had with those interested in the Daffodil, I am convinced that such a society has but to be started under good auspices to be successful. But in this, as in all else, it is a case of "It is the duty of leaders to lead"! Will not those many well-known heads

A BEAUTIFUL DWARF EARLY FLOWER, IRIS RETICULATA HISTRIOIDES, PHOTOGRAPHED OUTDOORS ON JANUARY 16.

(not 1908) I have visited scores of Rose nurseries, and I only remember finding Sarah Bernhardt in one of them. I am truly sorry if I have hurt the feelings of anyone in the trade; but I submit for a Rose introduced in 1906 to have to wait until 1912 before it finds its way into such recognition as three catalogues would give it, surely justifies my statement that it has been overlooked. But we are both agreed that Sarah Bernhardt is a good Rose that should be more grown.—HERBERT E. MOLYNEUX.

Old Cyclamen Plants.—I agree with you about the longevity of Cyclamens. I have grown old

of the Daffodil world put their shoulders to the wheel? If they will but do for the Daffodil what Rose-growers and Rose-lovers have done and do for the Rose, I feel positive that the "small fry," of whom I am glad to count myself one, will heartily back them up. There are many, I know, who feel, as I do, that the Daffodil is too important a flower to be run as a "side-show," even by so excellent and powerful an institution as the Royal Horticultural Society. A "Conference of the Powers" could easily be arranged if only one of the "big-wigs" would take the necessary steps. Who will carry the flag?—A. C. CARNE ROSS, Brecon.

Iris tingitana Flowering Outdoors.—It may be of interest to your readers to know that I picked on the 8th inst. in the open a bloom of *Iris tingitana*. I have two other buds showing colour. This is quite the earliest date on which I have seen this iris in flower.—H. G. HAWKER, *Strode, Ivybridge*.

Omphalodes verna Flowering in December. Among the lists of plants given as flowering especially early this winter, I have noticed no mention of *Omphalodes verna*, a plant of which I saw in full bloom in a garden near here on December 27, 1912, growing in a shaded border with a western aspect—MAUD CLYNE, *Albury Hall, Much Hadham, Herts.*

Malmaison Carnations.—The article by Mr. Allardice on these Carnations, page 651, issue December 28, Vol. LXXVI., had three most interesting and instructive points: (1) the unusual layering material employed; (2) his saline preparation for improving the foliage; and (3) the pinching or stopping back system adopted. It has been my lot to work in two very large establishments where some hundreds were yearly managed, but in neither did we practise points one and two, though point three was most successfully followed by one of the gardens. From personal observations and enquiries made, I am inclined to believe very few gardeners have ever tried the experiment.—C. T.

Iris stylosa.—I have picked fully ninety blooms from my two small clumps since November, and there are plenty more to come. I am rather surprised, because last summer was a wet one; but I think the three hot weeks in July effected the necessary ripening of the plants, which are close up to the wall of the house facing west, where they have been for seven years. I never divide or move them; I keep them as dry as possible; I never manure them; I just leave them alone. I think May and June are the months to make a fresh planting. No flowers must be expected for the first year after planting or moving.—H. W. PRICE, *Amblecote, Cobham, Surrey.*

Viola florairensis.—The note by M. Correyon on *Viola florairensis*, page 11, January 4 issue, should be welcomed as drawing notice to one of the prettiest and most useful of the small alpine Violas. I first saw it last summer in the wonderful rock garden of Sir Frank Crisp at Friar Park, Henley, and was much pleased with its beauty there. Mr. Knowles, who has a thorough knowledge of the plants under his charge, had a very high opinion of *V. florairensis*. It seems to have a good deal of the character of one of the parents, *V. rothomagensis*, but improved by the influence of *V. calcarata*. As a rock garden plant *V. florairensis* is much superior to many of the other hybrids we see and hear so much about.—S. ARNOTT

The Manetti Stock for Roses.—Just now is what one may term the holiday season for the Rose-grower and at such times he is open to discuss matters that, if mooted during the summer, would probably be allowed to pass unchallenged. I must confess I have been a strong opponent of the Manetti stock, but I think, in justice to an old friend, one must give it its due. In November last I saw a grand bed of Richmond almost in full bloom. The plants were only planted in the previous autumn, but they were evidently quite happy and growing luxuriantly in a deep soil of a strong clayey nature. Now, these plants were on the Manetti! It was not the first occasion I had noticed the superiority of this variety when grown upon the Manetti. As a maiden I have had superb flowers of Richmond from the Manetti. Another Rose equally grand as a maiden on Manetti is

Lady Ashton. Last summer I thought I would try some of Messrs. A. Dickson's fine novelty, Mrs. Walter Fawcett, on the Manetti, as upon the seedling Briar the growth did not satisfy me. I was rewarded freely with splendid plants, and by dis-budding freely splendid show blooms resulted. This is no news to the Rose man, but he will say, "How about the Manetti for cut-back plants?" This is what I want to ascertain. Have any readers found any special sorts superior as cut-backs on Manetti stock? If so, they would be rendering rosarians some service if they would name the sorts and the soil they were growing in. This question of stocks is a very important one, and I wish the National Rose Society, when they issue their new official catalogue, would give us some reliable expert opinions upon the best stock for each variety.—DANIEL CROFT

FORTHCOMING EVENTS.

January 28—Royal Institute Meeting. Lecture by Professor W. Bateson.

January 31—Beckenham Horticultural Society's Meeting and Lecture.

February 1—Société Française d'Horticulture de Londres Meeting.

GARDENING ACROSTICS.

As announced in our issue for December 14, 1912, we are publishing a series of eight acrostics based on gardening or simple botany. Prizes of £3, £2 and £1, respectively, will be awarded to those sending in correct solutions of all the acrostics. The names of those who have correctly solved the problems will be published from week to week, and the final list of prize-winners in our issue of February 15. In all cases the Editor's decision must be final. The solution to Acrostic No. 6, which appeared last week, will be published next week, and the solution to No. 7, which is printed below, will be published in our issue dated February 8. For full rules governing the competition readers are referred to page 623 of our issue for December 14, 1912.

DOUBLE ACROSTIC No. 7.

Written about by Andrews; grown by the Loddiges; sometimes in favour, sometimes not. Grown indoors and out of doors.

My firsts are my English name, and my lasts that given me by Phny.

1. Sometimes a "Rose," sometimes a "bear's foot."
2. A method of training fruit trees.
3. As good as Ivy and cleaner.
4. Frequently put into pots. Best when turned over as I must be.
5. Mahomet's Flower of Paradise.

Solutions of the above must be sent so as to reach the Editor at 20, Tavistock Street, Covent Garden, London, W.C., not later than February 1. Mark the envelope "Acrostic" on the upper left-hand corner.

SOLVER OF ACROSTIC No. 4.

ONLY one competitor correctly solved Acrostic No. 4. This was the Rev. J. E. Gardner. We would remind readers that in the event of no one correctly solving all the acrostics, the prizes will be awarded to those who send in correct solutions of the greatest number.

* * * The names of those who have correctly solved No. 5 will be given next week.

SOLUTION AND NOTES OF ACROSTIC No. 5.

* Malpighi, an Italian, and Grew, an Englishman, both of whom lived in the latter half of the seventeenth century, are styled "co-founders of the science of Plant Anatomy."—See "Makers of British Botany," page 44. † Orange trees were very highly esteemed 200 to 300 years ago.—See "Systema Horticulturae," by Woodrudge (Woodrudge), fourth edition, page 138. An Orange tree was a "Green." ‡ Rapin, a French Jesuit, wrote a Latin poem on Gardens in four parts, Flowers, Trees, Water and Orchards. This was translated into English by James Gardner in 1718. § London in his Encyclopedia (fourth edition, page 710), quotes Martyn as suggesting the derivation of Apricot from "a Procox," then with usage "Apricocks"—now Apricots. It was once looked upon as an early Peach. "Seed of the Sun" is a Persian name, and one can easily see its appropriateness. ¶ Botanists have now agreed that "n" should be used in terminations. * For some of the aliases of Nigella (a diminutive of niger, black) see "Annual and Biennial Garden Plants," by A. E. Speer. The seeds are small and black. ** Emmerton was a famous grower of Auriculas, and wrote a treatise on them, which was published in 1816. †† For the "Doctrine of Signatures" see Agnes Arber's "Herbals," Chapter VIII. Such names as Adder's Tongue, Eyebright, Lungwort and Liverwort have been given for the medicinal properties the plants were said to have. Why they should have such names is explained by their "Signatures."

PRIZES FOR THE BEST ROCK GARDENS.

To further stimulate the interest that is being taken in rock gardens, the Proprietors of THE GARDEN offer the following prizes for three photographs of a rock garden, or portions of a rock garden:

First prize: Five Guineas, or a Silver Cup of that value.

Second prize: Two Guineas, or Books of that value.

Third prize: One Guinea.

The competition is open only to the actual owner of the rock garden, or to his or her gardener. The object is to encourage good rock gardening, and preference will, therefore, be given to those rock gardens which show originality in design, and where the plants depicted are well grown. It should be distinctly understood that awards will be made to the best rock gardens, and not necessarily to the best photographs. The photographs need not be taken by the competitor, who must, however, in such cases have the written consent of the photographer for their reproduction in THE GARDEN. For rules governing this competition see issues for January 4 and 11.

SCIENCE IN RELATION TO HORTICULTURE.

DURING recent years science has played a very important part in the progress of horticulture, and we propose to publish from time to time, under the above heading, particulars of recent scientific investigations. These articles will be written by Mr. D. Houston, F.L.S., Agricultural Biologist at the Royal College of Science for Ireland. Mr. Houston has for many years been keenly interested in science as applied to horticulture, and is able to write about it so that the average reader can understand what is meant.

Rust in Hollyhocks.—Professor Eriksson, a Swedish botanist, has been investigating the life-history of the parasitic fungus that causes "rust" in Hollyhocks and Mallows (*Phoma Malvacearum*). The disease is a very troublesome one to gardeners, so much so, indeed, that the culture of Hollyhocks is not even attempted in some gardens. The disease came originally from South America, from which it spread to "the States" and to Europe. Everyone knows the disease, and that the rust patches represent little ruptures in the skin of the host plant filled with the spores technically known as "teliospores." In most cases, in other plants where teliospores are formed they hibernate during the winter, but in the present case they can germinate at once, and so propagate the disease during the whole of the growing season. This is one reason why the disease spreads so rapidly. According to Eriksson, the spores cannot survive the Swedish winters, neither can the vegetative mycelium of the fungus existing in the plant. How is the disease propagated, then, from season to season? Eriksson says that the source of infection is from the seeds. His belief is that the living matter of the parasite mixes with the living matter contained in the cells of the Hollyhock, and that when the seeds are harvested the parasite is dormant in the seeds. As the seeds germinate in the spring, the fungus also awakens into life, and when the plants reach the age of three months the mycelium of the pest invades every organ of its body and breaks out into rusty eruptions all over the plant. It should be added that this idea of Eriksson's is not universally accepted by working botanists, as a belief is held by some that the surface of the seeds gets contaminated with the microscopic spores, much in the same way as seed grains get contaminated with the spores of smut. In any case, it is clear that gardeners should pay close attention to the origin and character of the seeds of all malvaceous plants before they venture on sowing them.

Explosives as an Aid to Gardeners.—The use of explosives as helpful agents in laborious tillage

operations is at present engaging the attention of cultivators. Cartridges containing a comparatively safe explosive are inserted at suitable depths in the soil to be disturbed, with the result that after the explosion the deep subsoil is cracked and fissured, and the upper soil reduced to powder through the sheer violence of the shock. Experiments, for example, have been successfully carried out in heavy, wet soils expensive to work under ordinary methods of cultivation. The work was most effectively done and at a relatively low cost. The advantages claimed for the method are: 1. It so displaces the soil that it alters its physical character, rendering it more suitable for the roots of cultivated plants. 2. By fusing the soil it

strong enough, while gun-cotton and dynamite are too dangerous. The "safety" type contains at least 80 per cent. of nitrate of ammonia, and being in itself a valuable plant food, it contributes to the fertility of the soil.

Feeding Carnations.—An interesting series of experiments with artificial fertilisers in relation to Carnation culture has been carried out recently at the New Hampshire Agricultural Station. Recognising the commercial interests involved in the cut-flower trade, the objects of the experimenter (D. Lunsden) were, first, to discover the relative value of certain fertilisers applied as a top-dressing to Carnation plants grown under glass, and, secondly, to determine if differences in manurial treatment affect to any appreciable extent the keeping quality of the cut blooms. It will be unnecessary to describe the experiments at length, but the tests were carefully arranged and strictly carried out. The fertilisers used were (among others) bone-meal, nitrate of soda, muriate of potash, fowl-manure and Clay's Fertilizer. The bone-meal gave the best results. Its action was much slower than that of the nitrate, but the plants were more vigorous and the keeping properties of the cut flowers markedly superior to any of the other manures used. Clay's Fertilizer was the second best with respect to keeping quality. It was quicker in action than the bone-meal. Fowl-manure, when used in small quantities, came third, but used in excess was distinctly harmful, as it induced a rapid but weak growth and greatly shortened the keeping period of the cut flowers. Muriate of potash produced good-keeping blooms, but it was not nearly so good on the whole as the three already named. Nitrate of soda produced the least satisfactory results. The plants responded very quickly at first, but eventually they showed less vigour, and the cut flowers lost their freshness much sooner than the others. D. HOUSTON

ROSE MRS. MACKELLAR, A NEW HYBRID TEA OF GREAT PROMISE.

ROSE GARDEN.

ROSE MRS. MACKELLAR.

This charming Hybrid Tea bids fair to become popular when better known. In colour it is of a creamy yellow tone, possessing the precious gift of fragrance. It carries a large bloom of good substance, the form of which is clearly depicted in the accompanying illustration. It is one of many superb varieties for which we have to thank Messrs. Alex. Dickson and Sons, Limited, Newtownards, County Down, and was shown in September last before the Royal Horticultural Society with two other new Roses, viz., George Dickson and Edward Bohane, each of them being honoured with an award of merit. The Rose under notice is named after the wife of Mr. A. Mackellar, V.M.H., the well-known head-gardener at the Royal Gardens, Windsor.

materially increases its water-holding powers. 3. In the case of wet lands it improves the drainage by forming deep fissures in the subsoil. 4. In the work of planting fruit trees, holes can be rapidly formed and the upper soil and subsoil considerably improved as a medium for root development. In old orchards also the soil can be opened and improved. 5. Other work, such as the excavation of ditches, can be easily carried out by the explosive method. The kind of explosive recommended is a safety one, having as its base the nitrate of ammonia made by the Favier Explosives Company of Vilvorde, near Brussels. Gunpowder is not

SOME OF THE NEWER DECORATIVE ROSES.

(Continued from page 32.)

Dorothy Ratcliffe (S. McGredy and Son, 1911), Hybrid Tea—One of the first of the British-raised Roses to have as one of its parents one of the pernetiana Roses; and the first, one has little doubt, of a large army that will vary and be of all colours possible to Roses. Here we have a slight resemblance to Lyon Rose, but the plant is a better shape and a better grower, and has not the bad habit of defoliation that spoils Lyon Rose as a bedder. The flowers are of good shape; colour variable, coral red, shading to tawn yellow as the flower ages. It received the silver-gilt medal of the National Rose Society at the autumn show in 1910, and should be extensively planted by those who like the Lyon colouring, but do not like its "manners and customs."

Ethel Malcolm (S. McGredy and Son, 1910), Hybrid Tea.—A good garden Rose and fragrant; fully described under "Exhibition Varieties."

Evelyn Dautesey (S. McGredy and Son, 1911), Hybrid Tea—I was very pleased with this Rose in my garden last year. Notwithstanding the wet of the autumn, it opened well and freely. It is quite a good grower, of excellent habit; colour, soft salmon, outside of petal a deep carmine rose, and the flowers were freely and continuously produced; delightfully fragrant. As a bedder I can strongly recommend it, as the colour is warm and distinct. One hesitates to call it an improvement on La France, but it is reminiscent of that grand old variety, and certainly does not ball in damp, wet weather. The flowers come with a good point, and the petals reflex like La France, but are much deeper in colour, more like Grand Due A. de Luxembourg. It was the first Rose to receive the silver-gilt medal of the National Rose Society, awarded for the first time at the "National" at Regent's Park in 1910, and I hope all silver-gilt medal Roses will equally well deserve the award as Evelyn Dautesey has proved she did. I see the last "e" is generally left out, but I have ascertained that as printed at the head of this note is the correct way of spelling the name.

Eugene Boulet (Pernet-Ducher, 1910), Hybrid Tea.—I should say an Etoile de France seedling with a little more crimson in the flower. It opens (as well it might) very much better than that disappointing Rose, is a good grower, and very free-flowering all through the season. A crimson red, with a certain amount of purple in the older flowers. One of those Roses that will not be wanted for long, as it is bound to be improved upon as far as colour goes.

Ferniehurst (Alex. Dickson and Sons, 1911), Hybrid Tea.—A garden Rose of much promise as well as an exhibition variety, under which heading I have already described it.

Florence Haswell Veitch (William Paul, 1911), Hybrid Tea.—A Rose that has been very strongly recommended to me as a splendid garden Rose, of good colour and very fragrant. It is vigorous

enough in growth to be called almost semi-climbing, good scarlet, and likely to be very useful. I have not flowered it, so am only passing on information which I, however, believe to be reliable.

George Reimers (Souper et Notting, 1910), Hybrid Tea—A good-coloured scarlet that will be useful, though for a short time only. A fine grower and bedder, not a bad shape, with a good long bud. I am afraid the life of many of our new Roses will be very short, here to-day and gone to-morrow. The progress that is being made is so rapid that they will be quickly superseded.

Herzogin Marie Antoinette (Jacobs, 1911), Hybrid Tea—This was one of the best of the Continental varieties that I tried in 1912. I did not see it in any of the nurseries I visited, and the only catalogue I have been able to find it in is that of Messrs. Alex. Dickson and Sons. It is undoubtedly a lot better than many others that are being grown

ROCK AND WATER GARDEN.

THE MOUNTAIN AVENS.

(*DRYAS OCTOPETALA*)

THIS beautiful plant is, unfortunately, not too generous with its creamy, Rose-like flowers when growing in our gardens, no matter how carefully we humour it. In the mountains, however, it is one of the most universal of alpine plants, and seems equally happy on either limestone or granitic formations, provided it has full exposure to sunshine and root moisture during its growing season. At elevations ranging from 5,000 feet to 7,500 feet this Mountain Avens makes glorious, spreading patches of verdure many feet across, which in June and July become sheeted with the pale cream, eight-petalled flowers rising

THE MOUNTAIN AVENS (*DRYAS OCTOPETALA*) IN ITS NATIVE HAUNTS ABOVE ZERMATT.

and catalogued. It only for its colour it is worth a place. I heard of it from a Continental correspondent, and he thought very highly of it and told me it had received quite a number of awards. It is a yellow of a good deep shade generally called orange, fading to an old gold. It is very fragrant, with strong Tea perfume, and a good grower. Reminiscent of Marquise de Sinety at its best.

James Ferguson (William Ferguson, 1911), Hybrid Tea.—A Scotch-raised sport from Caroline Testout, of a beautiful silvery pink shade; identical in every other respect. It was awarded a silver-gilt medal at the National Rose Society's autumn show at Vincent Square in 1910. It is certainly a lovely colour, paler than Mme. C. Juranville, and the only other sport of Caroline Testout that I think worth growing.

Jonkheer J. L. Mock (Leenders, 1910)—See "Exhibition Varieties."
Southampton. HERBERT E. MOLYNEUX

just above the foliage. So plentifully are these yellow-eyed, Rose-like blossoms produced that the foliage is often in danger of being overlooked. When above Zermatt during July last I came upon whole hillsides clothed with this lovely plant, mingling on the sloping banks with *Primula farinosa*, *Soldanella montana* and *Pinguicula*. Here, though the chief flush of the flowering season was past, I secured the accompanying photograph, which gives some idea of how decorative a plant the *Dryas* can be when well flowered. From observations in the mountains I believe success would more surely attend our efforts in the lowland garden if we gave it the same extremely gritty, well-drained soil and sunny aspect in which it thrives in its native habitat, and also ample water from March to July. Possibly it would make a satisfactory moraine plant, since that situation would provide these various requirements in a large degree.
REGINALD A. MAIBY.

A RARE PRIMROSE.

(PRIMULA JURIBELLA)

FARNEST enquiries have often sought of me the character and country of this very rare Primula. In the innocence of my heart I myself once derived its name mysteriously from "Jura," and believed it the especial species of that range. It was only quite by chance one day that in scanning a map of the Dolomites I came upon the word "Gaur-bella," and instantly knew that my quest was ended. P. Juribella, in fact, takes its name from the Gaur-bella Alp (where, to the best of my belief, it does not

Unfortunately, this and some of the other hybrids with minima for one parent come up disastrously for comparison against such crashing beauties as minima itself, or gorgeous spectabals, blazing tyrolensis, bland and melting Allionii, or the imperial violet loveliness of glutinosa. Few indeed of the hybrid Primulas can hope to rival the beauty of their progenitors. There is no question about floerkeana, Kellereri, Forsteri and Heeri; but if Juribella had ambitions to do so, it has not succeeded. I will only add that in the garden P. Juribella, like almost all the other hybrids,

and a stock raised of the rose or pink coloured varieties from cuttings, which are readily rooted under a bell-glass or hand-light in a half-shaded spot in the garden, when they should then be planted out direct into their permanent positions for flowering, as they are impatient of any interference with the roots when once they have reached their flowering size. The habit of the plant is that of a free-branching dwarf shrub, and, densely clothed with rich green or slightly glaucous leaves in all the upper parts of the stems, the flowers appear in July and continue in good condition until the end of August, while odd flowers continue to appear until October, with its accompanying frosts, checks all further display. From its freedom of bloom and branching habit it should make a valuable parent, especially if crossed with the Carnation or Pink; at any rate, I throw out the suggestion for what it is worth.

The plants depicted in the accompanying illustration were three and a-half years old from cuttings, and were each over four feet in height and about five feet in diameter in July. Under favourable conditions, such as obtain in the South-West of England and Ireland and on the South-West Coast of Scotland, the species would require little or no protection, and would rapidly form a large bush. It is a native of the Grecian Archipelago, also of the island of Crete, and is well figured in Sibthorp's "Flora Græca," t. 406. C. P. RAFFILL.

THE TREE PINK (DIANTHUS ARBOREUS) IN THE ROYAL GARDENS, KEW

grow), above the Val Fravignolo in the Pala Dolomites, and is a hybrid (only, I believe, recorded here) between P. minima and P. tyrolensis. To know all this was to go there. The first year I had trouble in finding the hybrid, for the flowers were quite passed; but find it I did, and abundantly, on one little steep slope of a mountain whose turf was full of P. minima, and its limestone rocks with P. tyrolensis. Once seen, the leaf is never forgotten. Growing among P. minima it is much rounder, drays to an oval and is not glossy, but dull green, with glands that are its legacy from the extreme stickiness of P. tyrolensis. This season I went out again to see it in bloom; but the flower, I must confess it, disappointed me. There is a vindictive aniline note about P. tyrolensis which is so brilliant as to end by being impressive. To the hybrid, however, it gives a tone that is at once loud and feeble in its vulgarity. Then, having inherited the worst fault of its father, P. Juribella adds to it the thin and ragged outline that is the worst fault of the worst forms of minima, its mother. I am measuring P. Juribella, of course, by a very exacting test. In itself it is certainly a very bright, striking and splendid little plant.

seems to show, as a rule, much more vigour and robustness than either parent under ordinary conditions of reasonable culture. REGINALD FARRER.

THE FLOWER GARDEN.

THE TREE PINK.

(DIANTHUS ARBOREUS.)

WHAT is probably the giant of the genus is the subject of the accompanying illustration. It has long been in cultivation, but has not met with the appreciation it deserves, this being probably due to the fact that it is somewhat tender, requiring to be given a warm, sheltered spot, such as the foot of a south wall, and to be protected during severe weather. A well-grown specimen in full flower is really a charming sight, as the flowers open in succession for a period of six or eight weeks. These are 1½ inches in diameter and variable in colour, from pink and rose to lilac, the lilac shades predominating among the plants raised from seeds. These had better be discarded

as the Lilies. The soft greyish blue of the Ceanothus was delightful as contrasted with the colouring of the Lily. Apricots stirred up with plenty of cream comes nearest to its colour of anything I know, for I never remember to have seen the Indian heroes of old who walked forth in nankeen breeches.

It evidently likes us, for the group in question began as six bulbs, and at every lifting since they have increased in a most satisfactory manner. They have had no special luxuries provided for them, but just the ordinary border soil, enriched, at the rare intervals when the border is turned out and replanted, with farmyard manure. For all its delicate beauty this Lily does not seem to object to a little strong feeding, provided the bulbs do not actually come into contact with the manure.

Its origin is wrapped in mystery. Some think it came from Japan, and Dr. Wallace stated, in his useful book, "Notes on Lilies," that he had "more than once" seen Japanese drawings by some of the best artists in Yeddo which strongly resembled it. Mr. Elwes, in the great "Lily Monograph," declares, on the contrary, that no such plant is represented among the Japanese drawings seen by

lum. A recent work on Lilies, given 1849 as the date of its first recorded appearance, I think following a misprint in Dr. Wallace's book, for it was described by Lindley in the *Botanical Register* in 1842 as flowering in Rollison's Nursery at Tooting, and was figured in the following volume—that for 1843. It is there said to be of Japanese origin, and a frame or half-hardy bulb. But the best account of its appearance in Europe is that given by M. Van Houtte in Vol. I. of the "Flore des Serres." He tells how M. Haage of Erfurt found it, about the year 1836, in a bed of Martagons which had been sent to him from Holland, and that it was also in the possession of three amateurs at Lille, who each believed his the only stock of it. M. Van Houtte saw it in one of their gardens and greatly admired it, and not long after a quantity of bulbs were offered him from yet another source. All this appears to point to its origin as seedlings from an accidental crossing and the dissemination of the bulbs before they had flowered. This would accord with the generally-accepted opinion that it is a hybrid between the Madonna Lily, *L. candidum*, and the scarlet Turk's-cap, *L. chalcidonicum*. Its colour certainly suggests this combination. Having no wild home from which collected bulbs can be torn, we are dependent on nursery increase for its supply, and that I take to be the reason of its still rather high price; but then, on the other hand, one is sure of getting home-grown bulbs. So I strongly advise its purchase and planting in as great numbers as the plumpness of one's purse admits. It certainly looks best in large groups, and is equally good at the back of a border among quiet, cool-coloured neighbours, or standing out at the corner of a bed among dwarf plants. Dandy Sadler has so placed it in one of his charming pictures, but I fear by the costumes of the dear old couple sitting by it he has antedated its introduction to English gardens.

The Madonna Lily, *L. candidum*, is so well known that it seems a work of supererogation for me to write of it. But I do not think it is so generally appreciated as the fact deserves that there exists a poorer form of it called var. *peregrinum*, which is sometimes puffed up as being rare and a superior form. One claim made for it is that it is more disease-resistant than the ordinary form. It blooms rather later, has a purplish black stem and thin spidery flowers, very narrow in the segments, and not recurving so gracefully as in the well-known white Lily. I always feel a sense of disappointment when I see its starry blooms, and wish it could have been the form that was best beloved of the dread fungus *Botrytis cinerea*. It is figured by Sweet in the second series of the "British Flower Garden," t. 397.

There is also a so-called double form, in which the axis of the flower is prolonged and bedecked with narrow white segments arranged spirally. When strong and healthy and favoured with fine weather, this production of segments goes on for some weeks, and a long spike of them is the result; but usually the inner ones damp off and a

singularly ugly decayed vegetable muddle is offered to view. It masquerades in lists at times under the names of var. *spicatum*, var. *monstrosum* or *flore pleno*. A very fine example of it was figured in *The Garden* for September 14, 1912.

As to the best way to grow and how and when to plant this tickle, fair jade, I do not believe the same process, however carefully repeated, would produce a similar result in any one garden for certain. How can one advise others, then? Some say transplant as soon as the flowers fall; others, just before growth recommences—that is, of course, the autumn production of radical leaves, so characteristic of this Lily. Doubtless both are right sometimes. Some twenty-five years ago I ordered some white Lily bulbs to plant in a churchyard. They arrived on a frosty December day, and I well remember the hopeless spirit in which I broke up the hard-frozen top inch of soil to plant them and the unpleasant way that biscuit-like, stiff, frozen portion refused to be replaced in any manner promising comfort to the poor plants. Yet never have I known Lilies thrive more

NOTES ON CHRYSANTHEMUMS.

BORDER PLANTS: SOME CHARMING VARIETIES.

GARDEN Chrysanthemums have become very popular during the last few years. The introduction of a number of new varieties of great beauty and dwarf habit has done much to make the border Chrysanthemum popular. Then, again, the deeper interest taken in the cultivation of the plants has had good results; they have been trained in a more natural form and given better positions. They have proved extremely useful not only in the vegetable garden, but also in flower borders, and yielded great quantities of blossom for the house vase. The earliest commencement to bloom at the end of July, and there is a continuous supply without any protection until the frost comes.

How Cultivators May Fail.—Many cultivators have failed to get the best from these plants in the past through neglecting to deal with them in the winter-time. All cultivators are not situated alike. Some have cold frames available at this season; others do not possess them. Now, the latter

THE THORN-LEAVED CRAB APPLE (*PYRUS CRATEGIFOLIA*), A BEAUTIFUL SHRUB THAT FLOWERS AT MIDSUMMER. (See page 48.)

successfully nor increase so happily as those two rows. I think the success was due to their being English-grown bulbs, and that, though hit at an awkward moment, they were not kept long out of the soil. The best advice, I believe, is to try all methods, and most probably the least reasonable one will succeed best. With a flower of this kind one never knows quite what is going to happen.

E. A. BOWLES.

(To be continued.)

should carefully examine the old roots (stools they are commonly called) and remove old stems, foreign matter and very weakly sucker growths. Then some fine sifted ashes must be neatly placed among the suckers and all round them to a depth of 2 inches. The ashes will protect the suckers from frost and slugs. Cultivators who possess cold frames may hit the old roots at once, and, after carefully dividing them, separating the strong young suckers which bear roots from the weakly

ones, transplant the former in the frame, 4 inches apart each way, in a bed or good sandy loam 4 inches deep. By the middle of April these young plants will be strong and branching and ready to be planted out in the borders again. In the meantime the border soil must be deeply dug and well manured.

Grouping to Secure Bold Effects.—A number of plants of the same variety should be planted together to form groups, especially in the case of broad borders. Where the borders are long and narrow, rows of distinct varieties look very well.

Yellow and Yellow and Bronze Varieties.—Cranford Yellow, Diana, Elstob Yellow, Etoile d'Or, Figaro, Jenny, Horace Martin, Harrie, Mrs. A. Thomson, Mrs. A. Beech, Leslie, Le Pactole, Arion, Polly, Tapis d'Or, Tonkin, A. Barham, Border Beauty and Cranfordia.

White Varieties.—Le Cygne, La Neva, Holmes' White, Hermine, Flossball, Emily, Dolly Prince, Caledonia, Bouquet Blanc, Mrs. W. J. Scott, Queen of the Earlies, Roi des Blancs, Savoie, Tapis de Neige, White Quintus and Anguste.

Pink Varieties.—Anita, James Bateman, Goacher's Pink, Gertie, Dolly Reeves, Lillie, Mabel Roberts, Mme. Aug. Nonin, Sally, Provence, Normandie and Mrs. Wingfield.

Crimson Varieties.—Roi de Precoces, Mrs. W. Sydenham, Mrs. E. V. Freeman, Wells' Crimson, Goacher's Crimson, Crimson Diana and Chaldon.

A Few Other Varieties.—Belle Mauve, mauve; Dolores, terracotta; Fedora, rosy lilac; La Somme, mauve and pink; Henri Yvon, rosy salmon; Mme. Marques, rosy white; Kabelaus, rosy purple; and Mandarin, red on a gold ground.

The Propagation of Border Varieties.—In addition to the division already referred to, cuttings may be inserted about the end of February and during the early part of March. They form roots quickly at that time, and the resultant plants should be put out in the borders during May. AVON.

BORDER CARNATIONS AND MILD WEATHER.

BOTH young and old plants have grown wonderfully this winter in many gardens, but it is in no sense assured that they will be the better for it when the flowering-time comes along. The extraordinarily mild and open weather which prevailed for so protracted a period literally forced progress when, in normal seasons, the plants would be almost completely at rest. Sparrows, if no one or nothing else, have been the gainers, because the growths are sweeter and more succulent than is customary, and the birds have not failed to ascertain the fact. It is apparent that the plants will be ruined by these feathered pests unless threading is done promptly and efficiently. Use very strong black thread, make a perfect network round and above each plant, and no further trouble will be experienced. When

the weather permits of it, the surface soil ought to be lightly pricked over with a planting fork, or even a bluntly-pointed stick, to encourage the admission of air; but it is necessary to guard against disturbing the roots, as this seriously prejudices the prospects of success. If it occurs through any cause, lose no time in properly refirming it. SENATOR.

THE THORN-LEAVED CRAB APPLE.

(PYRUS CRATÆGIFOLIA.)

AMID the wealth of handsome species belonging to the genus *Pyrus*, the subject of the illustration on page 47 must take a prominent

A HOUSE OF TOMATO MAGNIFICENT, A SEEDLING RAISED BY A READER IN THE ISLE OF WIGHT.

place; for while the bulk of the cultivated species are dwarf trees, the plant under notice forms a fine tree-flowering shrub, quite distinct in habit and general appearance from the rest of the genus. It further has the valuable characteristic of flowering about midsummer, when the bulk of the hardy trees and shrubs are over.

The stems are long, arching outwards, and wreathed with pure white flowers from top to bottom. These are about two-thirds of an inch in diameter and produced on short axillary clusters or leafy racemes, the flower-stalks being tinted with red. The leaves

are 2 inches to 3 inches long, of a rich dark green colour, ovate or nearly round, and beautifully divided around the margins. The whole plant is so strikingly distinct and handsome, even when out of flower, that I confidently recommend it to all lovers of hardy trees and shrubs. It is a native of woods in the northern part of Italy, where it is a somewhat local and rare plant. C. P. R.

THE KITCHEN GARDEN.

HINTS ON FORCING ASPARAGUS.

This much-esteemed vegetable can be forced most easily. A gentle hot-bed is the one essential, and this should be made up of about half fallen leaves and half horse-mannure. When enough has been obtained of each for, say, a two-light frame, which is, say, 9 feet by 7½ feet, the hot-bed should be made about one and a-half feet bigger all round, so that there is room to walk around and cut the heads, and this margin also allows of room to increase the heat if it should subside too quickly. The manure and leaves should be turned over several times to allow the rank heat to escape, when the bed ought to be made up evenly and firmly. Then the lights should be put on, and about three inches or four inches of fine soil spread evenly all over the surface of the manure, when the Asparagus roots should be placed on as thickly as possible. Another 3 inches of fine soil should then be placed over the crowns, or as much as will cover them, be it 2 inches, 3 inches or 4 inches. The roots should be procured at least three years old; if older so much the better; but if one has to buy the roots, three year old crowns must be obtained. After planting keep the lights fairly close, except for just a chink of air at the back of the frame to let off any vapour which may arise; but as soon as the heads appear, give more air. Cut when about five inches to six inches in length, and if not enough for a dish, the first cutting should be tied up neatly and placed in tins or saucers of warm water till the next morning. It is imperative that cutting should be done as soon as the heads are ready, as they quickly become drawn and weak. As soon as the Asparagus is finished, take out all the roots, burn them, fork up the sod, and add a little fresh soil. LEONARDSLEC. W. A. COOK.

A NEW SEEDLING TOMATO.

BEING a reader of THE GARDEN, I am sending you a photograph of a new seedling Tomato named Magnificent, which I have raised. There are fourteen plants in the border shown in the photograph. It is a splendid cropper, especially when grown in pots, the fruit being fleshy and of good quality.

Ryde, Isle of Wight.

J. A. BARRHAM.

GARDENING FOR BEGINNERS.

HOW TO PLANT GRAPE VINES.

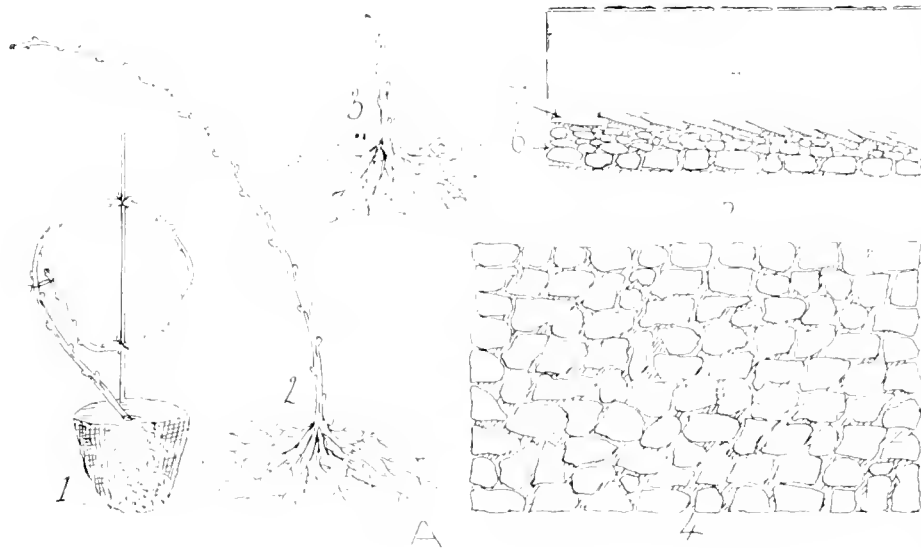

EVEN one Vine affords the amateur a great deal of pleasure when grown in an ordinary greenhouse with various kinds of pot plants. Very fine crops

washed down and blocking the waterway. Fibrous turves, chopped into pieces about four inches square, should be used to build up the border.

Fig. A.—No. 1 shows a "planting" Vine turned out of the pot; No. 2, the soil removed from the roots; No. 3, the young Vine rod cut back to about fifteen inches of its base. No. 4 shows how the stones and bricks should be laid to form the drainage; No. 5, the section of the drainage material, namely, No. 6, the stones and bricks, and No. 7, the layer of whole turves; No. 8, the body of the border.

Fig. B.—Nos. 1, 1, Vines planted in an inside border, the roots being able to enter the outside borders, Nos. 2, 2, through the arched walls; No. 3, stake to support the young rod to the wires, No. 4. No. 5 shows how a Vine should be planted in an outside border, the surface of the latter being covered with straw in winter, and the rod taken through the wall at No. 6 and trained inside the greenhouse. No. 7 shows the wrong way to make the hole through the wall, and No. 8 the right way.

G. G.

PREPARING INSIDE BORDERS AND PLANTING GRAPE VINES.

HOW TO IMPROVE LAWNS.

It is a fact that lawns usually present a better appearance in January and February than later on when the cold east winds prevail. The grass very rapidly recovers its freshness, however, when the winds become warm and showers of rain fall. Many lawns are improved by surface dressings of rotted manure and such material as road scrapings, which contain plenty of grit. Everyone cannot procure such material, but they can purchase some bone-meal, and this is one of the best and most lasting of manures for a lawn. The latter should be well brushed with a half-worn broom on a dry day; then sow the bone-meal evenly, applying it at the rate of 4oz. per square yard, afterwards well rolling the grass. Do not again roll or brush the lawn until a good shower of rain has fallen; then roll several times, taking the roller in different directions each time before the surface gets quite dry again. After an application of bone-meal the grass grows freely, but not coarse; indeed, the bone-meal induces a much finer growth. This surface-dressing of bone-meal must be put on before the middle of February. B.

of Grapes are often obtained from such Vines, and when an amateur has succeeded in growing Vines satisfactorily in a greenhouse, he often wishes to have a properly-constructed vinery in which he can grow several varieties of Grapes. The Vines may be planted any time from December to May; in the first months while the buds are dormant, and in the later months after the new growth has commenced.

Good Positions for Vineries.—In every case some protection should be afforded against the north and east winds; trees, walls and belts of shrubs a short distance away afford the necessary shelter. Lean-to vineries must have a position facing due south. A span-roofed vinery must have one end facing the north and the other facing the south; then the Vines get the maximum amount of light and sunshine. If it is intended to plant Vines in existing houses, they should be trained under the glass roof which receives the greatest amount of sunshine.

The Drainage and the Border.—Although the roots of Vines require ample supplies of water, stagnant water in the soil is very bad for them, so that thorough drainage is essential. Where there is a natural slope away from the vinery, it will only be necessary to provide rough drainage material under the border itself; but in cases where the ground is almost level, or the border is constructed below the surface, drain-pipes should be laid from the bottom of the border to the nearest and lowest outlet. Stones, clinkers, chalk and broken bricks may be used to ensure the drainage of the border. A total depth of 6 inches of this material will be quite sufficient for the purpose. On the hard material put down, whole turves should be laid grass-side down before the main body of soil is put in. These whole turves will last for many years, and prevent the finer material being

To the chopped turves add one barrow-load of old mortar rubble and one peck of half-inch bones to eight bushels of the chopped turves. No other kinds of manure should be added. A border of soil 2 feet deep will do nicely, and, where convenient, it may be constructed piecemeal; that is, a strip about four feet wide the first year, and then annual additions 2 feet wide until the whole space is filled.

Planting the Vines.—Carefully turn out the balls of soil and roots from the pots, and remove the cracks and soil without damaging the roots. Spread out the latter evenly, cover them with the finer portions of the compost, 4 inches deep, and give a good watering.

HOW TO MAKE AND PLANT INSIDE AND OUTSIDE VINE BORDERS.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Marguerites.—Those rooted in frames for bedding purposes have, owing to the mild weather, made rather more growth than usual. These should be potted off at once into suitable-sized pots and replaced in the frames, making sure that frost does not reach them. After they get well hold of the new soil, take out the point of each plant to encourage a bushy growth.

Calceolarias also are very forward in growth; but as it is somewhat early to pot up or replant these, all the air possible should be given them. Any decaying foliage should be removed, and if the plants are getting unduly long, take out the point of each plant, then by the time they have broken into growth they may be either potted up or replanted in cold frames, giving them more room.

Melianthus major.—This I look upon as one of our best subtropical bedding plants, and it deserves every care to get good specimens for planting out. Seeds sown in the autumn make good plants, and should now be ready for potting off into 4½-inch pots. They require very little heat—just sufficient to keep them growing steadily. Seed sown now will make nice little plants if pushed along quickly, but they are not so effective early in the season as the autumn-sown ones.

Abutilon Thompsonii.—These should be potted off out of the stove pots into 3-inch pots, transferring them later into 4½-inch or 6-inch. To secure good plants they should be grown on for a time in an intermediate temperature, taking care they do not get drawn by being placed too closely together, or it will rob them of their tendency to make side-growths, which is so essential when they are used as dot plants.

The Pleasure Grounds.

Azaleas.—Beds of Azaleas do much better after they are well established if given a mulch of short manure, or manure and leaves mixed, during the winter months; so if not already done, it may be carried out at once.

Rhododendrons may be treated in the same way, and if old hot-bed material is to hand, it will suit them admirably.

Plants Under Glass.

Hydrangeas.—Select the most promising of last season's rooted plants and place them in a house with an intermediate temperature, and as soon as growth commences they may be assisted with manure-water. Being very gross feeders, they must not be neglected if good heads of bloom are wanted. Mme. E. Moullière, one of the newer French varieties, is a distinct acquisition, and may be had in flower during the greater part of the summer.

Schizanthus.—Put these on into their flowering pots as soon as they are fit, using a fairly rich compost, a check at any time being very detrimental to the growth of these plants. Make a sowing in 3-inch pots as a succession to the autumn-sown plants. The retusus varieties in small pots are particularly useful during the summer months for grouping purposes.

Forcing Plants, such as Laburnums, Azaleas, Viburnums, Pyrus and Wistaria, force easily and well if placed indoors about this date, a temperature of from 55° to 60°, with a gentle spraying overhead two or three times each day, being all that is required to ensure success with them.

The Kitchen Garden.

Peas: Sowing Under Glass.—For very early work a sowing of first-early varieties should be made at once, either in pots, boxes or trays. Also for exhibition purposes it is advisable to sow a box or two of the best varieties; this ensures a dish or two during June if they are required. To ensure good germination and a stocky growth, a temperature of 45° to 50° is sufficient.

Broad Beans.—These also may now be sown in pots or boxes, and when the nature of the soil is such that they cannot be sown outdoors in the late autumn, this early sowing in pots will give a crop equally early.

Potatoes.—For planting in frames and for early crops on warm borders, the tubers should be spread out in trays and placed in a slightly-heated house, where they will soon break and make strong, robust

shoots, which will, when planted, soon make headway. Sharpe's Victor, Sharpe's Express and May Queen are varieties that can be relied on for early crops. During bad weather all seed Potatoes should be picked out and placed in trays, as advised, and it might not be out of place to mention that Potatoes, more than any other crop, pay for a change of seed.

Fruits Under Glass.

Figs.—For very early work, pot Figs are probably more in favour than those planted permanently in the houses, as they can be rested somewhat earlier in the autumn; this being so, they respond more readily to early forcing. After thoroughly cleaning and top-dressing, if necessary, the pot trees should be started in a temperature of 50° to 55°, allowing a fair rise with what sun-heat there is during the day. A fairly humid atmosphere must be maintained by the use of the syringe, but too much water at the root is not necessary for a time.

The Hardy Fruit Garden.

Pruning Standard Trees.—After completely pruning the trees in the enclosed garden, those in the outside orchard should be taken in hand. Young trees do not need much done to them except the removal of branches which may be crossing each other, or that may be crowding up the centre of the young trees.

Older Trees may need more systematic treatment, and should cold weather stop the ground work, this is a matter that may well be taken in hand, as old trees that are thinned out intelligently, with due consideration to the style and habits of the individual varieties, may be brought into such a condition of fruitfulness that they will compare very favourably with the younger trees.

Spraying.—After completing the above operations, it is advisable to give all the trees a thorough spraying with caustic alkali. This removes all moss and lichen from the trees, as well as many of the insects that take refuge under the loose bark.

THOMAS SILVENSON.

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Trenching and Digging.—The digging or trenching of all open quarters should now be completed as speedily as possible, so that the up-turned soil may receive the pulverising effects of air and frost. Deep cultivation is of even greater value than liberal manuring. I would therefore recommend that all ground should either be trenched or bastard-trenched. By the former process the soil is usually dug two spits deep, the whole mass of soil being inverted. By the latter process the soil is usually dug the same depth, but the top and bottom spits are left in their relative positions. The latter method is better in the case of soil which has not been so deeply moved for several years.

Manuring.—Both kind and quantity are often a question of ways and means, but a certain amount of humus should always be afforded, in order to keep the roots cool and moist during hot, dry weather. A more liberal supply should, of course, be given to ground which is to be occupied by such gross feeders as Dahlias, Hollyhocks, Sweet Peas and Chrysanthemums than that on which the lighter annuals are to be grown.

Sweet Peas.—Where these are to be grown in rows and really good results are desired, trenches should be dug out and a good heavy dressing of farmyard manure placed at the bottom of the trench. A portion of the soil should be removed, replacing it with some old Melon or Chrysanthemum soil. A dressing of soot should be incorporated with the top spit.

Dog's-Tooth Violets, where growing in beds or masses, should receive a top-dressing of fresh loam.

The Rose Garden.

Labelling.—Where necessary, labels should now be renewed, and this raises the vexed question as to which is the best label. I was very partial to the Acme Label-Rest, which I regret is no longer on the market. I now intend to go in for the

Acme Rose Label, with raised letters. This can be suspended with lead wire, which is easy of manipulation when the branch from which the label is suspended has to be cut away at pruning-time.

The Pleasure Grounds.

Laburnums of considerable age have a knack of splitting at the fork, which generally occurs a few feet from the ground. If not too long neglected, the evil can be remedied to some extent by placing an iron band round the trunk immediately under the fork. The band should be about the length of the normal circumference of the trunk, and the ends, each of which should have an eye pierced in it, should be turned out at right angles. A screw-bolt should then be inserted into the two holes, and, the nut having been adjusted, the band can be tightened up by means of a screw-key. The wound, if still gaping, should be filled up with cement.

Turfing.—If any slight depressions occur on the lawns, the turf should be rolled back in convenient breadths, the ground levelled up firm, and the turf replaced and firmly beaten. If the soil used for this purpose is much richer than that of the lawn, the grass will grow stronger than the rest and look patchy.

Plants Under Glass.

Gloxinias.—A portion of the stock should now be started. Shake the tubers out and place them in a shallow box among some flaky leaf-mould and sand, only partially covering them. Place in a brisk temperature and spray daily with slightly tepid water. Last year's late seedlings which have been kept slowly moving during the winter should be potted on.

Achimenes.—An early batch of these may now be started. The stolons should be placed about an inch apart on pans partly filled with light, rich soil. They should then be slightly covered with a little of the soil which has been passed through a fine sieve. Place the pans in a brisk temperature and keep the soil moderately moist. Keep near the light when growth commences, as they are easily drawn.

Fruits Under Glass.

Vines.—Tying down the shoots in the early house will now be necessary, although present-day cultivators wisely defer the work till a later stage than our forefathers did, thereby lessening the risk of snapping. But, even so, care must be taken not to bend the shoot too far at the first tying. It will still further reduce the risk of snapping if the operation can be performed on the afternoon of a sunny day, when the shoots are more or less limp.

The Hardy Fruit Garden.

Planting of all kinds of hardy fruit trees is best done immediately after the fall of the leaf. Where it was impracticable to carry out the operation at that season, it may be proceeded with now, provided the weather is open. The aim of the cultivator should be to keep the roots near the surface, and the system of planting on the surface and covering the roots with good soil (maiden loam for preference) has much to recommend it.

Stocks and Grafts.—If not already done, all grafts should be cut and their bases inserted in the ground in a shaded position, in order to keep them plump. Stocks should be headed back, also any trees on which it is intended to work grafts.

The Kitchen Garden.

Horse-Radish, although possessing great vitality, can only be produced in good condition by liberal cultivation. Trench the ground from 2 feet to 3 feet deep, working in old decayed manure and decayed vegetable refuse. Plant the upper portion of the thongs with the tops pared off.

Cauliflower.—A sowing of some early variety, such as Snowball or Early Eriurt, should now be made in a cool greenhouse temperature.

Brussels Sprouts.—Many people prefer sowing now, as directed above for Cauliflower, instead of sowing in the open in autumn. There are few things that a gardener is so often disappointed with as the seed of Brussels Sprouts; hence the reason why so many save their own seed.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mans, Midlothian.

PRACTICAL HINTS ON TABLE DECORATION.

I UNDERSTAND there is much table-decoration still carried out with mud for a foundation, and yet more, perhaps, with flowers arranged in receptacles of many shapes and sizes. Whether the dainty fashion of arranging a varied vegetation on the cloth obtains to any great extent, I do not know, but it has advantages that cannot be claimed for other methods, the greatest of which, no doubt, is that of causing no obstruction between the diners on opposite sides of the table. At the same time it yields to none in effectiveness, though it must be allowed that in clumsy hands there is a certainty of its being a shocking failure.

It must be allowed, too, that all kinds of flowers cannot be used with success. Zonal Pelargoniums, for instance, brilliant as they are at this season, are far too modish unless trusses with only two or three open pipes are used. Carnations are also a difficulty, though in their case they may be employed in loosely-arranged sheaves. This differentiation of ways of using particular flowers is a feature of flat decoration that must not be overlooked in estimating its advantages. Each flower has a way that it must be arranged in order to bring out its beauty to the fullest extent. So while we would make sheaves of Carnations and employ only a few, comparatively, *Cypripedium*, such as *C. insigne*, would be arranged so as to exhibit every part, the purple stems being in their way as important as the "slippers." Carnation foliage and buds are suitable for Carnations. *Cypripedium* leaves are less to be preferred than narrow-leaved *Crotons* for *Cypripedium*s. *Gloire de Lorraine* *Begonias* are exquisite if arranged in small pieces with a little of their own foliage in very finely-leaved sprays of *Smilax*. *Lenten Roses*, again, go best in wreaths with a very few of the smallest of their own leaves and the greenery on their flower-heads with plenty of buds, and, perhaps, a few pieces of the curiously-twisted *Muehlenbeckia complexa*.

A very nice effect is produced with *Plumbago rosea* in sprays, and *Apera arundinacea*. *Humea elegans* is also suitable but not so dainty. A limited number of kinds of *Chrysanthemums* afford a desirable change, and of these the most effective is undoubtedly *Mary Richardson*. *Emily Wells* and *Jessie Angus* are also good, and I grow two *Pompon Anemones* without name, the one pink, the other brown, both of which are indispensable. Usually these are all best arranged in neat little bunches with selected foliage. *Smilax*, *Crotons* and material of that kind should not be used with them.

Quite a distinct effect is produced with *Jasminum nudiflorum*, with plenty of its thin shoots mixed with the flowering and budded ones. Sometimes a very marked distinction may be effected by introducing a very few fine trails of *Vinca minor*. *Cymbidiums* are particularly desirable—*Lowii*, *tracyanum* and chestnut brown ones—and all are best used with the flowers detached from the stems. For these perhaps there is nothing more suitable for a setting than *Crotons* and *Asparagus Sprengeri*. There are, of course, many more combinations equally effective that can be produced from the employment of Star-flowered *Primulas*, *P. malacoides* and *Cyclamen* of the right colours, deep crimsons and salmon being the best. As a rule, one need not be afraid to use strong colours

For a while last autumn there was quite a run on a deep crimson *Lobelia* of the cardinalis type. It is much to be preferred that nothing should be on the cloth with the exception of a little plate, and underdo the amount of material rather than have too much.

Most flowers will last quite fresh over the dinner-hour if previously placed for several hours in water—in some cases the stems merely; in others, e.g., *Hellebores* and *Begonias*, the flowers also are immersed. Some flowers are of no further use afterwards, but the majority are as valuable as before for furnishing vases. *Cypripediums* which did duty three weeks ago are still quite fresh, and, indeed, the majority of the flowers are none the worse for the ordeal. *Plumbago rosea* is one of the worst to stand. Quite fresh, well-budded sprays only should be used, and not be arranged till the last possible moment.

R. P. PROBERTON.

SOME LITTLE-KNOWN HARDY FLOWERS.

CALANDRINIAS AND LEWISIAS.

[In answer to a Correspondent.]

CALANDRINIAS and *Lewisias*, closely-allied plants, together form a class of alpine flowers which deserve and require the full care of all admirers of rock gardens and the gems which adorn them. The difficulties they present in the way of culture only whet the desire of the cultivator to succeed with them, and he may well consider himself happy who can manage to grow these beautiful flowers for a term of years in the open. There are about one hundred and forty species recognised by botanists, the vast majority being classed with the *Calandrinias*. The botanical distinctions between the two genera are, however, so small that the distinguishing point—that of the opening of the capsule—is often unknown to the botanist, with the result that several of the true *Lewisias* are frequently included among the *Calandrinias* by high authorities, so that it is difficult to separate them unless they have seeded in one's own garden or have been fully distinguished by competent botanists. The sole difference between the two lies in the debiscing or opening of the seed-capsule. That of the *Lewisias* opens from the base to the apex, the capsule of the *Calandrinias* opening in the opposite way. With such a small distinction it is unfortunate for garden purposes that they have been separated.

A considerable proportion of the *Calandrinias* can only be classed as annuals or biennials with us, and seeds of only a few of these are ever offered by British seedsmen. Like the perennials, they have rather succulent foliage and beautiful flowers, and, like them, they should have a dry, warm and sunny position to do them justice. They are best sown where they are to bloom, and may be treated like other half-hardy annuals. If treated as biennials, they should be kept under glass all the winter and planted out in May after being hardened off.

The perennials can also be sown in the open where they are to bloom; but it is desirable to sow the seeds under glass in spring, planting the seedlings out in the course of the summer, so that they may become established before winter if they are to be allowed to take their chances of standing the seasons in the open. If not, it is better to grow them on in pots for the first year,

keeping them near the light in a low house or frame in summer and in a slightly-heated house in winter. They are difficult to manage in a cold frame in winter, and a minimum of heat, just sufficient to exclude frost, is better than a higher degree.

The soil for the *Calandrinias* and *Lewisias* should always be light, sandy and well drained, and the writer has found the perennial species to thrive better if jammed between two stones, on which the foliage rests, unless planted in a moraine, probably the best treatment of all. They do not seem to require lime, nor are they averse to its presence in the soil.

Remarkably few of the annuals are available in the form of seeds, and the few offered in catalogues are but little known in gardens. Even some of the described species in works of reference are not obtainable at all in the trade. Of those which are offered by some specialists is included *C. chromantha*, a most ornamental plant, growing about three feet high, and bearing elegant sprays of little *Gypsophila*-like pink flowers, which are followed by small orange berries. *C. discolor*, another annual or biennial species, is only about a foot high, and affords a succession of large and handsome rose-coloured flowers. These are, I believe, all the annuals offered at the present time in Great Britain. *C. procumbens* and *C. umbellata* have also been cultivated.

One of the best known of the allied plants is *C. umbellata*, a very beautiful subject for the rock garden. It is of rather shrubby habit, grows about six inches high, and has large crimson flowers with a tinge of magenta, which is a drawback to its popularity. There is, however, a variety called *carnea*, with blooms of a pleasing flesh pink. Unfortunately, *C. umbellata* cannot be relied upon to stand our winters, although it may survive for a short series of years. It is safer to treat it as a biennial, though seeds sown early will give plants which will flower in the autumn.

A charming *Calandrinia* called *C. leeana* has been in cultivation, but appears difficult to secure at the present time. It makes a close tuft of succulent foliage and bears a number of small pink flowers. It is a very charming little subject, and one which the writer retained for several years on a flat terrace of a sunny rockery, facing full south and in sandy soil, surfaced with fine gravel to a depth of about an inch. Although its flowers lack the size of some of its allies, they are so freely borne that they more than compensate for their smaller size. This species has stood for several years in stiff soil also, but it is not a long-liver, generally rotting off at the neck and requiring to be replaced by seedlings or by cuttings, which are difficult to strike except in gentle heat.

C. oppositifolia, which was figured in THE GARDEN of November 28, 1891, is a very beautiful plant, with larger leaves and flowers than those of *C. umbellata*. The blooms are white, and those who have access to this journal of the date mentioned will find a faithful representation of this now scarce *Calandrinia*. It is a pleasing little plant, which, like most of its allies, will frequently survive for a season or two, but is not a long-liver in our climate. A dry, sunny spot should be chosen for it.

In the notes by the late Mr. Daniel Dewar which accompanied the illustration in THE GARDEN, mention is made of *C. Gilhesii* and *C. setosa* as so closely related to *C. umbellata* as to be hardly distinguishable from it. These do not at present appear to be in cultivation, and *C. Menziesii* or *speciosa*, rose purple, is apparently not now offered.

So far as I am aware, no other perennial Calandrinias, as distinct from the Lewisias, are at present available, and we may now turn our attention to the latter, which are of great beauty indeed, and whose popularity in gardens is only limited by the drawback which attaches to their allies—that of short life. They are charming plants, requiring the same treatment as the Calandrinias, and giving, where they are happy, handsome flowers and pleasing plants in every way.

It was to THE GARDEN that those interested in the genus were first indebted for an illustration of the charming *Lewisia*, then called *Calandrinia Tweedyi*, as it was figured in these pages in Vol. LIII., 1868, page 420, when the plant attracted much attention. It is a lovely, dwarf, tufted plant, with flowers which are red in the bud, and of a pleasing flesh colour, edged with bronze, when fully open. It has been several times figured since then, and has been much admired wherever seen. It is an Oregon plant, and is said to be very plentiful in some parts. Like the others, it was considered hardy, and stood the winter for some years, even in Cheshire, as well as further South. It is not, however, so reliable as was at one time believed, and wet in winter is one of its greatest enemies. *L. Tweedyi*, or *Tweedii* as it is often spelt, received an award of merit at the Temple Show of 1901, when it was exhibited by Messrs. Barr and Sons. An illustration will be found in the *Botanical Magazine*, t. 7633.

Another acquisition among the Lewisias was presented at the Temple Show of 1911 by Mr. G. Kuntze, who received an award of merit for the lovely *Lewisia* or *Calandrinia Cotyledon*, which is fittingly said by the *Journal of the Royal Horticultural Society*, Vol. XXXVII., Part 2, where it is also figured, to be "the most beautiful of the genus." It was, I am informed, raised from seeds sent from Klondyke, and is probably the most enduring of the Lewisias in our climate, although winter wet is its bane also. It has exquisite white flowers, fully an inch across, with a distinct crimson band along the centre of each petal. The pretty leaves, in rosettes, are fleshy and green, ringed with pink at the margins. But for the winter wet this would be an assured favourite.

Following on this, last year Mr. Maurice Pritchard received an award of merit from the floral committee of the Royal Horticultural Society for *L. Howellii*, another charming plant, with rosettes of succulent leaves, lanceolate in shape and tinged with pink. The handsome flowers are of a kind of creamy apricot, marked with lines of rose, and are borne in good umbels. It is another great acquisition to our gardens, but is no more to be relied upon than the others.

The best known of the Lewisias is the old *L. rediviva*, which is said to have again sprung into growth after being in a herbarium for a long time, and which has been in cultivation for a number of years. It is fairly well known, its succulent leaves in rosettes and its large flowers, which do not expand until the leaves have withered, making it a handsome plant, though it is marred by the absence of leaves when in bloom. It should have a warm, dry, sunny place, but some cultivators give a good supply of moisture at the roots, while keeping the neck of the plants dry. This also is liable to injury from wet, and although living for years, sometimes dies off unexpectedly from rot. Another *Lewisia* or *Calandrinia* which is to be met with in one or two lists is *nevadensis*, but I have had no experience of this species.

The favour with which these plants have been received will doubtless lead to the introduction of other beautiful Calandrinias and Lewisias, and were it not for their want of reliability in our climate, these lovely members of the great Purslane family would be assured of permanent favour.

S. ARNOTT.

THE FRUIT GARDEN.

THE THINNING OF FRUIT TREES.

"HE believes in spraying a lot, but I believe in keeping my trees thin." This was a remark I overheard made by one individual to another in the Royal Horticultural Hall on the occasion of the last great show of British-grown fruit. There is not the least doubt that there is a tremendous lot of truth in the idea underlying the above expression of the different growers' creeds. It will be a very long while yet before we are able to dispense with spraying as an aid to growing a good crop of large, clean fruit—particularly of Apples—but it is quite certain that such a task is rendered far more easy if the trees are kept sufficiently open so that all the sun and air possible is allowed to circulate through the branches, rather than if choked with growth so thick that light and air can hardly penetrate at all. A casual examination of overcrowded fruit trees during the fruiting season will reveal the fact that all the fruit worth calling by that name is on the outside of the tree, and nothing at all is borne by the thick growth inside. The work may be done at any time during the winter months, though I prefer to do it early in the autumn, just before the leaves fall, as one can then tell better exactly how much to cut out.

The first thing to do is to remove any of the lower boughs which are too low, or which have become stunted and unthrifty. Next, all the small boughs and twigs which are encumbering the main branches of the tree must be cut off, taking care to cut right close home; otherwise, if even the smallest snag be left, shoots will spring from it and become a nuisance later. After this has been done it will be found that a considerable improvement has been effected in the appearance of the tree, and it will now be possible to turn the attention to the better outside growths, which are perhaps growing across the tree or are ill-placed according to the general shape and symmetry of the tree. In this work some caution must be observed, removing smaller rather than larger pieces at a time and the worst first. Wherever the saw has been employed to remove a bough, the rough edges of the wound must be pared round with a knife to enable the bark to callus over and protect it as soon as possible. With the same end in view, all wounds above an inch in diameter should be painted with a styptic of some sort, to prevent the entrance of the spores of any of the wound fungi till such time as the new bark has completely healed the wounds over. A good thing to use is a red or white lead paint made with pure linseed oil, but without turpentine. This will be found to set quite hard on the cut surface, and to remain in good condition and without flaking off for a long time. Stockholm tar can also be used, but not gas-tar, unless the pruner is dealing with very old trees indeed. After a tree has been well thinned, it is not necessary to repeat the process

the next winter. About every three years will be often enough to prune in the case of old-established orchard standards.

Pilgrim's Hatch, Brentwood

MISCELLANEOUS.

BUYING MANURES ON ANALYSIS.

THE Fertilizers and Feeding Stuffs Act was amended in an important respect when the latest Act (1909) was passed. Small purchasers of manures were protected in the same way as larger buyers, who stand, perhaps, in less need of it. Before this date the provisions of the Act did not apply to quantities of less than a ton, but this has, fortunately, been amended, and buyers of any quantity have a right to know the percentages of nitrogen and the other two ingredients covered by the Act—phosphates and potash. Another point worth noting under the same Act is that where such percentages are mentioned in an artificially-made manure, the purchaser now knows the actual, and not merely, as heretofore, the minimum, amounts of the different constituents. These provisions are valuable, for cheap grade manures are often traps for the unwary, and often very uneconomical. Attention is drawn to organic matter, alkalis or other substance not covered by the plain terms of the Act, and which, therefore, should not be valued at all. Low grade fish-manure, for example, should be bought with great care, and statements that the phosphates are "partially soluble" should not be accepted. In a recent case submitted to the writer, this description accompanied a singularly poor manure, in which attention was called to the "organic matter," and a high price was charged, quite out of proportion to the percentages of the ingredients which possessed a marketable value.

HOW CONTACT INSECTICIDES KILL.

INSECTICIDES kill in various ways, and it is supposed that those to which the above term has been given do so by causing suffocation. Little is known, however, about the way in which such insecticides do their work, and experiments have shown how very difficult it is to kill many insects in a reasonable time merely by excluding air. The agricultural authorities at Michigan College, U.S.A., have been putting this to the test, and have come to the conclusion that death must be due to another cause, because insecticides like kerosene and gasolene kill quickly, and this points to something more than a stopping up of the breathing apparatus. Several insecticides, too, were found to be as effective in a state of vapour as in the liquid form, which confirms these conclusions. The results of these experiments, however, still seem to show a connection between the breathing apparatus and death, because it appears that the absorption of oxygen is in some way interfered with by such agents as creolin and pyrethrum. This seems to account for their speedy action, for in the form of vapour these insecticides were found to penetrate the chitine far more quickly than liquid or powder could do. For rapid action, then, vapour seems better than spraying.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

*The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.*

NOTES OF THE WEEK.

Double Daisies in Pots.—The owner of an unheated greenhouse might derive considerable pleasure from now onwards from a few potsful of double Daisies. Although these are not everyone's flower, they are highly appreciated by many. Plants lifted from the outdoor garden now with good balls of soil and potted up into 5-inch pots will scarcely notice the disturbance, and if placed in a cool greenhouse will quickly give a beautiful display of flowers. More use should be made of hardy flowers in the cold greenhouse, instead of attempting to grow plants which need a comparatively high temperature to bring them to perfection.

The Tamarix.—Owing to the mildness of the season the young buds on these plants are becoming very prominent. The Tamarix is a splendid plant for growing on exposed sandy banks in or near gardens by the sea. We know of many plots of large size now well covered with the plants where it would be difficult to establish other kinds. We know, also, of many plants whose roots are covered with sea water at high tide, and the growth of these, too, is very satisfactory. Cuttings soon root if inserted in a sandy compost under a hand-light or in an ordinary frame early in spring.

Planting Fruit Trees in Spring.—Although November is the ideal month for planting fruit trees, and the work is always best done then when possible, it often happens that for some reason or other the trees cannot be put in at that time. We are often asked whether it is impossible to plant fruit trees or bushes at any other time, and unhesitatingly answer "No." We have on many occasions planted fruit trees in February and the early days of March, and such trees have invariably done well. The soil must not, of course, be frozen hard nor sodden with water. Plant in November if you can; if not, do the work during open weather in February.

Pensions for Aged and Infirm Gardeners.—On another page we give particulars of the annual election of aged and infirm gardeners, or the widows of gardeners, to the funds of the Gardeners' Royal Benevolent Institution. During the seventy-four years the Institution has been in existence it has brightened the lives of a vast number of those who, through no fault of their own, have fallen on evil times. We would remind our readers that these are men, or the widows of men, who so much to their earlier and happier days done so much to give us the flowers and fruits that we now enjoy. What a pension of £20 a year means to these unfortunate and destitute people only the committee of the Institution perhaps know. We urge those of our readers who have enough and to spare to send a donation towards the funds to the secretary, Mr. G. J. Ingram, 72, Victoria Street, Westminster. By so doing they will have the satisfaction of knowing that they are bringing some ray of hope to

those who in the past have given of their best to brighten the lives of others.

Mimosa in the London Markets.—During the last two or three years the species of Acacia sent from the South of France to the London markets at this season has been changed. A few years ago the Silver Wattle, *Acacia dealbata*, was practically the only one sold as Mimosa, but it has now been almost superseded by *A. baileyana*. The latter is the more graceful of the two in a cut state, the smaller and softer glaucous, deeply-serrated leaves and the long racemes of globular, bright yellow flower-heads making an ideal spray for vases. It would be interesting to know why the growers have almost dropped the cultivation of *A. dealbata* for this new-comer.

A Beautiful Early-Flowering Crocus.—During the last few weeks the charming little *Crocus Sieberi* has been giving us its rich lavender blue flowers in the outdoor garden, but owing to the sunless, damp weather that has prevailed, they have seldom got beyond the balloon or unopened stage. This is unfortunate, because much of the beauty of this *Crocus* lies in its rich orange stigmata, which can only be seen when the flowers are fully opened. A few days ago we potted up a few plants in some damp fibre and moss and took them into a warm room, where the flowers quickly expanded and revealed to the full their beautiful interiors. We pass on the hint to others who may care to try it.

An Effective Grouping.—A pretty effect is now to be seen in the Temperate House at Kew by the bright red flowers of *Cestrum elegans* and the yellow blossoms of *Acacia verticillata*, the two plants growing side by side and being covered with flowers. Although it is impossible, except in those establishments where there are large winter gardens, to allow the plants to develop so freely as in the case referred to, a similar effect on a reduced scale can be produced by most people who possess a moderate-sized greenhouse, for both plants are easily grown, while other species of *Acacia*, such as *A. armata* or *A. Drummondii*, both of which thrive excellently in pots, might be substituted.

An Early-Flowering Almond.—It is not unusual to see flowers on the Chinese *Prunus davidiana* towards the middle or end of January, but it can have rarely happened that a variety of *P. Amygdalus* has been in full flower during the third week of January, yet such was the case this year. The variety in question is *persicoidea*, a form which usually blossoms early in or towards the middle of March, a fortnight or so in advance of the type. Its precocity this winter, however, is remarkable, and is doubtless due to the exceedingly mild winter which has been experienced in the South of England. The tree specially noted is growing in an enclosure surrounding the flag-staff at Kew, while another tree, similarly flowered, was seen about the same time in the churchyard at Kew.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Plants and the Mild Weather.—I imagine the abnormal condition of vegetation is due to the hard frost in November, which gave the necessary check to vegetation, and to the nice weather that followed. There is here a Sycamore in full leaf, and a hedge of Mahonia Aquifolia has been in flower since the New Year, while Montbretias, which were very late in flowering last year, already have shoots several inches in length. Flowering Currants are also far in advance of a normal season. That the weather of last April and May could affect these, as Mr. Bowles seems to think, is scarcely to be credited.—R. P. BROTHERSTON, *Tynninghame, Prestonkirk, N.B.*

Rose Sarah Bernhardt.—May I add a contribution to the notes which have appeared in your columns relative to this Rose? I was a little surprised that Mr. Molyneux should have included it in his list of new Roses, seeing it was raised by

In the first place, it is at least doubtful whether it is wise to transplant this Iris in spring. Growth obviously begins when the soil becomes thoroughly wet in autumn, and continues, except for interruptions by hard frost, until midsummer. As a general rule, it may be said that Irises should be transplanted while growth is active and, if possible, when growth first becomes active. In the case of *I. unguicularis*, this usually begins early in September, and I am inclined to think that this is the best period at which to transplant this Iris. Provided the plants are placed close to the foot of a warm, sunny wall in somewhat poor, light, well-drained soil, the number of flowers produced seems to depend on the weather, although it has been a surprise to find that plants are blooming fairly well this winter in spite of the lack of sun in the latter part of the summer. Last winter, when the flower-buds had formed in vast numbers during the long summer drought, the majority of them were killed by hard frosts before they had had time to develop, and when their presence could only be detected by dissecting the base of the growths. If the plants can be given a sunny position in suitable soil close

to the foot of a greenhouse wall, where they reap the benefit of warm pipes on the other side of the wall, they seldom or never fail to produce their crop of flowers.—W. R. DYKES, *Charterhouse, Godalming.*

carinata, *Hymenanchera crassifolia*, *Jasminum primulinum*, *Lonicera syringantha*, *Lithospermum prostratum* Heavenly Blue, *Loropetalum chinensis*, *Libonia floribunda*, *Medicago arborea*, *Prunus pissardii*, *P. davidiana*, *Pyrus nivalis*, *P. Maulei Sargentii*, *Polygala Chamæbuxus* and the variety *alba*, *P. dalmaceanum*, *Pieris floribunda*, *Ribes speciosus*, *Rubus speciosus*, *Sycopsis sinensis*, *Veronica macrocarpa* and *Viburnum rhytidophyllum*.—H. W. GRIGG, *Cann House, Crown Hill, South Devon.*

Old Cyclamen Plants.—It is the general practice in cultivating *Cyclamen persicum* to treat it as an annual, and really well it succeeds managed in that way; but one occasionally comes across plants several years old which are also a success. In the gardens at Corhampton House, not far from where I write, Mr. Cawte, the gardener, has a fine batch of plants now coming into flower that are several years old, and remarkably well they promise, being furnished with large, healthy leaves, and throwing up a quantity of really fine flowers. The treatment the plants receive after flowering is, they are gradually dried off, stood at the foot of a north wall, and, when they show signs of new growth in July or August, the old soil is shaken off the roots, and the corms are freshly potted in a fairly rich compost, stood in a cold frame for a time, carefully watered, daily syringed, and, as the autumn comes along, they are removed to a shelf close to the glass in a cool greenhouse.—E. MOLYNEUX, *Swanmore Park, Hants.*

—After reading the note on "Old Cyclamen Plants" on page 29, issue January 18, I feel tempted to write you my experience with them. When taking charge of these gardens four years ago there was a batch of nearly two dozen plants, all from about ten to fifteen years old, I should think. The best had a dozen or so blooms. As soon as the plants had finished flowering they were put into a frame in full sun, watered until the foliage began to turn yellow, then dried off until some corms shrivelled. In August all the soil was shaken off, and they were potted up in a good mixture of loam, leaf-soil, sand and road scrapings, put back into the frame again, kept fairly close and shaded, and we syringed between the pots twice daily. In October we put them into a house with a temperature of 45° to 50° and carefully watered them. The next spring I selected fifteen of the finest plants. The best of these had 120 flowers, the smallest had eighty.—ALBERT JAMES, *The Gardens, Winsford Hall, Great Yarmouth.*

A Sweet Pea Enthusiast.—Among those who take a particularly keen interest in Sweet Peas is Mr. C. F. Faulkner of Clevedons, Park Avenue, Hale, Cheshire. For fourteen years Mr. Faulkner has grown Sweet Peas extensively, and each year has set himself the laudable task of distributing sprays and buttonholes of the flowers at garden fêtes, crippled children's picnics and similar functions. In the accompanying illustration he is seen distributing Sweet Peas in front of the Town Hall, Manchester, on the occasion of the picnic arranged for members of his firm last summer. Mr. Faulkner is a provincial corresponding member of the committee of the National Sweet Pea Society, a past president of the Altrincham and District Chrysanthemum Society and the Altrincham Gardeners' Mutual Improvement Society, as well as a patron of several other horticultural societies in the district. He is also a vice-president of the National Auricula and Primula Society (Northern Section).—W. J. W.

MR. C. F. FAULKNER DISTRIBUTING SPRAYS AND BUTTONHOLES OF SWEET PEAS IN FRONT OF THE TOWN HALL, MANCHESTER.

M. Dubreuil in 1907 and sent out in 1908. I was first attracted to it by seeing fine bushes of the variety in Messrs. Paul and Son's nursery in 1909. The following autumn we had a plant or two, and in 1910, perceiving it to be a valuable addition to the decorative section and superior to Bardou Job, we increased our stock, and have grown and exhibited it ever since. Mr. Molyneux classes it as a pillar Rose. It may be so in his climate, but not in ours. It flowers from the top of the shoot, not the laterals, and should be moderately pruned, leaving the shoots about three feet high. With us it is a good bush Rose, flowering best in a dry season, early and late. It may be best described as a semi-single Horace Vernet, producing some six to a dozen blooms on a stem.—JOSEPH H. PEMBERTON

Treatment of Iris unguicularis.—A note on *Iris unguicularis* (*stylosa*) in THE GARDEN, page 2, issue January 4, suggested that transplantation in spring might induce clumps of this Iris which had remained flowerless to produce a crop of blooms.

to the foot of a greenhouse wall, where they reap the benefit of warm pipes on the other side of the wall, they seldom or never fail to produce their crop of flowers.—W. R. DYKES, *Charterhouse, Godalming.*

Plants Flowering on January 20.—The list below represents plants in flower on January 20 in the gardens at Cann House, most of which are not due to bloom for many weeks. I have purposely omitted many commoner shrubs, and have only included the rarer species. I should like to add that *Primula Winteri*, a recent introduction from the Himalayas, is making a brave show in the open. *Aotus gracillima*, *Azara microphylla*, *Akebia lobata*, *Berberis Bealii*, *Banera rubioides*, *Brachysema Drummondii*, *Boronia megastigma*, *Camellia japonica*, *Clematis balcarica*, *Ceanothus rigidus*, *Cytisus præcox*, *Ceanothus Veitchii*, *Cornus Mas variegata*, *Correa magnifica*, *C. alba*, *C. ventricosa*, *C. curiosa*, *C. cardinalis*, *Daphne Genkwa*, *D. blagayana*, *Edgeworthia chrysantha*, *Erica australis* and six other species, *Grevillea sulphurea*, *Gaudia*

WORKERS AMONG THE FLOWERS.

MAJOR C. C. HURST.

HORTICULTURE of to-day owes not a little to the investigations of scientific men, who may legitimately be regarded as workers among the flowers. It is doubtful whether the average horticulturist realises the immense amount of sound investigation into plant-life that Major C. C. Hurst, whose portrait it is a pleasure to publish in this issue, has done. As Director of the Burbage Experimental Station at Hinckley, Leicestershire, Major Hurst had charge last year, and has charge this year, of the National Sweet Pea Society's trials, and we think it appropriate to give some particulars concerning him in this our Special Sweet Pea Number.

Apart from his work among Sweet Peas, evidence of which is clearly set forth in the admirable paper read by him at the National Sweet Pea Society's Conference last year, and now published in the Society's "Annual," Major Hurst has done a vast amount of work among flowers. Of these, mention may be made of Orchids, Roses, Antirrhinums, Rhododendrons, Berberises and Daffodils, while the more utilitarian fruits and vegetables have not escaped his active attention. Indeed, it is to memoirs and articles of his which have appeared from time to time in the publications issued by the Royal Horticultural Society, Linnean Society, Royal Society and the British Association, that we are indebted for much new information about plant and animal life in general. We mention animal-life because this has been almost, if not quite, as deeply investigated by him. With Mr. R. A. Rolfe of Kew, Major Hurst is responsible for the Orchid Stud Book, the only one of its kind ever compiled.

In other directions our worker among the flowers has distinguished himself. He is a Member of the Advisory Council on Horse-breeding to the Board of Agriculture and Scientific Adviser to its Standing Committee, a Fellow of the Linnean Society, Member of the Scientific Committee of the Royal Horticultural Society, and Correspondent of the Carnegie Institute of Experimental Evolution, Washington, U.S.A. Before devoting himself entirely to scientific research, Major Hurst served in the 4th and 5th Battalions of the Leicestershire Regiment, and was for ten years on the Staff as an Instructor of Signalling, and Brigade and Divisional Signalling Officer. He retired with the rank of Major, and is now in the Reserve of Officers. That Peace will enable him to carry on his valuable work of investigation into plant-life is the earnest desire of all who are privileged to know him.

FORTHCOMING EVENTS

- February 3.—National Chrysanthemum Society's Annual Meeting.
- February 4.—Royal Horticultural Society's Exhibition and Meeting. Lecture at 3 p.m. by Mr. C. F. Ball on "Plant-hunting in Bulgaria." Horticultural Club's Annual Meeting and Dinner. Scottish Horticultural Association's Meeting.
- February 7.—Royal Gardeners' Orphan Fund Annual Meeting and Election of Orphans at Simpson's Restaurant, Strand, at 3 p.m.
- February 10.—United Horticultural Benefit and Provident Society's Meeting.

GARDENING ACROSTICS.

BELOW will be found acrostic No. 8, which finishes the series. The solution to No. 7, which appeared last week, will be given in our next issue, and the solution to No. 8, together with the names of those who have correctly solved Nos. 7 and 8, and the names of the prize-winners, will appear in our issue dated February 15.

DOUBLE ACROSTIC No. 8.

My firsts.—The surnames of two men who have added much to our knowledge of plant biology.

My lasts.—Their "special line."

NOTE.—Arrange as usual; then reverse the letters of the evens.

1. The initials of the member of the Elephant's Trunk family that has the most characteristic seed-vessels.
2. The maker of Versailles.
3. I end in smoke.

SOLVERS OF ACROSTIC No. 5.

ALTHOUGH a number of readers succeeded in getting most of the points right in No. 5, no one sent in a correct solution as published last week. We would remind readers that prizes will be awarded to those who correctly solve the greatest number.

** The names of those who have correctly solved No. 6 will be given next week.

PRIZES FOR THE BEST ROCK GARDENS.

To further stimulate the interest that is now being taken in rock gardens, the Proprietors of THE GARDEN offer the following prizes for three photographs of a rock garden, or portions of a rock garden:

- First Prize : Five Guineas, or a Silver Cup of that value.
- Second prize : Two Guineas, or Books of that value.
- Third prize : One Guinea.

The competition is open only to the actual owner of the rock garden, or to his or her gardener. The object is to encourage good rock gardening, and preference will, therefore, be given to those rock gardens which show originality in design, and where the plants depicted are well grown. It should be distinctly understood that awards will be made to the best rock gardens, and not necessarily to the best photographs. The photographs need not be taken by the competitor, who must, however, in such cases have the written consent of the photographer for their reproduction in THE GARDEN.

For rules governing the competition will readers please see our issue dated February 4.

All photographs must be sent to arrive at THE GARDEN Offices, 29, Tavistock Street, Strand, W.C., not later than June 1, 1913.

SOME FUTURES FOR THE SWEET PEA.

IT would be an easier task to write about the importunities of editors than about Sweet Peas. I would certainly have something to say then, both from the victim's and also from the paper's point of view. A successful importunate editor must be worth his weight in gold provided only he importunes the right people. I feel badly equipped to write just now on Sweet Peas. For one thing, I did not visit any Sweet Pea shows last year except our own local one at Whitechurch (Salop) and a particularly pleasing "at home exhibition" of Dr. Phillips at Malpas. Again, the catalogues and books devoted either wholly or in part to this one flower are legion, not to mention the many notes and articles in the papers, so that it is almost beyond the bounds of human possibility to say anything new about them. And yet I have promised to write, and I do not want to take away from the weight of the Editor, so I feel a little nervous in putting pen to paper to record these few random thoughts about the future.

Bush Sweet Peas.—I used to grow these once upon a time, and I found them most useful for supplying the greenery in my Sweet Pea vases. It has since occurred to me that this 2-foot to 3-foot type might be developed, and that if good shaped and many flowers could be put upon them, they would be very valuable for border decoration.

Scent.—I should like to see a class for fragrant varieties introduced at some shows. I think I am quite right in saying that in the evolution of the modern Sweet Pea fragrance has suffered somewhat severely. Mother of Pearl is my ideal in this respect. You can always smell it when you pass it by in the garden. Lead me blindfolded down a row of yard patches of different kinds, and I would always know when I came to it. Now, why not a class for fragrance? It wants encouragement.

Trained Sweet Peas.—

Schedule-makers are doubtless on the look-out for new ideas. I am sure the late chairman of our committee must be sighing for new worlds to conquer. I expect he saw some wonderful examples of trained Chrysanthemums in Paris, as I did at Liverpool last autumn. Well, why not try if something in this way could not be done with the Sweet Pea? The results might be stiff, but they would be, like the Chrysanthemum plants, a triumph over difficulties. Here is my suggestion: Class so-and-so, for the best balloon-trained plant (or plants) of Sweet Peas growing in an 8-inch or 10-inch pot.

Sweet Pea "At Homes."—It struck me that this is a capital idea, and one that might be carried out by a good many people. It would provide an object for high-class cultivation, and also give much pleasure to one's friends and acquaintances. A mass of one flower is always effective, and it is surprising what an interest the comparing of one sort with another is when a good many are brought to one's notice. Two friends might join forces in growing and share the expenses of the day very well. The requisites are a tent and good staging; or a large room would do instead of the former. A band, or music of some description, would, of course, be an additional attraction.

There is nothing more stimulating to the true lover of a flower than to see from time to time attainments to which he, too, one day hopes to aspire.

JOSEPH JACOB.

SWEET PEA ERIC HARVEY.

It is for table decoration and garden effect that this comparatively new variety is especially commended. The flowers are of average size, nicely waved and gracefully arranged on the flower-stems. In colour, the back of the standard is of a pleasing soft rose, while the front view presents a Picotee marking on a white ground. This variety, raised a few years ago by Mr. W. J. Unwin, Histon, Cambs. is now quite fixed, and is certainly one of the best garden Sweet Peas of recent introduction.

SWEET PEAS AS BEDDING PLANTS.

DURING recent years the cultivation of Sweet Peas for garden decoration has been carried out in many ways, and in some a great deal of ingenuity has been displayed. With such a free-flowering and easily-grown annual it is not difficult to understand the desire of the amateur to put it to as many uses as possible; but we do not ever remember seeing it used as a bedding plant. We refer, of course, to the Sweet Pea proper, and not the Cupid forms of it. When visiting a market-garden establishment in a country district last summer, we were surprised to come across a large bed of Sweet Peas that were grown primarily for providing cut flowers, but which had, by some means or other escaped being staked. The result was that the plants had become procumbent and the growths had intertwined, so that the whole made one glorious bed of fragrant, delicately-poised blossoms. No doubt Sweet Pea enthusiasts would term this bad cultivation, but with this we should not agree. It is unconventional, but the effect was most pleasing. The flowers were of good size and quality, and the illustration on page 57 will give a slight idea of the effect. The owner

SWEET PEA ERIC HARVEY, A BEAUTIFUL VARIETY FOR GARDEN AND HOUSE DECORATION.

Later in the day, when the "at home" is over, the smaller people of the neighbourhood might be invited to look round, and I am sure they would appreciate the sight.

Local Shows.—We have had one at Whitechurch for two years, and we are going to have a third this year. My experience tells me two things: First, that there must be a hard-and-fast radius line to ensure the competition being truly local; and, secondly, that there should be, if at all possible, one open class with sufficiently valuable prizes to attract a few of the tip-top growers like Mr. T. Jones, Mr. Usher, Mr. Stevenson and Mr. Prophet

informed us that immense quantities of good blooms had been cut from the bed, and that the plants had been in good and floriferous condition for many weeks.

Those who have large lawn beds to fill, and who are looking out for a cheap and unique method of doing so, might well sow or plant them with Sweet Peas on the lines suggested in the illustration. If desired, a good pillar could be formed as a centre-piece by providing supports in the form of sticks or Simplicitas Netting for the plants there to scramble over. The only drawback to growing Sweet Peas in beds in this way is the difficulty

in getting at all the newly-formed seed pods to remove them, an essential point where continuity of flowering is desired; but this can be overcome with a little care. The bed illustrated was about nine feet wide, and, by carefully placing one foot between the haulm, the centre plants could be reached in comfort.

SWEET PEAS REVERTING TO THE WILD TYPE.

THOSE who had the privilege of hearing Major Hurst's interesting paper at the annual conference of the National Sweet Pea Society on rogues in Sweet Peas must have been impressed by the fact that the greater knowledge of Mendelism as applied to the hybridisation of Sweet Peas has been of the greatest assistance, not only to the actual raiser, but has provided a satisfactory explanation of many curious and seemingly inexplicable facts that have occurred in many gardens.

Some readers may recall a discussion a few years ago concerning a statement that seeds of Sweet Peas purchased from one of our best known English seedsmen had reverted to the wild purple bicolor in Sicily and Madeira.

One of these cases was particularly interesting to the writer, as it happened in his mother's garden at Taormina in Sicily. Although this island is the home of the wild Sweet Pea, our modern, highly-cultivated production was there practically unknown at that time. With up-to-date methods of cultivation and the natural climatic advantages these plants from imported seed grew to great perfection, producing particularly fine blooms, and were the object of much admiration and curiosity in the surrounding neighbourhood. Therefore, great must have been the disappointment of the owner, having carefully saved the seeds of each variety separately, to find, the following year, haulm and growth giving promise of equally good results, that the early blooms (the wild Pea of Sicily blooms earlier than our Pea) were merely a slightly-improved form of the purple bicolor. Irritated at the disappointment, she did not wait for any more to blossom, but ordered them all to be pulled up. Thus did she destroy what might have been not only the elucidation of the mystery, but further possible proofs of the working of the theory of Mendelism, and the production of new varieties had she saved the seeds of these plants.

Many of our experts were consulted, and the subject was referred to at the Sweet Pea Conference in 1910, but it was considered hardly credible, and the general feeling was either that the statement was inaccurate or the gardener was dishonest. As may be well understood, these explanations (!) were received with natural indignation, and the subject has since been carefully avoided in the family.

Major Hurst's reply to Mr. Sydenham's question, why Sweet Peas, when saved in Sicily or Madeira, reverted to the wild purple, was awaited with great interest by those who had heard of similar incidents in those countries. His lucid explanation was a

real clearing up of the mystery. The wild Sweet Pea, being a native of Sicily, was evidently visited by some insect (possibly the leaf-cutting bee, very common in those parts, which carried the pollen from the wild to the cultivated varieties, and, the old purple bicolor being dominant over all other colours, it was only natural that all flowers thus cross-fertilised should produce the purple bicolor.

Langford, Bristol.

VERNON T. HILL

RECENT IMPROVEMENTS IN SWEET PEAS.

AT this season the Sweet Pea lover usually reviews the past and wonders what the future has in store. We are told by some that there are very few distinct novelties, and that there is very little advance from year to year. What greater advance could we have than in scarlets? Two years ago we had no scarlets with

had in most districts, and this may delay the arrival of some of them. The following are a few I have seen: King White—This is a wonder for size and purity. It is quite as large as Melba, has four blooms on nearly every stem, and often five. The blue Picotee edge is coming, both on white and cream grounds. These, I have been told, have taken some time to fix. Both will be very much in demand when offered. A Stirling Stout with the size and vigour of King White will make some of the keen hearts flutter when they grow it for exhibition. A large Mid Blue Spencer proves that the Lavender blood is not all exhausted yet. I saw one in July last, and it was a beauty—pure perfection.

The duplex varieties have quite as many admirers as opponents. There are some lovely stocks of these about the country. There is one duplex that has never given less than two double flowers, often three, and sometimes all four on a stem. When the raisers are able to offer it, the marketmen and those who grow for cutting will be pleased

A BED OF UNSTACKED SWEET PEAS, SHOWING HOW THESE FLOWERS MIGHT BE USED FOR LARGE DECORATIVE BEDS.

true Spencer form and growth; now there are several offered for sale. I think this class will gain in favour, as most of them improve after cutting, while the crimson shades soon lose colour. It is almost impossible to send or carry the latter in boxes for any length of time and find them of good colour.

The first of the waved type, Countess Spencer, is losing ground. It cannot compete with Hercules or Elfrida Pearson. Again, who would have said two years ago that Helen Lewis would so soon drop out of cultivation? John Ingman will have a struggle to hold its own in 1913, as Rosabelle will be a favourite. It is much more effective, both in the garden and on the table. The salmon shades are improving, both in size and vigour, and the same applies to most of the other colours. We cannot expect to see such distinct novelties every year as Mrs. W. J. Unwin, Charles Foster and May Campbell.

That there are still some lovely varieties to come I am convinced. The seed harvest of 1912 was

with it. I hope all the Sweet Pea lovers will have a good season. ANDREW IRELAND.

HOW I GREW SWEET PEAS AT SUTTON GREEN.

IN connection with Sweet Peas there is nothing, to my mind, so interesting as growing different varieties for trial, and the person who has under his care such trials as those organised by the National Sweet Pea Society is to be envied by all Sweet Pea lovers. There are certainly few who have such an opportunity of becoming so well acquainted with the best novelties of the leading raisers previous to their being placed on the market. But such privileges are not without their responsibilities, for one can understand that a failure or two through the ravages of mice or disease or bad germination are not pleasant memories. There is also the grower who has one or more stocks

badly mixed, and who promenades up and down the rows saying that he cannot understand it at all, as they are quite fixed at home.

The germination at Sutton Green last year was remarkably good. Out of over two thousand one hundred seeds sown, over 93 per cent. germinated; but, of course, the seeds were all specially picked. All the same, a good deal was due to the potting material, which consisted of decayed turf and sandy soil containing little humus. The plants were strong and healthy, but hard; not, as one often sees, strong and sappy. These hardy seedlings can be planted out sooner and will not be so adverse to the changed conditions, and for this reason it is advisable to limit the richness of your potting material and pay more attention to the drainage. Ventilating freely in mild weather and gradual hardening off must not be overlooked. The method of cultivating the soil which was

COLOURED PLATE.

PLATE 1464.

FOUR GOOD SWEET PEAS.

THE four Sweet Peas shown in the coloured plate presented with this issue represent some of the best that have been introduced during the last few years. Each has some special merit to recommend it to those who are interested in Sweet Peas, and all are good for garden decoration, for cutting, or for exhibition. Walter P. Wright and Leslie Imber were both put into commerce by the raiser, Mr. W. J. Unwin of Histon, Cambs. The first named is regarded by many as the finest of its class, the large, pale lavender flowers being exceedingly pretty and freely produced on long, stout stems. Leslie Imber is worth growing if only

invariably produces four on a stem under good cultivation. It is of strong, vigorous growth.

Red Star was raised by Messrs. Dobbie and Co. of Edinburgh, and sent out by them last year. In 1911 it secured the distinction of an award of merit from the National Sweet Pea Society. It is a very deep rich scarlet self, and last year produced more stems with four flowers than any other scarlet variety we had.

THE ROSE GARDEN.

SOME OF THE NEWER DECORATIVE ROSES.

HYBRID TEAS.

(Continued from page 45.)

Lady Greenall (A. Dickson and Sons, 1911).—

I referred to this under the exhibition varieties, but it is really as a garden Rose that it will be most useful. There is no reason why our garden Roses should not be as exquisite in shape as the exhibition varieties, provided they answer our other requirements. It is not so very long ago that the term "garden Rose" was almost synonymous with a Rose of indifferent shape; but now we are getting our garden Roses as perfect in shape (possibly smaller) as their exhibition cousins, and the Rose under notice is an excellent example of what I mean. The flowers are of beautiful shape. It would be hardly fair to call them of medium size, but they are not very large, with, however, a beautiful pointed centre, and good outside guard-petals that reflex. Colour, creamy white ground, suffused with saffron orange. It has a delicious Tea scent, and is quite free-flowering and a good grower. It is a Rose of distinction, and will be much used for bedding purposes when better known. I think I am correct in saying it was one of the most admired of the newer Roses in my garden last summer.

Lady Margaret Boscawen (Alex.

Dickson and Sons, 1911).—Another Newtownards variety of excellent garden habit. It makes a very pretty button-hole even in the fully-expanded flower, as it is not too large for that purpose and of very pretty shape. The colour is soft

blush, with a slight suggestion of fawn as the under colour; strongly Tea perfumed and holds its flowers erect. Not quite mildew-proof, but a good and pleasing Rose all the same, and one that will find favour with many.

Lady Pirrie (Hugh Dickson, Limited, 1910).—

If this Rose had only a few more petals, it would be near perfection. There is no gainsaying the beautiful combination of colour, especially in the bud and half-opened flower stage. I will not attempt to do it justice—it has to be grown to be fully appreciated; but the outside of the petals might be termed of a coppery salmon, and the inside fawn and apricot. The bud is a good long one, and makes a button-hole that will take a lot of beating. The foliage and habit of the plant

A LITTLE-KNOWN AUSTRALIAN DAISY-BUSH, OLEARIA MYRSINOIDES.

found from experience to be the most satisfactory should prove interesting to those Sweet Pea lovers having a sandy soil, the difficulty being, of course, to get the plants to last during dry spells. As soon as possible in October trenches 2 feet 6 inches wide and 1 foot deep were taken out and the soil placed between the trenches, there being ample room, as from the centre of one trench to the next 6 feet 6 inches was allowed. The bottom of the trench was deeply forked, and bullock-manure and about three pounds of bone-meal to a 20 yards run worked well in. The trenches were then left for the frost to work on the soil until February, when the top spit was replaced, a sprinkling of soot being added. Another point which must not be overlooked on sandy soil is deep and firm planting. HARRY L. POSTER.

for the sake of its unique colour. Unfortunately, this is not well shown in the coloured plate. In reality the standard is medium blue and the wings a much deeper shade of that colour.

In the variety Edith Taylor we have a Sweet Pea that is quite distinct and one that is regarded by many as indispensable. It was raised by Mr. Robert Holmes of Tuckwood Farm, Norwich, and put into commerce by him last year. Mr. W. J. Leak, vice-chairman of the National Sweet Pea Society, has very kindly sent us the following description of it: "A most pleasing shade of deep rosy cerise or old rose. Quite distinct from any other variety. It has the advantage that the colour intensifies in the sun, whereas all others of a similar shade burn badly. The flowers are large, of fine form and beautifully waved, and the plant

Four good Sweet Peas

- 1. Walter P. Wright.
- 2. Feshe Imber.
- 3. Edith Taylor.
- 4. Red Star.

are good, and it will become very popular, especially for decorative purposes indoors. It is undoubtedly one of the most beautiful Roses that the Belmont firm have given us. It was awarded the gold medal of the National Rose Society at the Royal Botanic Show in 1909, but was not sent out till the following year.

Lady Reay (Messrs. B. R. Cant and Sons, 1911).—This is another button-hole variety, and at the same time free-flowering enough for a bedder, although possibly the majority would choose a larger-flowered variety. The colour is bluish pink in the centre, shading off to mother-of-pearl white. My plants of it—and I had five—were always in flower last summer; but it might with advantage be a stronger grower. It is scented, and can be obtained at the reasonable price of 1s. 6d.

Leslie Holland (Hugh Dickson, 1911).—Although best known as an exhibition variety, I am inclined to think that at the moment this is the best bedding variety of its colour. We have long wanted a real good scarlet-crimson garden Rose. J. B. Clark and Hugh Dickson, both from this firm, will still be grown, the one as a pillar or semi-climber, the other as an exhibition Rose and as a fine standard; but for one of a set of, say, a dozen beds, they were both almost impossible by reason of their growth. Leslie Holland does not sin in that respect, and is, therefore, a much better bedder than either. It is a good grower, but not too vigorous, rarely throwing shoots more than 3 feet. I should say 2 feet is about the average height of the plant; free-flowering and fragrant.

Little Dorrit (Paul and Son, 1912).—Although figuring in most catalogues as a Tea, this Rose, when exhibited by the raisers at the autumn show of the National Rose Society, where it was awarded a silver medal in the new seedling Rose class, was termed by them a Hybrid Tea, and I should say correctly so. It is of almost China habit, and as seen growing in the Cheshunt nurseries of the firm was very free-flowering and a beautiful Rose, with something of the colour associated with Hugo Roller, only deeper. It will appeal to all as a most effective dwarf bedder. The centre flower of the spray is very prominent, of excellent shape. The colour is lemon yellow, splashed and edged with deep carmine rose that gives a coppery effect. Altogether a charming variety.

Southampton. HERBERT E. MOLYNEUX
(To be continued.)

TREES AND SHRUBS.

A BEAUTIFUL DAISY BUSH.

(OLEFARIA MYRSINOIDES.)

THIS graceful and evergreen species has long been in cultivation, but is still a somewhat rare plant in gardens. It has the habit of forming long, arching or trailing growths, densely clothed with rich dark green, wavy leaves, and is covered in all its upper parts with hundreds of Daisy-like flower-heads during the month of June. Each head is 1 inch in diameter, the ray

of a rather poor or sandy nature is the best, although by no means absolutely essential, providing other conditions are favourable.

It is a common plant in Tasmania, and also occurs locally in Victoria and New South Wales, growing in poor, sandy soil or rocky, barren, scrubby places where little else can exist. In common with the majority of the species, it does not stand exposure to severe weather to any extent without suffering, and in selecting a suitable position in which to plant, shelter from cold, cutting winds should be taken into consideration, also bearing in mind that a stiff heavy soil or wet position is fatal to success. The hardest and, for general purposes, the best species of the genus is *O. Hastii*, a fairly common plant, especially in the South. Its merit lies in its floriferous and evergreen habit and in being a most useful shrub for town gardens where the soil is light and well drained.

C. P. RAFFILL.

THE SWAMP HONEYSUCKLE.

THE hardy Azaleas or Swamp Honeysuckles lend a touch of beauty to the shrubbery and woodland that no other subject can impart. The pleasing tones of colour created by masses of yellow, orange, fiery reds and delicate pinks are so beautiful in May and early June that they quite baffle description. Moreover, in the fall of the year the foliage assumes autumnal tints of bronze, purple, and even crimson hue.

In a general way these beautiful shrubs are spoken of as Ghent Azaleas, although in reality they have their origin in the bogs and uplands of North America. The Californian species, *A. occidentalis*, produces bunches of fragrant white flowers a little later in the year than most others, and this species is certainly one of the most charming in autumn tints. The pure white Ghent Azalea named Anthony Waterer is one of the most

popular, while those with double Hose-in-hose flowers, called the narcissiflora group, are now widely grown. Azalea molis, from Japan, with its host of varieties in salmon red and orange tones, are likewise hardy, and being dwarf are best suited for planting in the foreground.

This is quite a good season for the planting of Azaleas. While it is true that they are peat-loving shrubs, it should not be overlooked that they do quite well in loam, providing it is deficient in lime. The illustration on the next page shows the spring effect created by well-grown bushes.

THE NEW ROSE MRS. CHARLES RUSSELL, WHICH GAINED AN AWARD OF MERIT AT THE ROYAL HORTICULTURAL SOCIETY'S SHOW ON JANUARY 21. (See page 60.)

florets being pure white, those of the disc being yellow and fading with age to brown. When seen at its best it is a really effective and valuable plant, and is well suited for trailing over a large rock or stones in the rockery. It is also useful for the front of the shrub border.

The largest plant with which I am acquainted is some 3 feet or 4 feet high and about the same in diameter, and is about eight years old from a cutting. A well-drained and sunny position, sheltered from the north and east, is the most suitable for this plant, and a compost which is

SEASONABLE NOTES ON SWEET PEAS.

Multiplication of Sweet Pea Names.—In the "Sweet Pea Annual," among other matter of more or less general interest, Mr. Lester Morse of Santa Clara, California, gives his "Impressions of the Sweet Pea Show of 1912." These are mostly exceedingly flattering to the grower at home, and it cannot be doubted that Mr. Morse will be written down an excellent fellow; whereas, if he had ventured to be critical, as he could easily have been, our thoughts of him would have been the reverse of complimentary. The most interesting portion of his remarks is that in which he alludes to the multiplication of names in Sweet Peas. Mr. Morse says: "I was greatly impressed, and annoyed, when I came to my note-taking, to discover a hopeless confusion of new names. A hundred varieties I thought I easily recognised were shown under names I have never heard of,

so closely similar that it would demand a wonderful power of imagination to discover the difference. They have no opportunity of ascertaining which varieties are distinct, except the personal experience which they cannot afford to give. I do not mean that they particularly begrudge the cash, but they do emphatically object to the waste of space which is entailed when one variety is unknowingly grown under a multiplicity of names. It will be said that they ought to go to the National Society's trials, but that is absurd. Not one person in fifty can do this, and many of them would not if they could.

The fact is that in the old days they looked to the National Sweet Pea Society to keep them on the right track; but they do not do that now, because they find that scarcely anything useful is done in this direction by that powerful body. Mr. Morse expresses pity for the committee which is set the task of putting things right; but that task will have to be faced. A committee must be appointed, consisting of amateurs of ripe know-

is done to remedy this, the Sweet Pea, and also those who make it their business to grow seeds for sale, are bound to suffer.—Ed.]

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Narcissus minicycla.—An early-flowering hybrid between *N. minimus* and *N. cyclamineus*, in which almost intermediate characters between the two species have been established. The taller growth is that of *N. cyclamineus*; the colour, the reflexing brim of the crown and its many divisions are characteristics easily traceable to the first-named parent. The Cyclamen-flowered character of the perianth segments, which is so marked a feature of *N. cyclamineus*, is apparently lost in the hybrid, the perianth segments being almost at right angles with the crown. The plants first flowered when four years old, and as shown were 4 inches to 5 inches high. In all probability a taller habit may yet be forthcoming. As an early variety it will be welcome in the alpine-house. From Mr. F. Herbert Chapman, Rye.

Cyclamen persicum St. George.—A deep salmon-coloured variety with crimson base to the petals. In this respect the variety is not superior to other salmon-coloured forms. The great attraction is in the handsome, well-marked leaves, some marbled and veined with white, others heavily bordered. The variety appears to reproduce these variations in large degree from seeds. From the St. George's Nursery Company, Harlington, Middlesex.

Rose Mrs. Charles Russell.—A variety with a gloriously rich perfume and fine form. Of its true colour we are not in a position to determine, the handsome vase of flowers gaining the award only reaching England from America the day prior to the last meeting. Those flowers having been cut some ten days from the plants, and probably cold-stored at once, would account for the non-descript colour tone—pale Pickling Cabbage red—as presented. The 2½-foot-long stems and highly-built flowers were of the usual American type, and which we in England might well imitate. Could we but also imitate America's sun during the winter season. The whole secret of such productions are sunlight and sunheat. (See page 59.) From Mr. W. A. Manda, St. Albans.

NEW ORCHIDS.

A first-class certificate was granted to M. Firmin Lambreau of Brussels for a magnificent variety of *Cattleya* Enid named Firmin Lambreau. Awards of merit were made to the following: *Lalio-Cattleya Firmini* ardens, shown by Firmini Lambreau; *Cœlogyne intermedia*, shown by Messrs. James Cypher and Sons; *Odontioda Madeline* Prince of Orange, from Mrs. C. J. Phillips of Sevenoaks; *Sophro-Cattleya Orchid Dene*, from E. H. Davidson, Twyford; and *Odontoglossum Aureworthii* Goodson's variety, from Mrs. H. S. Goodson of Putney.

The foregoing awards were made by the Royal Horticultural Society on the occasion of the fortnightly meeting held on January 21.

THE BEAUTIFUL SWAMP HONEYSUCKLE OR HARDY AZALEA. THE SHRUBS MAY BE PLANTED NOW. (See page 59.)

and frequently one variety bore four to six names. I thought last year that Margaret Madison was absolutely new, but I found it here under seven names. A variety we had named Veiled Lady, but which we will not send out, I found here with two other names, i.e., The Abbot and Birdbrook. The Earl Spencer shade must have had quadruple twins and the Scarlet Spencers surely led the bunch. I pity the committee that attempts to straighten out the nomenclature."

I am, of course, sorry that Mr. Morse should be "annoyed" at anything that he found in this country; but his annoyance is not nearly as important as that of hundreds, probably thousands, of amateur Sweet Pea-growers at home. Purchasers of Sweet Peas are becoming disgusted with the descriptions in catalogues, and place little reliance upon them. They find different names, different descriptions, and growing one, two, three, or, according to Mr. Morse, anything up to seven, may find all the flowers identical or

ledge, and it must be given the widest powers to bracket varieties which are identical or so close that it is impossible for the ordinary man or woman to distinguish them. No trade grower must be on this body, because, no matter how conscientiously the committee did its duties, the decisions would not prove acceptable to the Sweet Pea world.

It is the amateur lovers of the Sweet Pea who keep the society going, and who, incidentally, make it worth the while of the trade to support that society in so generous a manner, and they are therefore entitled to be far more carefully considered than is the case at present. The "Sweet Pea Annual" is good, but it is not worth 5s. unless it contains information which cannot be got anywhere else and which is perfectly reliable. AMEINON.

{Although we publish the above, it does not mean that we necessarily agree with all the statements made by our correspondent. We do, however, endorse his remarks regarding the multiplication of names. Unless something very drastic

GARDENING FOR BEGINNERS.

HOW TO RAISE EARLY VEGETABLES IN FRAMES.

By the use of cold frames, frames placed on hot-beds and those heated by hot-water pipes, several kinds of vegetables may be brought to maturity—that is, to a condition suitable for cooking—very early in the year. Such produce is highly appreciated. By the same means other kinds of vegetables may be considerably forwarded in growth. This is done by simply sowing the seeds in boxes, pots or beds in the frames, and then by carefully nursing the resultant seedlings under glass while the cold weather prevails, so that there will be a nice stock of sturdy plants fit to put out directly the weather and the soil in the garden are suitable. A great deal may be done in this direction by the use of one frame only.

Early Potatoes may be dealt with at once. In Fig. A, No. 1 shows how the seed tubers must be planted in a frame in a bed of good soil, put in to a depth of 1 foot. The surface of the soil (No. 2) should be 1 foot from the glass. If the frame is a very deep one, littery manure, tree leaves, or both, mixed, may be put in to fill up, the soil being placed on the bed. The latter will soon become warm and hasten the growth of the Potatoes. Wooden frames, as well as brick ones, may be used for this purpose. No. 3 shows a good seed tuber bearing one strong sprout only. Such generally produce a crop of fine eating tubers and few small ones. No. 4 is a tuber quite unsuitable for planting either in frames or in the open border. A succession of Potatoes may be assured by planting a few tubers at intervals of twenty-one days. Some of the tubers may be brought on by placing them in boxes and surrounding them with light soil, as shown at No. 5. The sprouts will grow and roots form, as shown at No. 6. These forwarded tubers should be carefully planted, when the growth will continue and young tubers soon form. I may say here that all frames should be covered with mats or straw on frosty nights; but it is essential to success that the maximum amount of light be

EARLY CROPS OF POTATOES CAN BE EASILY RAISED IN FRAMES.

admitted to all young vegetables, also fresh air when the weather is mild enough. No. 7 shows how to put the drainage material in a 12-inch pot, or in a box for seeds of Cauliflowers, Cabbages, Brussels Sprouts, Leeks, Lettuces, Tomatoes, Celery, &c. The seeds must be sown in the finer compost (No. 8). No. 9 depicts a young seedling Tomato potted singly in a 3-inch pot. These plants do well on a mild hot-bed.

Turnips, Radishes and Carrots should be sown in shallow drills in cold frames, as shown at Nos. 1,

2 and 3 in Fig. B; or broadcast, as depicted in Nos. 4 and 5. Long, narrow frames such as these are very suitable for seedlings of Cauliflowers, Cabbages, Celery, Brussels Sprouts, Lettuces, &c., to be transplanted from the seedling-boxes, as shown at No. 6. A small wooden frame of this kind will accommodate many hundreds of seedlings in boxes. Such a frame may have a bed made up in it and Carrots grown, as shown at No. 7. Ventilate freely when the weather is not frosty. It is a fact that young Carrots form larger roots when the frame is removed after they are well established. This may be done late in March, exposing the crop to the wind. Early-maturing varieties of vegetables must be selected, of course; Turnips with small tops, as shown at No. 8; and Carrots of the French or English Horn types, as depicted at No. 9. No. 10 shows a seedling Cauliflower ready for transplanting; No. 11, the same ready for a second shift; and No. 12, the same fit to plant in a deeper frame, or in an open, sheltered border. Nos. 13 and 14 show how Leeks are strengthened by transplanting; and No. 15, a stocky Lettuce raised in a cold frame. G. G.

LETTUCE AND OTHER KINDS OF PLANTS FOR THE OPEN GARDEN MAY BE RAISED IN FRAMES AS SHOWN.

CLEANING THE LEAVES OF PLANTS IN HOUSES.

THERE is no time more suitable than the present for cleansing the leaves of various kinds of greenhouse and stove plants. In summer-time many kinds of foliage plants are freely syringed every week. This work prevents sediment lodging on the leaves; but in winter-time there is not much syringing done, and as there is more smoke from chimneys around, sediment accumulates on the leaves of the plants. Scale and other insect pests must be got rid of, and to this end we should use warm soapy water and a clean sponge.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Sweet Peas.—All ground for Sweet Peas should be prepared at once. Good deep trenching is essential, with a liberal supply of manure in the lower spits. Stations for clumps in borders or on the verges of lawns may with advantage have the soil renewed, thus ensuring good healthy growth. Where the grower depends on spring sowing, no time should now be lost, choosing those varieties which suit the individual requirements best.

Climbers, such as Vitis, Ivies, Honeysuckles, Clematises, Wistarias and wickuraiana Roses, whether growing on poles, arches, pergolas or on the house, should now be pruned. In some instances they may need tying or nailing in; in others a trimming up may be all that is necessary, taking off all the unsightly hanging growths of last season that are unnecessary for the proper furnishing of the structure they are on.

Pyrus japonica, now nicely in bloom in sheltered positions, should, if necessary, be cut back after the period of flowering is over; but only where the area to be covered is restricted. Plants trained on the houses must, of course, be kept spurred in, or they soon become rather unsightly.

The Pleasure Grounds.

Pruning.—Though I prefer pruning shrubberies rather later in the season to avoid the danger of severe frost, which at times kills the shrubs back, yet, where there is a great deal to do, the work must perforce be pushed forward, commencing with those in a sheltered position.

Digging.—Naturally, after pruning, the shrubberies should be dug whenever possible; and, needless to mention, if plenty of leaves are dug in, the leaf-soil will keep the plants in a good growing condition, it being the most natural form of manure and certainly all that can be afforded in many instances.

Plants Under Glass.

Liliums.—By this date all imported bulbs should be to hand and potted forthwith. For general decorative purposes single bulbs in pots are very useful; but for use as specimen plants in the conservatory or for cut-flower purposes, three to five may be potted in 8½-inch or 9½-inch pots.

Amaryllis.—Bulbs that flowered early last season will, on examination, be found to be pushing their flower-spikes, and should be removed to a house with an intermediate temperature. Very little water is necessary till the flower-spikes are well advanced, or the foliage may come away quickly, and thus rob the flower both of nourishment and good appearance.

Clarkia elegans.—Autumn-sown plants that have been wintered in 3-inch pots should now be potted on, still keeping them in a very cool position; also a further sowing should now be made for succession, these plants being extremely useful both in pots and for cut flowers.

Mignonette also should be potted into its flowering pots, either 4½-inch or 6-inch. Firm potting is very necessary to keep the plants dwarf and to get good flower-spikes. Where sown straight into their flowering pots, they may now be showing flower. If bushy enough, feed a little; if not, pinch the points out. This will induce them to break and make better plants.

The Kitchen Garden.

Peas.—Good batches of dwarf early varieties should be sown as soon as the ground is in a fit condition, preferably on a warm border, Laxtonian and Little Marvel being excellent varieties.

Broad Beans.—These also may be sown at once to succeed those sown outdoors in the late autumn. These latter, being pretty forward, may have the soil drawn up to them a little to preserve them from the frost if it is likely to be severe.

Parsley.—In cold districts this does not always winter well, and as that sown in frames runs to seed early, a sowing should now be made in boxes as a succession. This, if pricked off as soon as ready on to a warm border, will soon get away, and be found ready for use much earlier than that sown in the open a little later on.

Celery.—For very early work a sowing of one of the white varieties should be made in boxes or on a hot-bed, pricking it off as soon as large enough to handle.

Leeks.—For exhibition purposes early sowing of Leeks is quite essential, and these also may be sown in boxes or even singly in 2½-inch pots, pricking or potting off in the first case as soon as necessary, and in the latter potting on into 3-inch or 4½-inch pots. A temperature of 50° to 55°, with occasional sprayings overhead to assist germination, will suit them nicely.

Fruits Under Glass.

Early Peaches.—Whether these are pot or planted-out trees, as soon as nicely in bloom they should be fertilised by means of a rabbit's tail or some other pollen-distributing appliance, preferably about midday, after a little air has been put on to ensure the pollen becoming dry. This must be repeated every day or two till the last flowers have opened, and it invariably ensures a good set of fruit.

Hardy Fruit.

Spraying.—This has become one of the essentials of fruit cultivation, and the month of February is probably the best time to do it. To get the very best results, it is work that must not be performed in a haphazard manner, but every branch and crevice must be well wetted to ensure all the eggs or larvae of insects being killed.

Mussel Scale.—The ordinary caustic alkali spray I have not found to kill the above, and as it is a most insidious pest when it once gets hold, great pains should be taken to try to eradicate it. Spraying with a strong paraffin emulsion will often loosen it, but the trees should be thoroughly gone over once or twice with a brush that is not too stiff, and, providing the operator takes his time and uses a good mixture of soft soap and paraffin, it can be got rid of.

THOMAS STEVENSON,
(Head-gardener to E. Mocatta, Esq.)
Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Anemones and Ranunculuses.—Those who did not plant their Anemones of the coronaria type or their double French Ranunculuses in autumn may do so now, provided the weather conditions are suitable. Both delight in a rich, light soil deeply worked. Plant about two inches deep, and see that the crowns are uppermost. If sharp frost occurs, a little light protection should be given.

Chrysanthemums.—There need be no hurry with the propagation of early Chrysanthemums. Still, where the young shoots are pushing early, it is better to take cuttings now. They can be struck in boxes in a greenhouse with a rather close atmosphere. As to varieties, their name is legion; but Lady Mary Hope, Miss Balfour Melville, Lady, Rosie, J. C. Grieve, Massé Improved and Abercorn Beauty are worthy of inclusion in any collection.

Early Sowings.—Several things should be sown now, and, among others, East Lothian Stocks, one of the sheet-anchors of the gardener for a summer and autumn display. White, scarlet, crimson and rose shades are all valuable. Sow in pans or boxes, and cover with panes of glass till germination takes place. If water is required, always supply it by partial immersion. Other seeds to be sown now include Aquilegia, Centaurea candidissima, Pentstemon, Ricinus, Scabiosa and Verbena.

The Rose Garden.

Pruning Climbers.—All classes of Roses now embraced by that convenient word "Rambler" may now be pruned. Considerations of space forbid details, but, speaking broadly, all weakly or badly-ripened main shoots should first be cut away; then one or two of the oldest main stems, and a sufficient number of the best-ripened of last year's growth retained to replace those cut away. All laterals should be cut back to within a few eyes of the main stem. On pergolas and screen fences the only general principle to be observed is that of keeping the framework of the tree reinforced by timely supplies of young, well-ripened wood.

Planting.—Where from any cause the work could not be carried out in November, it should be pushed forward as soon as practicable. On heavy ground it will facilitate the production of young fibrous roots if a good spadeful of old potting soil is worked in among the roots when planting.

The Rock Garden.

Top-Dressing.—If the weather permits, the work of top-dressing may now be carried through with advantage whenever necessary. Different subjects require different soils, and a good plan is to take them in groups, making up a batch of soil that will suit (with modifications) a certain group and disposing of it first, and so on, group by group. Where it can be done without injury to the roots, the surface soil should be stirred a little before applying the top-dressing.

Plants Under Glass.

Repotting Ferns.—Many Ferns only require repotting every two years if the work of top-dressing is attended to. All plants requiring repotting should have attention, however, before growth becomes active, or the young fronds are apt to get damaged in the process. Recent experience has proved that peat is not a necessity for a great many species. This is especially the case with Adiantums and Pterises, both of which luxuriate in loam, Oak or Beech leaf-mould and sand.

Hydrangeas.—Old plants may now be repotted. Reduce the balls and pot them into a size larger than they occupied before. They are gross feeders and require a rich compost.

Pelargoniums of the Regal and fancy type should now receive their final shift, bearing in mind that they should be rather restricted as to root-room. Vaporise occasionally to ward off green fly.

Chrysanthemums.—Japanese varieties that were rooted singly in 2½-inch pots will now be ready for shifting into 3½-inch pots. For this potting a compost of loam, two parts, and good leaf-mould and old Mushroom manure, one part each, with a dash of sharp sand, will be suitable. Stand near the glass, and spray once a day for a week if the weather is bright. Decoratives as they become rooted must be gradually inured to full air and then be potted off into 3½-inch pots, two or three in a pot, according to the habit of the variety or the purpose for which the plants are ultimately intended.

Alpinia Sanderae.—This is a near relative of the Ginger Plant, belonging to the Order Zingiberaceae, and it is certainly one of the most lovely variegated plants in cultivation, as anyone can prove by paying a visit to the Royal Botanic Gardens, Edinburgh. It is planted out in one of the stove-houses there, where it is growing luxuriantly; but I understand it is equally amenable to pot culture. Somewhat Dracaena-like in general appearance, it seems an ideal plant for house decoration.

Sow Now Eucalyptus globulus and E. citriodora, Grevillea robusta, Saintpaulia ionantha, Smilax, Streptocarpus and Torenia Fournieri.

Fruits Under Glass.

Vines which have been bent downwards and have now broken freely should be tied up into position and disbudded. The late house may now be shut up and a night temperature of 45° maintained, with a rise of 5° during the day.

Strawberries.—The main batch should now be brought indoors and accommodated in a late Peach-house if available.

The Kitchen Garden.

Peas.—A sowing should now be made without delay, and Gradus is hard to beat for this sowing.

Leeks require a long period of growth, and they should be sown in rows a foot apart in rich soil on a south border. Where large sorts are aimed at, the Lyon is perhaps the best variety, but for general purposes Musselburgh (if true) is excellent.

Parsley.—A sowing should now be made indoors in a warm greenhouse temperature. As this vegetable is largely used for garnishing, some really good variety, such as Dobbie's Exhibition, should be used.

Carrots and Turnips.—An early sowing should now be made in a frame on a slight hot-bed, as recommended a fortnight ago.

CHARLES COMFORT
Broomfield Gardens, Davidson's Mains, Midlothian.

PLANTS FLOWERING OUT OF SEASON.

SOME INTERESTING RECORDS.

HAVING, since 1893, carefully noted abnormal dates of flowering in the case of certain wild or semi-wild flowers which are characteristic of their respective seasons, Mr. Bowles' article in your issue of the 18th ult. interested me greatly—so much so that I looked up my notes on the subject, and also the available rainfall records for the years antecedent to those noted.

My experience is that wild flowers are not so responsive to mild weather in autumn, winter and early spring as are garden flowers, so that for comparisons of this kind they are more valuable than the latter. Since 1893 the spring flowers have been exceptionally early in 1894, 1903 and 1912, as my records show, and, of course, in the current season, 1912-13. Out of the various flowers available which are generally very regular in their time of opening, I will take two as examples, namely, the common Snowdrop and the wild Sweet Violet. The Snowdrop's average appearance here is during the last few days of January or the first week of February, and wild Violets begin to blossom as a rule about March 21. In the years above mentioned they came into flower as follows: Snowdrop—January 20, 1894; January 27, 1903; January 6, 1912; December 20, 1912. Violet—February 20, 1894; February 17, 1903; February 18, 1912; January 7, 1913. These dates are, of course, those on which the first blossom was found, but the whole season in each case was correspondingly early; for instance, I found Hawthorn in leaf on February 7, 1903, and have already seen the young leaves unfolding this year.

The cause of this occasional precocity is more difficult to ascertain. The really warm winters and early springs since 1893 were 1894, 1896 and 1903. Last year, which was earlier than any of these, was not at all a forcing season from January to April. In 1896, which was the mildest winter I remember, and which followed a very hot and dry summer, the spring flowers, though earlier than usual, were later than in any of the years mentioned, and not far from the normal.

Mr. Bowles attributes this early flowering to spring drought, and, referring to the rainfall figures, we find the totals for the three months—March, April and May—were, in 1893, 1.08 inches (Greenwich); in 1902, 5.10 inches (Greenwich); in 1911, 4.15 inches (Woodbridge Abbey, Suffolk); in 1912, 3.39 inches (Woodbridge Abbey, Suffolk); or taking April alone .12 inch (Greenwich); .41 inch (Greenwich); 1.20 inches (Woodbridge Abbey, Suffolk); and .19 inch (Woodbridge Abbey, Suffolk), all being below the average, and three of them very much below. All the autumns (September, October and November) were mild, but neither very warm nor very wet. The summers of 1893 and 1911 were very dry; in 1902

and 1912 they were wet as a whole, with dry periods; 1893 and 1911 were abnormally sunny during June, July and August; 1902 was about normal, and 1912 hardly saw a day's bright sunshine.

In order of early flowering the years were: (1) 1913, (2) 1912, (3) 1894, (4) 1903. The years 1894 and 1903 varied in order of precedence with different flowers; whereas in order of rainfall they were (1) 1893, (2) 1912, (3) 1911, (4) 1902, or, for April only, (1) 1893, (2) 1912, (3) 1902, (4) 1911. April, 1911, had the largest rainfall of the four years, and yet the spring flowers were earlier in 1912 than in either 1894 or 1903, which scarcely accords with Mr. Bowles' theory; and, again, the spring and summer of 1895 were nearly, if not quite, as dry and hot as 1893 and 1911, and yet 1896 does not come into the list at all. If, on the other hand, it is not April, but the general character of the spring which causes this earliness, why should this year be so much earlier than last.

A MODERN METHOD OF SHOWING SWEET PEAS. THIS LARGE AND BEAUTIFUL GROUP WAS STAGED BY MESSRS. SUTTON AND SONS AT WOLVERHAMPTON FLORAL FETE LAST YEAR.

when there was only .75 inch difference in the spring rainfall and six hours' difference in the sunshine records, 1911 having both more rain and more sun than 1912?

I am inclined to think that while there is a great deal in Mr. Bowles' theory, comparing the early years with one another, it looks as if there were some other factor at work as well. Can it be that we are still feeling the effects of the hot summer of 1911, but did not feel the effects of the equally hot summers of 1893 and 1895 respectively two years later because the winters of 1895 and 1897 were too cold? The remarkable similarity of my wild flower records for December, 1894, and December, 1912, supports this suggestion strongly, for it must be remembered that the severe winter of 1895 did not begin till the latter part of January and was most felt during February; or are we experiencing the effects of two dry springs with no intervening hard winter to neutralise them?

Hadleigh, Suffolk.

E. H. DIPNALL

CLASSIFICATION OF SWEET PEAS.

We quote the following from the National Sweet Pea Society's Annual:

"The floral committee of the National Sweet Pea Society presents the following as an up-to-date selection of varieties placed in alphabetical order. * Indicates a grandiflora variety; all others are waved.

Bicolor.—Arthur Unwin, Colleen (A.M., R.H.S., 1909), Mrs. Andrew Ireland (F.C.C., 1908) and Mrs. Cuthbertson (A.M., R.H.S., 1912).

Blue.—Flora Norton Spencer, *Lord Nelson (A.M., 1907) and Mrs. G. Charles.

Blush.—Mrs. Harcastle Sykes (A.M., 1905) and Princess Victoria (A.M., R.H.S., 1907).

Carmine.—John Ingman (F.C.C., 1904).

Cerise.—Cherry Ripe (A.M., 1910) and Decorator (A.M., 1912).

Cream, Buff and Ivory.—Clara Curtis (F.C.C., 1909), Isobel Malcolm and Paradise Ivory (A.M., 1908).

Cream Pink (Pale).—Gladys Burt, Lady Miller (A.M., 1912), Mr. B. Dickson (A.M., 1910) and Mrs. Rontzahn.

Cream Pink (Deep).—Constance Oliver (A.M., 1908), Doris Usher (A.M., R.H.S., 1909) and Mrs. R. Hallam.

Crimson.—King Edward Spencer, Maud Holmes and Sunproof Crimson (A.M., 1909).

Fancy.—Afterglow, Charles Foster (A.M., 1909) and Prince George.

Lavender.—Florence Nightingale, Lavender George Herbert (Dobbie's), Masterpiece (A.M., 1910), R. F. Felton (A.M., 1912) and True Lavender.

Lilac.—Agricola (A.M., 1912).

Magenta.—Merie Christie.

Marbled and Watered.—Helen Pierce (F.C.C., 1907) and May Campbell (A.M., 1911).

Maroon.—Black Knight Spencer, Subian and Tom Bolton (A.M., 1906).

Maroon Purple.—Arthur Green (A.M., 1910) and Mrs. J. M. Gerhold.

Maroon Red.—Brunette (A.M., R.H.S., 1912) and Red Chief.

Mauve (Dark).—Hebe-Paradise, Queen of Norway (A.M., 1906), Fernant Spencer and Wenwe Castle.

Mauve (Pale).—Improved Bertrand Deal (A.M., 1912), Mauve Queen (A.M., 1911), Mrs. R. H. Carrad and Wimsome.

Orange Pink.—Edrom Beauty (A.M., 1909), Helen Grosvenor and Helen Lewis (F.C.C. and S.M., 1905).

Orange Scarlet.—Dazzler (A.M., 1909), Edna Unwin (A.M., R.H.S., 1909) and Thomas Stevenson (F.C.C., 1911).

Prater Edol (Cream Ground).—Evelyn Hemus (A.M., R.H.S., 1907) and Mrs. C. W. Breslmore.

Picolée Edged (White Ground).—Elsie Herbert (A.M. 1906), Marchioness of Tweeddale and Mrs. Townsend. Pink (Deep).—Countess Spencer (F.C.C., 1901) and Hercules. Pink (Pale).—Elfrida Pearson (A.M., R.H.S., 1910). Rose.—Marie Corelli, Marjorie Willis and Rosabelle. Salmon Shades.—Barbara (F.C.C., 1911), Earl Spencer (A.M., R.H.S., 1910), Melba (A.M., R.H.S., 1912) and Stirling Stent (F.C.C. and S.M., 1910). Scarlet.—George Stark (F.C.C. and S.M., 1908), Red Star (A.M., 1911) and Scarlet Emperor. Striped and Flaked (Purple and Blue).—Loyalty and Sufragette. Striped and Flaked (Chocolate and Grey Ground).—Senator Spencer and W. R. Beaver. Striped and Flaked (Red and Rose).—America Spencer, Aurora Spencer and Mrs. W. J. Unwin (A.M., 1909). White.—Dorothy Eckford (F.C.C., 1902), Etta Dyke (A.M., 1906) and Nora Unwin (A.M., 1907).

THE BEST SWEET PEAS.

One of the most interesting features of the National Sweet Pea Society's Annual this year is the numerous answers to questions that were sent out to members at the commencement of the Sweet Pea season last year. Among these, members were asked to name the best six varieties of Sweet Peas for garden decoration, the best twelve Sweet Peas in cultivation, the best three novelties of 1911-12, and the six strongest-growing Sweet Peas. An analysis of the replies was compiled by Mr. J. Harrison Dick and published in the Annual, and we quote this below.

The following selections show, as the result of an analysis of "Expressions of Opinion," what the members generally consider the best varieties:

SIX BEST VARIETIES FOR GARDEN DECORATION

(Analysis of Answers to Question 1.)

Table with 3 columns: Rank, Name, and Votes. 1. Maud Holmes (33 votes), 2. Etta Dyke (24), 3. Mrs. Hugh Dickson (21), 4. Thomas Stevenson (18), 5. Elfrida Pearson and Mrs. W. J. Unwin (16), 6. Nellie Jenkins (15).

TWELVE BEST SWEET PEAS IN CULTIVATION

(Analysis of Answers to Question 2.)

Table with 3 columns: Rank, Name, and Votes. 1. Thomas Stevenson (53 votes), 2. Clara Curtis (42), 3. Elfrida Pearson and Maud Holmes (40), 4. R. F. Felton (39), 5. Elsie Herbert (37), 6. Nubian (36), 7. Mrs. C. W. Broadmore (35), 8. Etta Dyke (33), 9. Hercules (30), 10. Mrs. Hugh Dickson and Sunproof Crimson (23), 11. Barbara, Edrom Beauty, John Ingham, Melba and Mrs. Cuthbertson (21), 12. Charles Foster and Mrs. W. J. Unwin (20).

BEST THREE NOVELTIES OF 1911-12.

(Analysis of Answers to Question 3.)

Table with 3 columns: Rank, Name, and Votes. 1. R. F. Felton (36 votes), 2. Mrs. W. Cuthbertson (18), 3. Edith Taylor (15).

Other varieties finding favour were, Melba, 14; Barbara, 13; Scarlet Emperor, 11; Red Star, 8; Thomas Stevenson, 7; W. P. Wright, 7; Afterglow, 6; and Hercules, 6.

SIX STRONGEST-GROWING SWEET PEAS.

(Analysis of Answers to Question 4.)

Table with 3 columns: Rank, Name, and Votes. 1. Mrs. C. W. Broadmore (38 votes), 2. Elsie Herbert (34), 3. R. F. Felton (27), 4. Hercules and Maud Holmes (22), 5. Mrs. W. Cuthbertson (20), 6. John Ingham and Sunproof Crimson (16).

THE EDITOR'S TABLE.

Cotoneaster angustifolia.—Mr. J. Comber, Nymans Gardens, Handcross, Sussex, sends fruiting sprays of this interesting shrub with the following note: "Some fine sprays of this Chinese shrub were exhibited by Mr. G. Pail on behalf of the grower, M. Vilhorn, at a meeting of the Royal Horticultural Society on November 26, 1904, when it received a first-class certificate. Subsequently a coloured plate appeared in THE GARDEN. Many besides ourselves must have been induced to try it, and it is probable that there are now numerous fine specimens in this country; but, as far as I am aware, very few have been recorded.

A specimen planted in 1905 has for the past two seasons fruited abundantly in these gardens. At first it grew rapidly, soon reaching the height of 6 feet, afterwards making horizontal shoots 2 feet or 3 feet in length each season. The points rarely matured, and were more or less injured by frost. Transplanted to poorer ground and an open, sunny position, it has since reached the width of 12 feet; but the growth is sturdy and has borne an increasing quantity of fruit. The berries are the size of small culinary Peas, and cast their downy covering in October, gradually passing from greenish yellow to brilliant orange yellow. Their abundance gives the plant a most ornamental appearance. Unfortunately, as far as my experience goes, they are not very persistent, for having lasted in full beauty only six weeks, they now (January 22) fall readily at the slightest touch. No pruning is needed, the plant as it ages forming a handsome bush."

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

DOUBTFUL PLANT (Enquirer). In all probability you are enquiring for Senecio elegans, which may be obtained from any good seed-house in crimson, purple, rose, white and other shades. All are easily raised from seeds, the varieties ranging from 9 inches to 18 inches high.

ADONIS FROM SEED (E. T. W.).—All the Adonises should be sown soon after maturing, preferably in slight warmth, i.e., 45° or 50°. A light, sandy, well-drained soil is best, and a soil covering about twice the depth of the seed. Where the seed is long kept out of the soil, it is apt to remain two seasons before vegetating. We do not know the species referred to, and would be interested to learn more concerning it.

ANNUALS FOR SHADY BORDER (Regular Reader).—Most annuals prefer sun, though many are quite indifferent. One of the most important, of course, is the Sweet Pea, particularly the scarlet shades, which not infrequently "burn" when grown fully exposed. For several years we have grown a collection within the shade of fruit trees. Others of service are Asters in variety, Cornflower, Calliopsis, Candytuft, Sweet Sultan, Statice sinuata and the Wallflowers Antirrhinums and Canterbury Bell—among biennials are worthy of note and, if well grown, are capable of a good display.

JUDGING SWEET PEAS (P. C.).—As you have had no experience in judging Sweet Peas and do not know the points which go to make a good spike, the best thing for you to do is to leave the task to someone better qualified to undertake it. It is unfair to you to be called upon for so technical a duty, and unfair to the exhibitors that their blooms should be adjudicated upon by one who is not fully qualified. If you write to Mr. Charles H. Curtis, 2, Adelaide Road, Brentford, Middlesex, he will gladly send you the rules of the National Sweet Pea Society, and for 2s. would send you a copy of the "Sweet Pea Annual," containing the report of a conference on judging; but you must specify that it is this particular one that you want. No. 2 competitor may not enter.

PRIMULA FROM AROLLA (R. S.).—If the Primula is really P. farinosa, it would now be more or less in the crown-bud stage. The plant in flower is 4 inches to 6 inches high, the rosy lilac flowers borne at the summit of a frail stem covered by a dense whitish meal or farina. The leaves are also similarly characterised. The plant is plentiful in the upland pastures of the Alps. The first week of May would be early to flower it, unless frame culture be resorted to throughout, and even then a little artificial

help may be necessary. Such treatment, however, robs these things of their grace and charm, and not a little, too, of the colour. In the larger pot the plant should flower well. It is by no means difficult to grow, and is best perpetuated by means of seeds sown as soon as ripe.

GENTIANAS (A. de G.).—The main essentials for the successful culture of Gentiana acaulis are a sunny position, good loamy soil with a fair proportion of gritty sand and a reasonable amount of moisture. If it is intended to divide the plants, the best time to do so is directly the flowers are over; but when established clumps are obtainable, they may be planted during the autumn and winter months whenever the weather is suitable. They should be planted firmly, and it is very essential that they are at no time allowed to suffer for the want of moisture. The hardy Cyclamen may be planted to early autumn when dormant or nearly so.

DRAINAGE FOR ROCKERY (H. J. C.).—Either the clinkers or the chalk would do quite well—anything, indeed, that will permit of a free passage of superfluous moisture. You might, in your case, have 9 inches of it before you start building, though this amount might require modification, according to circumstances. For example, you say nothing of its position, high or low, whether on sloping bank, nearly level ground, or in a depression. If the rockery is of any extent, a little expert advice on the spot would be money well spent, and probably save you much future disappointment and many failures. Sandstone will do quite well of the right kind. Some sandstones, however, are of little value. Grit and leaf-mould and the addition of burnt ballast would be much better for mixing with the soil than chalk from the gasworks, which may to some extent be impregnated by the gas itself. A heavy soil is certainly not the best for the cultivation of choice alpinists, though you do not say what you contemplate cultivating.

PLANTS FOR STREAMSIDE BORDER (Asphodel).—For this particular purpose the Tunica, Sedum, Androsaces and Geranium would be quite unsuitable; the Callitha, much too early in flower. The Eriogonum is also a trailing subject far better suited to the rock garden or rockery border, where it might trail among stones. Indeed, the only really suitable things your list contains are the Lobelias and Japanese Irises. To these latter you might add I. aurea, I. Monnierii and I. pallida dalmatica. Other good things would be some of the newer Astilbes, as Ceres, Peach Blossom and Queen Alexandra, Spiraea Filipendula fl.-pl., Lobelia cardinalis, L. Queen Victoria, Lilium canadense (in peat), Primula japonica, P. pulverulenta (a notable plant indeed), Anemone japonica in red, pink and white shades, and Senecio Doronicum. To make a show, the whole of these should be planted in groups, say, three or half-a-dozen plants to each group. As you say nothing of the extent of the border, we cannot suggest in this direction at all. The easiest rock plants to raise from seeds are Aubrietia, Alyssum, Saxifrage (Mossy sorts), Tunica Saxifrage, Silene alpestris, Achillea (any), Acantholimon glumacum, Campanula in variety, Sedums, Saponaria ocyroides, Armeria, Eriogonum of sorts, Iberis, Coronilla, Hutchinsia alpina and Dianthus in variety.

ARUM LILIES FOR STREAMSIDE GARDEN (L. B.).—Calla elliptica differs so markedly from the ordinary Arum that you are not at all likely to succeed with it under the conditions named. In the first place, the ordinary kind (Calla or Richardia aethiopica) is a native of Cape Colony, where it frequents ditches and similar spots, and in some places there frosts are not unknown. C. elliptica, on the other hand, comes from a warmer district further North; hence it would not survive an English winter. There yet remains another and very important item, and that is the ordinary Arum is practically an evergreen unless it is dried off during the summer, whereas elliptica behaves quite differently. This last named forms a flattened tuber, much resembling that of a Caladium, and, like it, passes the winter in a totally dormant state, during which period it should be kept quite dry. Shaken quite clear of the old soil and repotted in February in a mixture of loam, leaf-mould, well-decayed manure and sand, it will, in a temperature of 55° to 65°, start freely into growth and push up its handsome, spotted leaves, soon after which the flowers make their appearance. When the pots get full of roots, an occasional stimulant will be helpful. After flowering, the plant must be kept in the greenhouse for another season, and the formation of flowers for another season. By the end of the summer the plant will show signs of going to rest by the leaves turning yellow. When this happens, the water supply must be lessened, and, when quite dormant, discontinued altogether.

TREES AND SHRUBS.

CLIMBERS FOR HURDLES (A. C.).—A mixture of green-leaved Ivy and Jasminum nudiflorum would look very well in the position you describe, or, if the position is not exposed to great cold in winter or early spring, Escallonia launceolata might be used. The latter plant forms long, graceful shoots, and bears large quantities of rosy red flowers during the summer. It will stand 15° or 18° of frost without harm, providing the frosty period is not a prolonged one; but when over 20° are experienced it is liable to injury. The Ivy and Jasmin combination forms, of course, a pretty winter effect, for the flowers are at their best during January. The greenery of the Ivy, however, remains the year round, and a summer-flowering Clematis might be placed with it, for that could be cut down in winter.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Sweet Pea Edith Taylor.—On page 52 of our last issue we inadvertently stated that this Sweet Pea was sent out by Mr. Robert Holmes. Although raised by him, it was sent out by Robert Sydenham, Limited, Tenby Street, Birmingham.

Two Uncommon Ornamental Trees.—Planters of ornamental trees are sometimes at a loss to know what to secure in the way of uncommon subjects. Two distinct trees for planting in gardens are *Cedrus atlantica pendula* and *Pinus sylvestris aurea*, the former a weeping form of the well-known *Cedrus atlantica*, the latter a beautiful golden form of *Pinus sylvestris*. Both are splendid for isolated specimens in the pleasure grounds.

The Victoria Medal of Honour in Horticulture.—To fill the three vacancies caused by deaths during the past year, the Council of the Royal Horticultural Society have bestowed the Victoria Medal of Honour in Horticulture on Mr. Divers, the well-known head-gardener at Belvoir Castle; Mr. Whytton, Superintendent of Glasgow City Parks; and the Rev. W. Wilks, for twenty-five years the esteemed secretary of the society.

A Primula Conference.—On April 16 a Primula Conference will be held by the Royal Horticultural Society at Vincent Square, when Sir John Llewelyn, Bart., will occupy the chair. The papers to be read are as follow: "Himalayan Primulas," by Mr. Craib of Kew; "European Hybrids in Nature," by Mr. Reginald Farrer; "Primulas from a Garden Point of View," by Miss Jekyll; "Chinese Species of Primula," by Professor Bayley Balfour, F.R.S.; and "European Primulas," by Dr. John McWatt.

Dwarf Shrubs for the Rock Garden.—Among dwarf shrubs for planting on narrow borders or on the rock garden, the following are very interesting, and are not seen so often as their merits deserve; *Berberis buxifolia*, *Olaria nummulariæfolia*, *Genista sagittalis*, *Veronica cupressoides*, and *V. pinguifolia*, the latter having grey foliage. These subjects are of easy cultivation, and do not require constant pruning to keep them in shape. Many so-called dwarf shrubs are only kept in bounds by constant pruning, and however neatly this operation is performed, it is often advisable to use plants which do not require the constant use of knife or shears.

Ornamental Crab Apples for the Conservatory.—Among the numerous hardy trees and shrubs which are forced for conservatory decoration, the best of the Crab Apples are great favourites, both on account of their free-flowering qualities and delicate colouring. A group composed principally of *Pyrus floribunda*, its variety *atrosanguinea*, and the semi-double-flowered *P. Scheideckeri* was noted on January 25 in the greenhouse at Kew,

where it was certainly one of the damtiest and most admired features. The plants of *P. floribunda* were 10 feet or 12 feet high and well flowered throughout, *P. Scheideckeri* being bushes 3 feet or 4 feet in height. The elegance of such plants and the pretty shades of the flowers open up a wide field of possibilities for the exercise of the decorator's art, for in conjunction with white-flowered or foliage plants many effective arrangements might be made.

A Useful Annual for the Greenhouse.—Among the various annuals that, sown in pots in the spring, are of considerable value for the embellishment of the greenhouse later on must be included *Rhodanthe Manglesii* and its white-flowered variety. The seed sown now will quickly germinate, and, providing it is grown in a good light, any position in the greenhouse, so that the young plants do not become drawn, it gives but little trouble. By some the seeds are sown in the pots in which they are to flower, while by others they are sown in pans or boxes and pricked off therefrom into their flowering pots, which are, as a rule, 5 inches in diameter. From eight to ten plants are put in a pot.

Apples with Many or No Pips.—At a recent meeting of the scientific committee of the Royal Horticultural Society, Mr. Chittenden showed specimens, to which reference has already been made, of Apples having more than two seeds in the capillary cells. The variety *Duchess's Favourite* had, as a rule, in the past season four seeds in each cell, and in one case five had been found. This is remarkable, as the number in the wild types is practically constantly two, and that has been used as a basis of separation between the genera *Pyrus* and *Cydonia*. He also showed specimens of an Apple called *No-Pip*, which was reputed to form no seeds, although the Apple was perfectly developed. Those exhibited had only the merest rudiments of seeds, apparently no larger than the ovules had been.

Camellia reticulata.—To many people the irregular-shaped flowers of this species appear more beautiful than the flowers of the varieties of *C. japonica* with their formal outline, and everyone who sees a bush in full bloom is impressed by its beauty. A native of Hong Kong and China, it forms a large bush, with longer and more slender shoots than *C. japonica*. The flowers resemble those of a semi-double *Pæony*, for the red petals are of irregular size and shape, and enclose a central mass of yellow stamens, a single flower being from 5 inches to 6 inches across. Unfortunately, it is less hardy than *C. japonica*, and may not be grown out of doors, even in the milder counties, unless it is given the protection of a wall. It is, however, an excellent plant for planting in a border in a greenhouse or conservatory, where it may be trained against a wall or allowed to assume bush form. Under glass it blooms during January and February.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

The Herbaceous Border at Hopetoun House, Linlithgowshire.—In my notes in THE GARDEN of January 11, page 22, I regret having omitted to give the dimensions of the fine herbaceous border at Hopetoun House, an illustration of which was given. The total length is 167 yards and the width 18 feet.—C. BLAIR.

Rose Herzogin Marie Antoinette.—I was much interested in Mr. Herbert E. Molyneux's note on the above Rose on page 45 of THE GARDEN for January 25, and was glad to observe that he had grown it. Many Continental varieties of great merit are apt to be overlooked, and the Rose under notice is a case in point. It is certainly a good decorative Rose.—GEORGE M. TAYLOR, *Mullothuau*.

Fatsia japonica Hardy in Lancashire.—In reference to the note about this plant on page 30, issue January 18, it may interest readers to know that it is quite hardy here. There is a plant of it here that has been outdoors for eight years, and it is a fine one, with leaves down to the ground. It is 5 feet 6 inches high and as much through. It has had no protection whatever.—H. GLOVER, *Onell, near Wigan*.

Plants Flowering Early.—I have read with interest your various correspondents' notes on the early flowering of various plants. In these gardens on January 8 there were fifty-three different species of plants in bloom outside, the most remarkable being *Olearia Gunnii*, which had ten flowers open and numerous on the point of bursting, and *Staphylea colchica*, with four sprays of blossom fully open; while *Anemone alpina*, *A. blanda* and *Cyclamen Coum* are patches of bright colour.—A. GRANT, *The Gardens, New Place, Haslemere*.

Flowers in British Columbia.—So many people are now interested in Canada, but I think the climate in places is misunderstood. For instance, here in my garden in Victoria, B.C., I had the following plants in bloom on January 3: *Roses*, *Chrysanthemums*, *Auriculas*, *Violets*, *Geraniums*, *Snowdrops*, *Hypericums*, *Calceolarias*, *Helleborus*, *Aubrietias*, *Pansies*, *Primroses*, *Wallflowers*, *Stocks*, *Fuchsias*, *Dianthus*, *Antirrhinums*, *Cineraria stellata*, *Daisies*, *Lupines*, *Primulas*, *Eschscholtzias*, *Hollyhocks*, *Portulaca*, *Poppies*, *Mignonette* and *Arabis*.—T. B. PEMBERTON.

The Hardiness of Campanula isophylla.—At the conclusion of a lecture which I gave the other day, an interesting discussion took place on the question of the hardiness of *Campanula isophylla*. In my lecture I stated that I had been unable to keep it in the open in the neighbourhood of Dumfries; that I had never seen it standing in the open in this part of the country; and that the finest plants of *C. isophylla* I had ever seen in the open were in Ireland. Several who were present practically confirmed what I had said regarding this Bell-flower in this part of Scotland, but one gentleman stated that when in Lancashire he had seen *C. isophylla* standing through the winter in pots in the open, and subjected to treatment which many professing hardier flowers would not stand. In view of these remarks it would, I think, be an advantage if others who have tried *C. isophylla* out of doors would give us the benefit of their experience. I may add that the plants in Ireland to which I referred were grown

on a sheltered wall in Dublin and were exceedingly fine. Nowhere do we see this plant better grown than in cottage windows, and many fine examples are to be met with in this district.—S. ARNOTT, *Dumfries*.

Old Cyclamen Plants.—In THE GARDEN for January 18 you ask readers for particulars concerning the age of Cyclamen. I have a friend who has some plants twenty years old, and which flower profusely each year. I have seen them yearly for the last six years, so I can vouch for their flowering well. Speaking to him last week on the topic, he informs me that they can be kept as remarked in your note. He also believes in keeping them when he has good colours, as he knows what he is growing.—GEORGE CRABBE, *Woodside*.

Sowing Early Peas.—I quite agree with the method of sowing seeds of early Peas as practised by the late Mr. Charles Foster and referred to in "Notes of the Week," issue January 18. For several years, having ample space in a six-acre kitchen garden, I sowed some seeds of early varieties of Peas in December and January and chanced what the result would be. Having plenty of dry soil from the potting-shed and root stores, I covered the seed 1 inch deep with it in a dust dry state, and then put on a thin layer of the border soil. The border was a warm one on the south side of a 12-foot-high fruit wall, and we had no failures except once, when rats did a lot of damage. The pods were ready to gather about a week earlier than those grown on plants from later sowings.—AVON.

The Newer Roses.—On page 21, date January 11, is a suggestion by Mr. H. E. Molyneux that readers should send a list of the newer varieties they have tried and proved satisfactory. Among others, we have tried the following, which have, on the whole, in growing and flowering given every satisfaction: Miss C. Forde, Lady A. Stanley, Mrs. C. Miller, Lady Pirrie, Jonkheer J. L. Mock, Mrs. A. Munt, My Maryland, Entente Cordiale, Mrs. E. G. Holland, E. Mawley, Herzogin Marie Antoinette and Rosomane Thomas (catalogued as a Tea variety). To particularise, I may add that Mrs. Holland, E. Mawley and Herzogin Marie Antoinette do not appear any too strong in making growth, but perhaps time may set this matter right, while the last of the three is very free-flowering. I think this list only dates back to 1909. Our soil inclines to stiffness, and the plants get liberal attention.—C. T., *Hughgate*.

Roses Grown Near London.—A few words regarding a Rose which I have seldom seen mentioned in your columns, but which I have found a very suitable one for town gardens, may be of interest. I refer to Mme. Hector Leuilliot. While it is quite true that it is not one of those Roses which are remarkable for their freedom in producing flowers, still, I think it is well worthy of being more generally grown, it being very hardy, a good strong grower, with lovely foliage, and one that appears to thrive on a poor soil. The colour of its blooms is extremely rich orange, the outer petals being somewhat paler and prettily veined; they have, moreover, a pleasant, fruity fragrance. In a cool summer similar to what we experienced last year, the blooms are even deeper and richer in colour. The blooms are full and hang their heads slightly, but I do not consider that this detracts anything from their loveliness when the plant is grown at the foot of trellis-work and the growths trained and tied back to hide the same. A tree

of this variety that I have growing in this manner made splendid growth even for the remarkable summer we experienced last year. One shoot I measured was fully 14½ feet long, while some of the leaves on it were 10½ inches in length. This vigorous growth appears wonderful to me when taking into consideration the light, stony soil in which it is planted and how confined the gardens are in the immediate vicinity where I reside. Perhaps some others of your readers would give their experiences with this variety.—H. A. FORDHAM, *Forest Gate, E.*

Ranunculus Lyalli in New Zealand.—As the writer of a note on this subject which appeared in THE GARDEN about two years ago, I was, naturally, greatly interested in Mr. Willcox's note and the charming illustration of a portion of his rockery which appeared in your issue for January 18, page 34, with *R. Lyalli* (one of the finest of all sub-alpines) nestling in the background. In my note I advocated its extended culture in this country, but was informed by your esteemed correspondent Mr. S. Arnott that the plant is difficult to establish, and that attempts had been made which mostly proved a failure. However, I was determined to try, and had two plants sent me by my sister from Invercargill, New Zealand. They, however, proved a failure; the long journey had extracted their vitality to such an extent that after a brave struggle to live they gradually dwindled away. Still, I firmly believe that if we raised our plants from seeds, success would be more assured, and if we follow Mr. Willcox's cultural directions we might establish this new plant in our own country.—J. E. DAVIES, *The Gardens, Talygarn, South Wales*.

Serious Losses Among Roses in Linlithgowshire.—Not for many years have our Roses suffered so severely as they have done during the present winter. Chambers on walls, arches and pillars, in particular, are a sorry sight, while dwarfs have by no means escaped. In this garden our Rose arches are of painted iron, and at first I was inclined to blame these for the losses, but on examining a row of wooden pillars connected by hempen ropes, I find the destruction quite as heavy, while also in other gardens in the district, where all arches, pergolas and pillars are of rustic woodwork, the same serious state of affairs is in evidence. Now, the winter, on the whole, has been anything but severe, so far as frost is concerned, but, owing doubtless to the cold, wet summer, growth was made so late that the wood was very imperfectly ripened, and what frosts we had found everything green and full of sap. The most severe frosts were from November 27 till December 3, and it was this spell of cold weather that did the mischief. So far as my observation serves, the only climbing Rose that has totally escaped is our old friend *Gloire de Dijon*. All our plants of this are on walls, so that they have all the shelter going, but as *Crimson Rambler*, *Grüss an Teplitz* and others have suffered more or less severely when trained in similar positions, it seems evident that the good old *Gloire* is the hardest of all climbing Roses. A good big plant of *Hawatha* on an arch is quite killed, as is also a weeping standard of *White Dorothy*. As I have already said, the dwarfs have not entirely escaped, but it is just too early to determine how serious the loss is among these. Perhaps readers in other parts of the United Kingdom will briefly state their experiences in regard to this matter.—C. BLAIR, *Preston House Gardens, Linlithgow*.

Laurustinus lucidum.—In the various paragraphs that appear from time to time regarding the *Laurustinus*, I am surprised that no one refers to the variety *lucidum*. This has a large, polished, dark green leaf, not corrugated like the type, and the flowers are at least twice the size of the common kind. It is fairly common in Cornish gardens, but is quite hardy. It is not easy to obtain from nurserymen, who sometimes supply the French variety (much inferior) in place of it. It can be obtained in Ireland. I should like to know when it was introduced and from where.—J. A. D., *Noctorum*.

Clematis indivisa in New Zealand.—I am sorry that I am not near enough to send you some flowers for your table, but please accept a photograph of a plant of *Clematis indivisa*, which was planted two years ago in my garden. It covers the top of a rustic fence for a distance of 16 feet. Unfortunately, the camera could not include the whole length. Viewed from the other side, the mass of flowers looked even finer than this, but the background was poor. The plant began to flower on July 29, and there were still a few flowers to be seen at the beginning of November.—FRANK MASON, *Whakaronga, New Zealand*.

SOLUTION AND NOTES OF ACROSTIC No. 7.

"HEATH"—"ERICA."

- *1. H , ELLEBOR E
- 2. E SPALL R
- 3. A MPELOPSIS VEITCHI I
- 4. T SOPMO C (compost)
- †5. H ENN A

H. Andrews published a monograph of the genus *Erica* between 1894 and 1814. Loddiges and Son were celebrated nurserymen at Hackney early in the nineteenth century. *Erica* was the name used by Pliny.—See Nicholson's "Dictionary of Gardening."

* Christmas Rose (*H. niger*) and Bear's-foot (*H. foetidus*). † Folkard's "Plant Lore," page 24. Mahomet called it "chief of the flowers of this world and the next." It is now known as *Lawsomia alba*.

SOLVERS OF ACROSTIC No. 6.

CORRECT solutions of Acrostic No. 6 were sent in by the following: "Leander," L. A. Loudon, "Elm, Bampton," "H. A. T.," Mrs. F. Jones, "Nemo," "Ian Dhu," William Bond, "Rustic," "Retrac," "R. F. B.," "Tempus Fugit," "Brarbank" and Miss G. M. Hallows. In our next issue we hope to publish the names of those who have correctly solved Nos. 7 and 8, and also the names of the prize-winners.

FORTHCOMING EVENTS.

- February 10.—United Horticultural Benefit and Provident Society's Meeting.
- February 11.—Royal Horticultural Society's Annual Meeting.
- February 12.—East Anglian Horticultural Club's Meeting.
- February 14.— Finchley Chrysanthemum Society's Annual Meeting. Beckenham Horticultural Society's Meeting and Lecture.

PRIZES FOR THE BEST SCIENCE IN RELATION TO ROCK GARDENS.

To further stimulate the interest that is being taken in rock gardens, the Proprietors of THE GARDEN offer the following prizes for three photographs of a rock garden, or portions of a rock garden:

- First prize: Five Guineas, or a Silver Cup of that value.
- Second prize: Two Guineas, or Books of that value.
- Third prize: One Guinea.

The competition is open only to the actual owner of the rock garden, or to his or her gardener

HYBRIDISATION.

THE art of hybridisation has gained enormously by the far-reaching discoveries of Mendel. It is no longer a game of chance between the experimenter and Nature. Mendel's carefully-planned researches drew from Nature a knowledge of the controlling laws under which sexual reproduction worked, and of the new forms of life she called into being. No hybridiser nowadays need experiment at

CLEMATIS INDIVISA IN A READER'S GARDEN IN NEW ZEALAND.

The competition is subject to the following rules:

1. Not more than three photographs of each garden may be sent in by one competitor.
2. Each photograph must have the full name and address of the competitor plainly written on the back in ink.
3. Successful competitors shall furnish written particulars of the rock garden forming the subject of their photographs.
4. Glazed and mounted P O P. prints must be sent.
5. All photographs must be sent to arrive at THE GARDEN Offices, 29, Tavistock Street, Strand, W.C., not later than June 1, 1913.
6. Unsuccessful photographs sent in for competition will be returned if a sufficiently stamped and addressed envelope or wrapper is enclosed for the purpose, but no responsibility will be taken for the loss or damage of photographs submitted, although every care will be taken to return them uninjured.
7. The Proprietors of THE GARDEN reserve to themselves the right to reproduce any photograph sent in for competition.
8. The decision of the Editor will be final.

random. His work can be carried along definite and well-defined lines, and, having discovered by experiment certain factors, he is able to foretell the likely results of mating this parent with that. Mendelism, therefore, has given a great impetus to the practice of hybridisation, and has largely contributed to the enrichment of our gardens with improved strains of cultivated plants. A good illustration of the application of Mendel's law, as it is conveniently called, to practical gardening is furnished by a series of interesting experiments on Tomatoes recently carried out at the New York Agricultural Experimental Station by K. Wellington.

Mendel's Laws.—To understand the meaning of the results obtained in these experiments it will be necessary, first, to explain—to those who are not familiar with the working of Mendelian factors—one or two of the first principles underlying the science of hybridisation. The factor determining any given character of a plant, such as height, is inherited; that is, it is transmitted from the seed parent to the offspring or seedling. Pure-blooded "talls" when mated will always produce talls, as the pollen as well as the ova carry the same kind of factor. But what will happen if the pollen

or ova of one parent carries the factor of tallness, and the pollen or ova of the other parent carries the factor of shortness from a pure strain of dwarfs? While the offspring will obviously inherit the power to produce both characters, it is also obvious that it cannot be both tall and short at the same time. It must be one or the other, unless, indeed, it makes, as it were, a compromise and becomes neither the one nor the other, but simply grows to a medium height. But it may not take this latter course, in which case one of the characters will be "dominant"; that is, it will master the other, or "recessive," as it is called. Tallness in Sweet Peas, for example, is dominant to shortness. It follows from this that when a dwarf and a tall Sweet Pea are mated, the progeny of the cross in the first generation will be all tall and all hybrids, hybrid because, although they are all tall, yet they all contain the factor of dwarfness in subjection. Now the next point to understand is that while an individual plant may be hybrid, the individual pollen and ova produced by that plant can never be hybrid in its nature. As the pollen grains are formed, the Mendelian characters separate in twos and twos equally, so that half the number of pollen grains possess the factor of tallness and half the factor of dwarfness, and the same thing happens with respect to the ova, thus:

Pollen		Ova	
1	T	3	T
2	D	4	D

Now, if you take up a quantity of ripened pollen in a camel-hair brush from either the pollen or seed parent and dust it over the stigmas of the other, what are the chances of combination? If pollen No. 1 fertilises ova No. 3, clearly the offspring will be a pure tall; while if it fertilises ova No. 4, the offspring will just as obviously be a hybrid. On the other hand, if the pollen grain No. 2 carrying the pure dwarf-producing factor

1.—APPLE TOWER OF GLAMIS SHOWING EXTERNAL APPEARANCE WHEN ATTACKED BY BITTER-PIT.

fertilises ova No. 4, the resulting offspring will be of a pure dwarf strain; while if it fertilises ova No. 3, a hybrid will be the result. The second generation, therefore, breaks up into three-fourths tall and one-fourth dwarf. But of the three tall one only is pure, the other two being hybrids. If we are dealing with a hybrid "medium," then the second generation will break up into 50 per cent. mediums, 25 per cent. tall and 25 per cent. dwarfs.

Influence of Crossing on Yield in Tomatoes.—

To return now to the experiments with Tomatoes at the New York Agricultural Experimental Station, Mr. Wellington has found that a crop of hybrid plants of the first generation give a larger yield than either of the parental forms, or of the succeeding generations after the "break." The results suggest and seem to warrant the use of first-generation seed only if the main object be the production of a heavy crop. Of course, it entails all the extra care and trouble that artificial fertilisation means; but Tomato fruits, as a rule, produce a large number of seeds, which, so far, is some compensation against the extra trouble. Tomato seeds retain their vitality, it is said, for from three to seven years; therefore it would only be absolutely necessary for seed-growers to raise every third year a sufficient quantity to cover the needs of a three-year sale. It would appear to be a simple matter for raisers of Tomato seed to select pure strains of comparatively heavy croppers and reserve them for breeding purposes. Those not wanted for purposes of hybridisation could be kept pure by self-fertilisation, with the view of keeping up the stock of hybrid mothers. In this work it must be remembered that violent crosses—that is, using parents too widely different—produce not stronger but weaker offspring. Finally, it is known that a corrugated form is dominant to a smooth form, and that a dark red coloration is dominant to pink, and pink dominant to yellow. Size and shape are both inherited characters, and extremes, when mated, tend to produce medium hybrids. It is also said that earliness is slightly increased by crossing.

Royal College of Science for Ireland, Dublin.

THE FRUIT GARDEN.

BITTER-PIT IN APPLES.

DURING the hot summer and autumn of 1911 there were numerous complaints from various parts of the country of the prevalence of bitter-pit in Apples. This was a rather mysterious disease that caused sunken, brown spots to appear under the skin of many Apples, particularly those with soft flesh, such as Warner's King. Although little had been heard of it in this country up to that time, it had been very prevalent in Australia, which, together with the fact that our summer of 1911 was exceptionally dry and resembled the Australian summers, gave rise to the supposition that drought was the indirect cause of the trouble, which also attacks Pears.

We have just received a voluminous but extremely interesting Report on the subject from Mr. D. McAlpine, Government Vegetable Pathologist to the Department of Agriculture for Victoria, Australia. Mr. McAlpine has been investigating bitter-pit in Apples for some years, and the volume we have before us is his First Progress

Report. In our issue for December 2, 1911, we published an illustration of an Apple Tower of Glamis attacked by this disease, and we reproduce this again, so that those readers not familiar with it may get an idea of the external appearance of a fruit so attacked. Mr. McAlpine has come to the conclusion that bitter-pit arises from some derangement of the vascular system of the Apple; and as the matter is one of importance to fruit-growers in this and other countries, we publish his letter, together with the summary of the Report that he sends us and two illustrations from the very numerous and interesting collection that is to be found in its pages. Mr. McAlpine writes:

"I have much pleasure in forwarding you my First Progress Report on bitter-pit in Apples, and although somewhat voluminous, since it clears the ground for future action, you will be able to get an idea of the principal points from the table of contents and from the summary at page 109. One important point has been already established as the result of experiments, viz., that overseas shipments of clean fruit will be free from bitter-pit

2.—VASCULAR NETWORK OF APPLE WITH BITTER-PIT PATCHES ATTACHED. THE NETWORK IS INTERRUPTED WHERE THE BROWN PATCHES OCCUR.

3.—FIBRO-VASCULAR SYSTEM OF A PEAR, SPREAD OUT TO EXPOSE THE CORE.

on reaching its destination if kept at a constant and sufficiently low temperature, viz., 30° to 32° Fahr. The fruit was cooled down to 35° Fahr. and then kept at the above temperature without fluctuations. The scientific explanation of this fact is that at 1° or 2° Fahr. below the freezing point of water, the respiration of the Apple is suspended, and in this state of suspended animation or dormancy the development of bitter-pit is retarded. It would hardly be expected that anything fresh would be found out in such common objects as the Apple or Pear, and yet I have discovered a beautiful and delicate vascular net immediately beneath the skin, which has an important bearing on the origin of bitter-pit, and the purpose of which is to regulate and equalise the distribution of food material in the area where the greatest and most rapid growth necessarily takes place." (See illustration on page 68.)

The summary in the Report referred to is as follows:

"It is a fundamental principle of pathology that the normal structure and functions of the part or organ concerned should be determined as far as possible, in order that the abnormal conditions may be properly understood.

The structure and functions of the Apple and Pear were therefore investigated, with the result that, on the removal of the skin and flesh after softening, there remained a delicate skeleton and vessels as a model of the whole, ramifying through and permeating every portion of the fruit, supplying the seed vessels and the flesh with liquid nourishment, and forming a network of vessels immediately beneath the skin. This vascular network was found to originate in the earliest stages of the fruit, and continues to expand with the enlarging flesh.

It is shown that neither insects nor fungi, bacteria, nor external agencies, such as spraying, are concerned in the production of bitter-pit. Bitter-pit is seen to be an internal disease, due to internal causes, and always found associated with the discoloured vascular bundles. 'Crinkle,' or 'pig face,' or 'hollow Apple' is shown to be a confluent form of bitter-pit, every gradation being observed from pit to slight and advanced crinkle. Large cavities are formed by the rupture of the tissue, owing to rapid and excessive growth at the periphery. Diseases found associated with bitter-pit were 'black spot,' 'bitter rot,' 'glassiness' or 'water core,' and 'mouldy core.'

Appearances mistaken for bitter-pit were hail-marks, bruised skin, effects produced by chemical reagents and local poisoning. Pitted Apples are produced on unsprayed trees, and a chemical analysis of such Apples revealed no trace of mineral poisons.

It was found, as far as my investigations go, that the key to the solution of the bitter-pit problem lay in the wonderful vascular system which permeates the 'core' and the 'flesh,' and the marvellous network of vessels just beneath the skin, their function being to regulate and equalise the distribution of food material at the periphery of the fruit, where the greatest and most rapid growth normally takes place.

The brown spots of bitter-pit are generally first formed in the zone occupied by the vascular net, of which there is not only ocular demonstration in the position of the tough brown spots still adhering to the Apple in which the network is shown (Fig. 2), but in the figure of the Apple reproduced direct from the object itself. There is also a striking confirmation of this in the fact that the same place of origin of the brown spot

has been noted by competent observers in Europe, America and Africa, even although the existence of the network was unknown to them. The earliest external appearance of bitter-pit was noticed when the fruit was about the size of a Walnut, but it generally occurs when the fruit is about half grown or approaching maturity. It generally occurs in the upper half of the fruit and towards the 'eye' end, and this is correlated with the openings in the skin being much more numerous in the upper than in the under portions. Chemical analysis shows that there is less water in the flesh of the upper portion. The larger number of openings will necessarily allow more active transpiration to go on at the 'eye' end than at the stalk end, and, owing to this extra transpiration, there is less water in the flesh at the top.

Bitter-pit may be associated with wet or dry seasons, so long as they are intermittent and fluctuating in their character at the critical period

tree and the fruit formed may be controlled to a large extent by cultivation, manuring, including green manuring, irrigation, the stocks used and the method of pruning. The relation of each of these factors to the development of bitter-pit is being determined by means of experiments. Young and vigorous trees making rapid growth may have pitted fruit, from the rapid transpiration and excessive growth interfering with the regular development of the vascular network. A light crop, with abnormally large fruit, is more liable to pit than a heavy crop of average-sized fruit equally distributed over the tree."

ROCK AND WATER GARDEN.

IRIS VARTANII.

This winter-flowering Iris of the reticulata section is not nearly as widely known or grown as it

A BEAUTIFUL IRIS (I. VARTANII) FOR THE ALPINE HOUSE.

of growth. The principal contributing factors to bitter-pit are:

- (1) Intermittent weather conditions when the fruit is at a critical period of growth.
- (2) Amount and rapidity of transpiration.
- (3) Sudden checking of the transpiration at night, when the roots are still active owing to the heat of the soil.
- (4) Failure of supplies at the periphery of the fruit, followed by spasmodic and irregular recovery.
- (5) Inequality of growth, so that the vascular network controlling the distribution of nutritive material is not regularly formed.
- (6) Fluctuations of temperature when fruit is in store: and
- (7) Nature of variety.

The weather cannot be controlled (except in so far as a smoke-blanket is allowed to drift over the orchard on frosty nights), but the soil and the

deserves to be. Its flowering season is from October to January, and as an Iris for growing in pans to brighten the alpine-house in the dull winter days it has few equals. When grown outside, it should be given a favoured position under a wall or a sheltered niche in the rock garden, while it is one of those plants showing a decided preference for a light soil. The chief colour of the flowers is a slaty blue, the broad falls being almost white, copiously veined with a lavender hue and having a very pretty yellow crest. The erect standards are slaty blue. This Iris is a native of Palestine, and is named after Dr. Vartan of Nazareth.

A CILICIAN CROCUS.

(CROCUS CILICIVS LILACINUS.)

A PRETTY late-flowering Crocus is that called C. cilicivus, which Maw in his "Monograph" refers to the species C. cancellatus. It is the

A NEW MINIATURE NARCISSUS, *N. MINICYCLA*. (Natural size)

Cilician form of *cancellatus*, and it differs but slightly from the type. There are several varieties of this Cilician *Crocus*, generally of different shades of blue. The one named above is of a pale lilac, and looks very pleasing on rockwork in the late autumn and winter. This *Crocus* seems to open with but a moderate amount of sunshine. S. A.

LITHOSPERMUM GRAMINIFOLIUM.

Some years ago I was ascending the very humble Mount Summano up to Solho, near Vicenza in High Italy. The ground was then covered with rare Orchids. It was just the best time for them (June), and I gathered there many charming species in the world of *Serapias*, *Ophrys* and *Orchis*. Suddenly before my eyes arose the most exquisite sight I ever saw. Like in a dream, in a heavenly dream, I saw a blue picture, fringed with pink, formed by a mass of deep azure flowers. "What is this?" I said to the Italian friend who was at my side. "I do not know," he answered, so I hastened and hastened till I was at the slope which was so adorned with the blue, and saw it was the exquisite *Lithospermum graminifolium*, a gem I cultivated for years, but which I had not yet found wild. This made such an impression upon my mind that I shall never forget it. Imagine thousands of millions of such long and thin deep azure flowers, all close to each other, all together pressed on the tuft of grass-like foliage, so dense that no place was free for the foliage. And imagine, still, here

and there, some tufts of that beautiful pink *Linum viscosum* growing together with them, and dark brown *Serapias longipetala* and bright yellow *Coronillas*, all these together under the brilliant sun of Italy. You will have an idea of the charming apparition. And then, in the shady and grassy places, fields of the marvellous cardinal red *Lilium carnulicum*, framed by the deep pink *Epimedium alpinum*, the rocks being covered with *Phyteuma humile* and *P. comosum*, with the deep blue *Paederota* and the delicate *Saxifraga caesia*, every kind of colour and tint, and all in masses in myriads, every rock coloured and adorned, and you will have a little idea of my emotion.

Lithospermum graminifolium is, in my opinion, far better than the Pyrenean *L. prostratum*. The elegance of the flower and the beautiful pure, deep azure of the long, tubular corolla are unsurpassable; but the best of it is that it is the easiest to grow. We have in the wall of *Floraire* two tufts of it measuring 2 feet to 3 feet in diameter, which are indescribable in beauty and vigour. They were singly planted between the stones of the wall in a very sunny place. The plant likes sun, of course, and does not stand well in the misty and damp climates.

Another very good *Lithospermum* is *rosmarinifolium*, from the Abruzzis in South Italy. It flowers in early spring, and again in late autumn, and has deep blue flowers. But it is not quite hardy with us. *L. fruticosum*, from the South of France, is a hardy kind, and forms little bushes of 2 feet to 3 feet, with deep blue flowers. *L. prostratum* is not good here, as we have too much chalk in the ground and in the water. Two creeping sorts of the Pyrenees, *L. olefolium* and *L. Gastonis*, are easy growers, the first having pink and blue flowers and silver whitish leaves, and the other is a low herbaceous kind, with deep, big flowers. The first likes the rockery and a sunny place between the stones; the second, a peaty soil, half shady.

FLOWER GARDEN.

A MINIATURE HYBRID NARCISSUS.

(*NARCISSUS MINICYCLA*.)

THIS interesting little hybrid, reproduced life-size on this page, was raised by crossing *Narcissus minimus* with *N. cyclamineus*. The hybrid, raised from seed sown in 1908, is almost intermediate between the two parents, and a detailed description of it appeared in last week's issue on page 60 under "New and Rare Plants." An award of merit was granted to this novelty by the Royal Horticultural Society on January 21, and this, we believe, is the earliest date on which a *Narcissus* has ever gained an award. The hybrid was raised by Mr. F. Herbert Chapman of Rye, and we understand that it has now passed into the hands of Messrs. Barr and Sons, through whom it will be distributed.

LILIES: A CAUSERIE.

(Continued from page 47.)

THE many forms of *L. Martagon* are not made as much of as they deserve. Though they prefer a sunny, open border, there are few corners in a garden where they will not settle down and make themselves at home, whether it be in semi-wild grass or in thin shade under trees. The common pink type is the dullest of the forms, but even that varies greatly, and some pretty pearly pink forms, as well as deeper ones, may be selected. I should like to be in the hay meadows around Modane when the *Martagons* are ablow. I have only seen their fat buds just appearing in pendent bunches, but from the variety of colours they wore at that early stage, shading from yellowish green to nearly black, and from the variation in the amount of white down that covered some and the shining, glabrous surface of others, they promised a rich array of varieties. I did, however, secure one treasure from that neighbourhood. While scrambling on the rocky southern hillside behind a little frontier town, searching for butterflies chiefly, I espied in a garden a group of *Martagons* with curiously pale golden leaves. A closer inspection through the gaps of the fence showed it was not diseased, but a distinctly golden-leaved form. It appeared to be growing in the garden of the Douane, and, as I was not very certain then as to the attitude the officials took to the collecting and posting of plants, I was daunted, and waited to ask mine host of the inn if he could get me a bulb in autumn. This he promised to do, the Chef de Douane being his very good friend. However, no bulb came, so on my next visit I plucked up all my courage, my best manners, and what I call my French. Anything in his garden was at my

RUSTIC POLES ARRANGED IN A BED AS SUPPORTS FOR RAMBLER ROSES. SEE THE EFFECT ON THE NEXT PAGE.

disposal, but, arrived within view of my golden treasure, alas! it was not on his property. That little stone marked the boundary, and beyond it was the garden of the Barracks! I despaired; my companion said "Courage." He would conduct me to a sous-officer who directed the horticulture, and so, after much more bowing and hat-raising than I had ever achieved before in so short a space of time, the benevolent martial director of horticulture sent for a pleasant old blue-bloused gardener with a huge snake that looked as it had been cut out of a giant's pack of cards. The Lilies were attacked, and I acquired three and their history. That related how one plant was found on the mountains and, brought to the garden many years ago, had increased to form this glowing patch. Of course, it was not very good for them to be lifted just at flowering-time and sent off on the long journey to England, but I have hopes they will recover it and be as beautiful here as they appeared to be on Mount Genis. The beauties of the Martagon family are album, the pure white, and the deep claret *L. dalmaticum*. The former of these is a very old garden plant, and was praised by Parkinson as "being altogether of a fine white colour, without any spots, or but few, and that but sometimes also."

Then, as now, a form existed with flowers of a poorer quality of white, and speckled with dull purple towards the centre. Being so easily raised from seed, it is always likely that inferior forms will be found in any large stock of it; so in buying white Martagons it is best to make as sure as possible of getting those of the fine white colour. Parkinson also writes of the Blush Martagon, "whose flowers are wholly of a delayed flesh colour with many spots on the flowers." This I believe I have, and it is a very charming plant. I got it from an old garden near here that was deserted and had gone wild.

The deep purple dalmaticum is a noble Lily, but all too seldom seen. I know a garden in which a bulb of it throws up annually a 5-foot stem, bearing a great number of deep claret crimson flowers, just on the edge of a shrubbery bordering a lawn, where it looks as though it had been undisturbed for many years. I know nothing of quite the same deep colouring at its season of flowering, and it gives a fine note of colour, especially when the sunlight shines through it. Here I find it takes some years to get established and flower well. From this and *L. Hansoni* the handsome hybrid *L. Dalhousii* was raised. The blending of orange with the purple has produced a curious deep chocolate-coloured Lily more or less spotted with orange. It is not so fine a thing as *L. dalmaticum*, perhaps, but seems to possess a good constitution, and I grow a group of it in front of the *Ceanothus* mentioned previously, and like the effect of their contrasted colourings. Another wedding in the same family—that of Miss Blanche Martagon and Mr. Hansoni—has given us the various hybrids called Marhan, fine effective young people of various buff and orange shades and more or less speckled. The one known as Miss Willmott

is, I think, the best. I find they require a mulch and watering in dry weather just before coming into flower, otherwise they flag on hot days and the lower whorls of leaves do not recover, but die off and spoil the general effect. The parent *L. Hansoni* is a grand acquisition for a partially-shaded spot. It appears to be very easily satisfied as to soil, provided it is deeply planted and gets a fair share of moisture in the growing season, and its clear orange shade is wonderfully effective among Ferns and other plants with a taste for semi-shade. It is often called the Japanese Martagon, but is not of true Martagon shape, as the segments of the flower do not curve inward in the same way to form the Turk's-cap—the martagon—the form of turban worn by Sultan

THE ROSE GARDEN.

GROWING ROSES OVER RUSTIC POLES.

ONE of the most effective ways of growing rambling Roses is to train them over rustic poles. Nothing could be easier; the idea is simplicity itself, and is excellent for both large and small gardens. A glance at the two accompanying illustrations will readily explain the principle. In the first of them we see large rustic poles arranged more or less in the manner of a tripod, being wired together at the top. At the base it will be observed are

ROSE ELISE ROBICHON GROWING OVER RUSTIC POLES SIMILAR TO THOSE SHOWN IN THE ILLUSTRATION ON THE OPPOSITE PAGE. PLANTING MAY STILL BE DONE.

Mohammed *L.*, from which the name is derived, I hope the forthcoming supplement to *Elwes' "Lilies,"* of which little birds already sing in horticultural inner circles, will make clear and plain for us the at present confused identity or distinction of *L. avenaceum* and *L. medeoloides*. Mr. Grove already tells us in his little foretaste book that the figure of *L. avenaceum* in the Monograph must be taken to be *L. medeoloides*; best of all, that this little gem can be grown well in lime-free leaf-mould in slight shade. It was, I suppose, this Lily that was confused with *L. Hansoni* when that golden beauty made its *début* in English gardens.

Waltham Cross.

E. A. BOWLES.

(To be continued.)

planted rambling Roses, and these, with an occasional tie, are being trained to clothe the rustic poles. In the second illustration we see a rambling Rose in its full glory, with scarcely a trace of the rustework visible. Surely a Rambler could not be shown to greater advantage than this.

In this method of culture there are two salient points to bear in mind. In the first place, it should not be overlooked that rambling Roses, above all others, respond to deep cultivation, an important matter if it is hoped that they will attain a good height. Secondly, the poles must be made secure and well fixed in the ground; they must be perfectly rigid before planting. Roses may still be planted, but owing to the mildness of the season

and the subsequent forwardness of plant-life, we advise readers not to delay planting longer than can reasonably be helped. Any of the rambling Roses may be grown in the manner described. The wichuraianas are especially suitable, such, for instance, as Dorothy Perkins and Jersey Beauty, and the same may be said of Dundee Rambler and Longworth Rambler, to mention only a few among a multitude of others. The second illustration is that of the variety Elise Robichon, one of the best of the wichuraianas for this purpose.

SOME OF THE NEWER HYBRID TEA ROSES.

(Continued from page 59.)

Mabel Drew (Alex. Dickson and Sons, 1911).—This, an excellent exhibition variety, will fill a decided want as a good cream-coloured bedding Rose also. I have always considered, taking it all round, that Mrs. David McKee was the best Rose of its colour for this purpose and a Rose that was not half enough appreciated; but now Mabel Drew will displace Mrs. David McKee, having rather more colour in its flowers and being a more continuous flowerer. Mrs. David McKee had, it is true, three distinct periods of flower; but Mabel Drew promises to beat that, being practically in flower from June till November. Its flowers are large, of good shape, sweet scented, and held erect above good foliage that appears to be almost mildew-proof.

Mme. Segond-Weber (Souper et Notting, 1908).—This is a beautiful Rose of a good clear salmony pink in colour, free-flowering, a good grower of nice habit, producing a beautiful long bud that makes an excellent button-hole. A great favourite with me. It has a delicious perfume, and as a bedder can be strongly recommended as being the best Rose of its colour, easy to grow and with no bad fault.

Margaret Molyneux (Alex. Dickson and Sons, 1909).—This is not a Rose that will appeal to everyone; it has too few petals, being only semi-double, but at its best it is a Rose of exquisite colouring. It produces its flowers freely in trusses of three to five blooms. These should be cut quite young and allowed to expand in water. The colour varies from pale saffron yellow, shaded apricot and peach, but fades to crimson in the sun. A great favourite for table decoration.

Melody (Alex. Dickson and Sons, 1911).—This is a Rose that seems to have caught on in America grown under glass; outdoors with me in Hampshire it was quite satisfactory. The flowers are not large, but very beautiful in shape and colour, and are freely produced on good long shoots. It will prove one of our best bedding yellows, I think. It has the further advantage of being mildew-proof, and is deliciously scented.

Miss Cynthia Forde (Hugh Dickson, 1909).—I referred to this Rose under exhibition varieties, but it will take a very high place as a bedding Rose, and although there are many pinks, I am inclined to say this is the best of them all, and is to be preferred even to Caroline Testout or Lady Ashdown. It is a gold medal Rose of much merit.

Mrs. Alfred Tate (S. McGredy and Son, 1909).—This is one of the most beautiful Roses for table decoration that we have, and now that it is down to normal prices should find a place in every garden where such Roses are wanted. It also makes an excellent button-hole in the bud stage.

It has not many petals, but it keeps its shape well, and its colour is best described as coppery shaded fawn. I do not think it was ever staged for the National Rose Society's gold medal, but it has received the Royal Horticultural Society's award of merit and was awarded a gold medal at the Bagatelle Trials at Paris in 1910.

Mrs. Amy Hammond (S. McGredy and Son, 1911).—See page 580, November 23, 1912, "Exhibition Varieties." A Rose to be obtained at the earliest opportunity.

Mrs. Arthur R. Waddell (Pernet-Ducher, 1908).—Really outside the date (1909-12), but I think I ought to make a passing reference to the fine colouring of this Rose. Of neat habit, not very vigorous, it is a pretty bedding Rose; colour, deep salmon rose on copper. An excellent long-pointed bud, very useful for house decoration.

Mrs. Frank Workman (Hugh Dickson, 1911).—This is a good grower and a fine decorative Rose of good habit, flowers held erect; colour, a clear deep rose pink. Very free-flowering as seen at Belmont. It received a card of commendation at Salisbury in 1910.

Mrs. Fred Straker (Alex. Dickson and Sons, 1910).—Another very beautiful button-hole Rose, with that delightful spiral twist to the petals that gives such a look of perfect finish to the flower. Not large, but of excellent shape, very sweetly scented; a colour that varies from orange in the bud to silvery fawn in the older flower. A good, erect grower and a "fascinating" Rose for table decoration.

Mrs. Richard Draper (Hugh Dickson, 1912).—See page 611, December 7, 1912, "Exhibition Varieties."

Mrs. Wakefield Christie Miller (S. McGredy and Son, 1910).—A great Peony-like flower of bicolor tints, soft blush pink on the inside of the petal, with deep rose on the outside. A bed makes a great splash of colour, but there is not much shape about the individual flower. A robust rather than a vigorous grower, so the plants are best planted thickly. A good decorative variety for the garden.

Mrs. Walter Easlea (Alex. Dickson and Sons, 1910).—A flower not unlike Richmond and Liberty, but holding its flowers more erect than the latter variety. It is free-flowering, but I cannot say that I have found it a great advance on Richmond.

Southampton. HERBERT E. MOLYNEUX.
(To be continued.)

THE KITCHEN GARDEN.

SEASONABLE NOTES ON VEGETABLES.

Sowing Onions.—It is now regarded as necessary for every amateur and cottager to endeavour to grow monster Onions, and though they do not often succeed in producing anything beyond a modest three-pounder, failure will assuredly not come for want of strenuous efforts. It is imperative to secure a particularly fine strain of seed; but this is not difficult from the advertisers in THE GARDEN, and a fair price must be paid for it. For sowing, choose boxes about ten inches deep and fill them to within an inch of the top firmly with a mixture of loam and manure, adding sharp sand or grit at discretion. On the level surface set the seeds so far asunder that transplantation

to other boxes or a specially-prepared bed in a frame will not be required, as labour will be saved in this manner. Stand the box in a greenhouse or heated frame, and, immediately the seedlings appear, put it in a position close to the roof glass to prevent the slightest chance of drawing. From the time they are 2 inches high a cold frame is the best place, but it is absolutely essential to success that the plants shall not cease steady advance, as they never fully recover from a check, even though the cessation be for only six hours.

Horse-Radish.—It is a cause of some wonder why Horse-radish, which is so highly appreciated by many people, is so frequently a nuisance in gardens. Of course, the reason is that the plant is treated as unworthy of attention, and it quickly becomes a pestilential weed. If it were grown on ridges, a supply would always be readily at command, which is far from being the case in the generation-old bed, and the grower would feel himself in complete control of the situation. The process is simple. Cut a trench 3 inches deep and 14 inches wide, and fill it firmly with good manure. Then build up a ridge 10 inches high and 5 inches wide at the top, and insert slantingly along each side, at distances of 8 inches, whips 4 inches long and about as thick as a pencil. In the late summer and autumn there will be plenty of excellent produce to dig, and a fresh ridge can be made each season, the length varying, of course, with the demand.

Seed Potatoes.—It is most important that the tubers which are under process of sprouting prior to planting shall be kept quite cool now, or the shoots will be weak. Provide them with as much light as possible, and see that they have plenty of fresh air. If the trays are in a room with light coming from one side only, turn them daily, and if they are stacked to economise space, bring the sets from the middle to the sides at least once a week. Bear in mind that frost must be excluded from the place, or disaster is inevitable.

Early Peas.—Those who can afford the space in a frame or greenhouse should sow a few seeds of a fast-podding, dwarf, marrowfat Pea at once in boxes. A little trouble is entailed, but with proper care the results are so excellent that the return is profitable. The boxes may be 6 inches wide, 4 inches deep and of any length that may be convenient. Make provision for drainage, fill with light soil and sow the seeds thinly. To encourage germination there should be gentle heat; but, as soon as it is safe to do so after the seedlings show through, put the box in a cold frame to favour hardy progress until the plants can be put out in April. If a sowing is made out of doors of the same variety on a warm border, the plants from seeds sown under glass will yield pickings from fourteen to twenty days earlier. This last-mentioned sowing must be done before the end of the month in any case if it is within the bounds of possibility.

Longpod Beans.—It is also necessary to make a sowing of a good variety of Longpod Beans as soon as the state of the weather and the soil will permit. The plants are usually grown in double lines, and the drill, or shallow trench, for the seeds ought to be not less than 12 inches wide, the seeds being set 3 inches asunder 1 inch from the sides. When the seedlings are big enough to prove which are the best, thin them out to 6 inches. The soil covering above the seeds may be 2 inches or 3 inches deep.

GARDENING FOR BEGINNERS.

LILIUMS IN UNDRAINED PANS OF MOSS FIBRE.

THE accompanying illustration shows the good results which attended my first experiment at growing Liliums in vases of carbonated fibre without drainage, a method of culture to be recommended, provided (as is necessary with all the spring-flowering bulbs) that care is taken to avoid overwatering. The following were tried: *L. longiflorum*, *L. giganteum speciosum*, *L. Melpouene*, *L. Kratzeri*, *L. tigrinum Fortunei* and *L. auratum*, all of which flowered most satisfactorily. Further proof of this treatment suiting the Liliums was the extreme freedom with which the bulbs had rooted, so much so that, after flowering and the stems being cut down, it was difficult to remove the old bulbs intact. Probably if they had been left undisturbed and kept moderately dry until early spring, the speciosums would have again flowered well the next season.

Now is a good time to plant for this purpose, using a vase 7 inches or 8 inches in diameter; and since Liliums always emit roots from the stems as well as from the base of the bulb, they should be placed so that their tops are covered with the moss fibre at least 2 inches. Press the fibre moderately firmly, and if at all dry, moisten well. Stand either in a light or dark but cool place, bearing in mind that as the moss fibre retains moisture much longer than ordinary potting compost (especially so when undrained), no further watering will be required for several weeks. The variety shown in the illustration, *L. tigrinum Fortunei* (Giant Japanese Tiger Lily), is to be highly recommended, always succeeding either under glass or outdoors, where it thrives equally well in sun or partial shade, being especially effective when planted about two feet apart in groups. *L. tigrinum Fortunei* is considerably more handsome and vigorous than the old form of *L. tigrinum*, the growths, of which two or more are usually produced, attaining an average height of 5 feet. The moss fibre suiting all the above varieties of Liliums so well, I propose this season also trying it mixed with the same quantity of ordinary compost for pot culture; while, when planting Liliums in the open ground, it is quite anticipated that 2 inches or 3 inches of this material placed both below and over the bulbs would suit most varieties admirably. V.

require a good heat in their young stages of growth. They must be grown quickly, but, of course, not unduly forced. A day temperature of 65° and one of 58° at night answer the purpose admirably in March. Sow the seeds now in a light, sandy compost, fibrous loam and sweet leaf-soil in equal proportions serving the purpose well. Pots or pans may be used, and the drainage must

let it remain rather loose in the pans, as the water applied will firm it sufficiently. Rapid growth then results. The young plants must be repotted directly they require it, so as to induce a branching habit. Use well-rotted manure in the compost after the first pricking out of the seedlings. When buds form, feed judiciously and admit more air. The leaves form a beautiful setting to the Camellia-like flowers. SHAMROCK.

A GIANT TIGER LILY, *LILIUM TIGRINUM FORTUNEI*, GROWN IN AN UNDRAINED BOWL OF FIBRE.

HOW TO GROW BALSAMS.

WHEN well grown, a batch of Balsam plants makes a brilliant display in the greenhouse or conservatory, and are strong rivals to the tuberous Begonias. The Balsam was very extensively grown twenty years ago; then there seemed to be a falling off in the general appreciation; but of late it has again found much favour, as the plants have been proved to be useful in dry borders as well as in the greenhouse. It is a half-hardy annual, easily raised from seeds, and so there is no necessity for the wintering of stock. Although the plants will do so well in the open air in summer, they

be ample. Sow the seeds an inch apart and bury them a quarter of an inch deep. Keep the soil moderately moist and the seed-pots in a warm position; if not on the top of a hot-bed in a frame, then in a warm place on the stage in the greenhouse. The stems of both seedlings and flowering plants are succulent, and consequently a constantly saturated condition of the soil is undesirable. Transplant the seedlings early, using a similar compost to that recommended for the raising of the seedlings, and do not make it firm;

HOW TO POT TUBEROSES.

THE Tuberose, when properly treated, grows and flowers freely, but many tubers are spoiled during their early stages of growth through wrong treatment. Frequently one sees plants very tall, weakly of stem and badly flowered, many individual flower-buds not developing as they ought to. Some cultivators place the tubers in small pots, and then re-pot the growing plants in due time; others put them in the flowering pots at once. I favour potting in 3½-inch pots, and then re-potting when the pots are getting well filled with roots. Nearly every tuber possesses several "eyes" or buds on the sides. These must all be carefully picked out with the aid of a knife before the tubers are potted. If this is not done, the young side shoots grow through the soil in the pots and their removal is a difficult matter. These young shoots are valueless as regards the bearing of flowers, and if left on greatly weaken the main stem which does bear flowers.

A suitable compost is one formed of fibrous loam, two parts; leaf-soil, one part; and well-rotted manure, one part, with plenty of sand added. When the tubers are potted, some sand should be placed under and around each one. Press down the soil firmly with the fingers, and leave one-third of the tuber exposed above the soil in the pot. If the compost is moderately moist, it will be in good condition. Do not water until some roots are forming and new growth has started. If the pots can be placed on a warm base, new growth will soon commence. The temperature should range about 60° until the new stems are nearly a foot high; then more air must be admitted. AVON.

HOW TO PREPARE SOIL IN A ROSE-BED.

VERY often the inexperienced cultivator can, in imagination, see his trees growing in the bed before he plants them. He then procures the trees and plants them in dug-out holes, and the following year the growth is not very satisfactory. Before any planting is done the soil should be trenched at least 2 feet deep all over the bed, and if it is very poor a quantity of rotted manure may be mixed with the soil 6 inches below the surface. When the trees are planted, if they are standards they must be held steadily in position by short stakes and a thin mulch of litter put on. Heavy winter dressings of cold, wet manure do more harm than good to newly-planted Roses. H.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Seeds of Bedding Plants to be sown at once include *Centaureas*, *Cineraria maritima*, *Antirrhinums*, fibrous and tuberous rooted *Begonias*, *Chamaepeuce*, *Wigandia*, *Pentstemons* and *Cyperus natalensis*.

Fuchsias are among the finest of all subjects for summer bedding, and young plants rooted in the autumn and potted off singly should now be ready for another shift forward, this time into $4\frac{1}{2}$ -inch pots. By this means really good specimens 4 feet high may be had by early June.

Plants Under Glass.

Gloxinias.—Some of the older tubers should now be shaken out from the old soil, and these, if placed in shallow boxes and partially covered with very light soil, will soon begin to make growth in a warm house. As soon as sufficiently well rooted, they should be potted direct into their flowering pots.

Begonias.—Where early plants of these are desired, they may be treated as above, but they should not be started in quite so much heat as *Gloxinias*, an intermediate temperature being more in keeping with their requirements.

Caladium Argyrites and other small-foliaged varieties may also be started in boxes, potting off as soon as the young growths get an inch or so high. Quite small bulbs make the best plants eventually, if care is taken to give a slight pot on when necessary.

Seed-Sowing.—Various seeds should now be sown, including *Begonias*, *Gloxinias*, *Streptocarpus*, *Medeola*, *Grevilleas*, *Dracena australis* and *Asparagus plumosa* and *A. Sprengeri*. Needless to say, great care is necessary in the sowing and attention to the smaller seeds, and these should be covered with glass in the propagating-frame till the seedlings appear above the surface.

Propagation by Cuttings.—Various occupants of the stove root readily at this season, and cuttings of *Crotons*, *Dracenas*, *Panax*, *Pandanus*, *Panicum*, *Acalyphas* and *Dieffenbachias* should be got in as space in the propagating-frame permits. A quick-rooting compost of peat, leaf-soil and silver sand should be used for the above subjects, placing the cuttings in small pots with a fairly warm bottom-heat. Most of them should be ready for removal in from fourteen to twenty-one days.

The Rose Garden.

Manure-Water.—During mild weather liquid manure from the farmyard tank may with advantage be given to the Rose-beds. At this season the ground will take it much more readily than during the summer, and if the tank is emptied after rain, there is not much danger of the liquid manure being too strong. It may seem superfluous to apply liquid at this season of the year, but it is certainly making good use of manure which would probably be wasted.

Freshly-Planted Trees.—Look well after these, treading the soil well about them after frost. Teas and others that may have been protected by having the soil drawn up to them should be looked over occasionally, the unusually mild fore part of the winter having kept them in a very soft condition, and I have noticed that it is the later frosts which do the most damage.

The Kitchen Garden.

Ground Work.—Press on with this as long as the weather keeps open, reserving such work as preparing stakes and binning rubbish till frost drives one off the ground.

Preparing Composts for Frames.—This is another of the jobs that can be done during wet or even hard weather, providing a good open shed is available. Old hot-bed material, Mushroom manure, well-decayed leaves, wood-ashes and a fair proportion of loam will make a good compost for growing Carrots, Lettuce, Turnips, Beans and Potatoes in frames, keeping it under cover, if possible, till it is required.

Spring Cabbage.—Fill up any blanks during favourable weather and give the bed a good hoeing occasionally, the loose surface allowing the soil to get the full benefit of whatever sun there is. The same remark applies to any other growing crop, such as autumn-sown Onions and Spinach.

Fruits Under Glass.

Vine Borders.—By this time some of the earlier-started houses with inside borders may be requiring water, and though they must not be allowed to continue dry, care should be taken to apply water only when the outside conditions are favourable. Although I do not think that water straight from the tap later on in the season is at all detrimental, it is safer at this season to apply only water that has been standing in the house some time, or by some other means has been raised to a temperature of from 55° to 60°, this, of course, only applying to houses containing Vines forward in growth. Vines in houses that are being shut up will not be hurt by using cold water.

Disbudding Peaches and Nectarines.—The earliest trees will probably be pushing into good growth rather quickly now, and as soon as the shoots are forward enough to handle, disbudding must commence. Nearly every grower will have his own system of disbudding, but I would point out that to keep the trees well furnished it is quite necessary to encourage young growths as far back on the old wood as possible.

Pot Trees.—Very little disbudding is necessary with pot trees, but to keep them as small as possible the shoots on last year's growths may be rubbed off down to where the fruit is nicely set, and some of these may even be taken off the extremities of the shoots, thereby diminishing the size of the tree, the remaining shoots being stopped as necessary to build the tree and to concentrate its energy into the fruit.

The Hardy Fruit Garden.

Gooseberries.—These are breaking into growth uncommonly early, and pruning should be undertaken at once. Nothing is gained by having the trees too thick, a well-trimmed tree generally carrying a good crop and being much easier to gather the fruit from. In nearly all instances, Gooseberries have to be protected from the birds, and where they are not enclosed in a wire cage, the trees, after pruning, should be sprayed with a fairly strong solution of soft soap, immediately afterwards giving them a good dusting all over with quite freshly-slaked quicklime. I have never known this to fail to keep the birds from taking the buds.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Adlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Antirrhinums.—These popular flowers now play an important part in our gardens, whether large or small. They have much to recommend them, being inexpensive, easy of cultivation, highly floriferous, having a long flowering period, and furnishing a great variety of colour. They should be sown within the next ten days in boxes in moderate heat, and pricked off about two inches apart as soon as the first pair of rough leaves are formed. They can be had tall, medium and dwarf. The mediums are the most useful, and the following can be recommended: *Carmine Pink*, *Bright Pink*, *Delicate Pink*, *Apricot*, *Orange King*, *Fire King* and *Brilliance*; also crimson, yellow and white selfs.

Propagation by Cuttings.—The propagation of bedding plants by cuttings should now proceed apace. These will include *Geraniums*, *Paris Daisies*, *Ageratums*, *Heliotropes*, *Lobelias* and *Salvias*. *Geraniums* must, of course, have abundance of air, but all the foregoing will root readily whenever they can have the benefit of a brisk temperature with plenty of moisture and a close atmosphere.

Jasminum nudiflorum.—This attractive winter-flowering wall plant will now be out of bloom, and should be pruned forthwith. Cut away a number of the old shoots to make room for the young growth, as it is on this that the next winter's crop of bloom will be borne.

Polygonum baldschuanicum.—This native of Western Asia is one of our most accommodating plants, being equally at home on a wall, a pergola, or the front railing of a villa. If not already done, it should be pruned now, but not too closely;

say, to within 6 inches or 8 inches of the framework of the plant. The plant yields two crops annually of its graceful panicles of pale pink flowers.

The Rose Garden.

Late Planting.—Where from some unavoidable cause planting must be delayed beyond the normal period, the plants should be lifted now and heeled in behind a north wall or hedge to retard growth, so that the plants shall not be unduly checked when planted in their permanent quarters.

Stocks for Standards.—Those who propose to work stocks for standards or half-standards should search the hedgerows for suitable material and have them planted and staked in the reserve garden.

Plants Under Glass.

Slugs, like the poor, are ever with us. They are very partial to the blooms of *Dendrobium* and *Cœlogynnes*. At night, by the aid of a lamp, is the time to catch them red-handed.

Zonal Pelargoniums.—Those that flowered during the autumn and early winter, if cut back now and rested for a few weeks, will make a brave show during the summer. Prior to cutting them back, the points of the shoots should be utilised for cuttings for next winter's supply.

Fruits Under Glass.

Ventilation.—This should receive very careful attention, for three good reasons: First, shade and sunshine alternate very rapidly at this season; secondly, there is great disparity between the external and internal temperatures; and, thirdly, whenever growth is active it is succulent and tender, and therefore highly susceptible to sudden fluctuations of temperature. Admit air gradually, at the top first, and never at the top and front or sides at the same time. Very little front or side air will be required for some weeks yet.

Melons.—When the first batch has made 3 inches of growth, the pots should receive a top-dressing, care being taken that the soil has been warmed to the temperature of the Melon-house before being applied. A successional sowing should now be made.

Peaches.—Where these have just set their fruit, they should be vigorously syringed to remove all decaying flowers and cleanse the foliage. A rather higher temperature may now be maintained.

The Hardy Fruit Garden.

American Gooseberry Mildew.—Although I have had no personal experience of this virulent disease, I would remind readers that the Board of Agriculture recommend that whenever there is any suspicion of the presence of the disease, the bushes should be sprayed with Bordeaux mixture about a fortnight before the buds begin to open, and, should rain occur soon after the operation, it should be repeated.

Strawberries.—Where late runners were taken and planted in nursery lines, they should be planted in their permanent quarters as soon as possible. The rows should be from 2 feet to 2½ feet apart, and the plants 12 inches to 15 inches apart in the row, according to the vigour of the variety.

The Vegetable Garden.

Broad Beans.—A sowing of these should now be made on a south border, and for this sowing *Early Mazagan* is the best. It will be advisable to coat the seeds with red lead, and a little wood-ash should be scattered along the drills; 2 inches is deep enough to plant.

Rhubarb.—Where young plantations are to be made, the work should be carried out as soon as convenient. The ground should be trenched and well enriched, as Rhubarb is a gross feeder and is being continually robbed during the growing season. *Daw's Champion* and *Victoria* are two excellent varieties.

Mint.—The Mint-bed should receive a top-dressing of some light, rich compost for the young roots to feed on.

Lime.—Although not a fertiliser, lime is valuable as a liberator, and most garden soils, if at all heavy, are benefited by light dressings of it. Some ground lime should therefore be ready for the approaching spring weather.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mains, Midlothian.

A NATIONAL DAFFODIL SOCIETY.

THE letters of Captain Kitchin and Mr. Carne Ross, which have recently appeared in THE GARDEN, seem to point to a feeling which I entirely reciprocate, viz., that the time has come when steps should be taken to see if a National Daffodil Society could not be formed. My reasons are as follow:

1. As Mr. Carne Ross says, the Daffodil is to-day too important a flower in the economy of the garden to be run as a side-show, even of such an august society as the Royal Horticultural Society. I put it a little differently and say it does not seem to me that we are giving it the honour to which its merits and commanding position entitle it, when we do anything less than put it upon the same level as the Tulip, Rose, Carnation, Auricula, Chrysanthemum, Sweet Pea and Gladiolus, which are all enjoying at the present moment the dignity of a "National." This sentimental reason is with me a very strong one, and if others feel it in anything like the way I do, it will not be long before it is a *fait accompli*. *Carthago est delendum*. A National Daffodil Society must be formed.

2. This feeling of mine would not be in the least altered if I had found after nearly two years' trial that the Royal Horticultural Society had done all that was expected of it in regard to the Daffodil. In my humble opinion it has been tried and has been found wanting. I write this in no fault-finding spirit. I state it as what appears to me to be a self-evident fact. The Royal Horticultural Society lets its hall to the cats and the cooks, and they do not, I suppose, expect it to run their shows for them; why should the poor Daffodil? It is not the function of such a society to "run" one flower more than another. I look upon it as the mother of all flowers, fruits and vegetables, and I do not think it should have a favourite child. Years ago, when valentines were in fashion, I received one from a dear old aunt of a hen surrounded by chicks, with the inscription, "I long to take you under my wing." I think this would not be a bad crest and motto for our great society. It so exactly hits off its function as nurse and protector, even to the ugly duckling, if the necessity should arise.

3. I give a concrete example of what I mean by its not being the function of the Royal Horticultural Society to run the Daffodil. As readers know, a Daffodil show was held in 1912, and I presume another is to take place in 1913; but up to the present (January 27) I have had no schedule sent to me, nor can I hear of anyone who has. Some little time since I hinted to one of the powers that be that if there were any schedules they should be sent round at once, as we ought to have had them *last July*. The reply I got was something as follows: "Send them round! Who to? Let people apply if they want them." Yes, who to? All Daffodil-lovers! How can the Royal Horticultural Society know them even if it wanted to send them all a schedule? Then take the second part of the reply, "Let people apply if they want them." How are people to know that there is to be a show in 1913? How are people to know that they may or must apply if they want a schedule, or they will get none? For the Royal Horticultural Society to expect this (and I presume from its action in this matter it does do so) is to expect the cart to pull the horse.

4. By retaining the Barr Cup in its own hands the committee of the same looked forward to a time when a national society would come into being. As a member of that body I think I may say that should such an event take place, it would then hand over the cup to the national society. This is one reason, but only a small one, for taking the step I am advocating. More weighty ones are the necessity for legislation, for guidance, for information, for fostering care, and last, but far from least, for leadership. These things are wanted in the Daffodil world. There is a void in the life of the Daffodil fancier which legitimately calls upon someone or something to fill it. But there is no one to hear.

5. I venture to suggest a meeting of Daffodil people to talk all this over on the morning of the second day of the Spring Bulb Show—that is, on Wednesday, March 5. *Carthago est delendum*

JOSEPH JACOB

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—*The Editor intends to make THE GARDEN helpful to all readers who desire assist- ance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

WIRE FOR SWEET PEAS (*Nubian*).—You should unhesitatingly give the preference to *Simpliciter* galvanised iron wire for your Sweet Pea supports, choosing that of the finest procurable quality. Yes; horse-mannure from animals bedded in sawdust may be advantageously used.

INJURY TO ANTIRRHINUMS (*N. W.*).—You think the Antirrhinums are suffering partly from slug attacks, but at the same time there is apparently a fungus, a species of *Septoria*, attacking the foliage. We recommend you to try spraying with potassium sulphide at the rate of 1oz. to three gallons of water. If this does not check the trouble, write to us again, giving full particulars of the mode of cultivation and sending further specimens.

PLANTS IN BOXES (*H. R. R.*).—The following plants will be likely to thrive in your boxes: Front box—*Hypericum calycinum* (evergreen, St. John's Wort); second box—a mixture of *Aucuba japonica* and *Berberis Aquifolium*, both evergreens; third box—*Jasminum nudiflorum*; and *Ampelopsis Vetchii* to grow on the wall. It will be necessary to drain the boxes well and provide really good loamy soil in the first instance. If the leaves become very dusty, syringe them occasionally with soft-soap water, followed by clean water.

FLORISTS' FLOWERS (*F. H. W.*).—The florist's type of *Ranunculus* is not now in general favour, and the most likely reason is that public tastes alter as time goes on, as instance the decline of *Balsams* and *Hyaconthis* and the increasing popularity of *Carnations* and *Narcissus*. Mr. T. Smith of Newry, Ireland, or Messrs. Barr may be able to supply named varieties, while a post-card would secure a catalogue from any of the bulb-merchants advertising in THE GARDEN. Some of the Auriculas you mention are old kinds and not in general cultivation. *Smiling Beauty* was exhibited in 1877 by the Rev. F. D. Horner at the Crystal Palace in his first-prize set of twelve, but is now probably superseded by others. *Acme* is one of the best white-edged Auriculas. It has been exhibited 141 times in winning stands at the London shows during the last ten years, which is a first-rate testimonial. Sunshine we do not know. *Sapphirae* has a pale yellow tube, white paste, and violet blue edge. Mrs. Potts has a margin of violet, but the stem is weak; and *Favourite* is, no doubt, the finest of those with a violet edge. There is not much to choose between *Henry Wilson* and *Shirley Hibberd*. Both are good; personally, we prefer the latter. Auriculas have produced more autumn flowers than usual, and growth

has commenced earlier this season owing to the exceptionally mild weather. A second-hand bookshop is a good hunting-ground for old books, but an advertisement in THE GARDEN would no doubt bring you some replies, as such books as you require are somewhat scarce.

DELPHINIUM SEEDLINGS (*L. B.*).—So far as hardiness is concerned, the seedlings need no protection whatever, and a frame is frequently harmful, in that it harbours slugs, unless these are well looked after. You may certainly put the seedlings into the frame, but first place in a few inches of coal-ashes and so raise the boxes that the plants are kept near the light. Do not close the frame entirely; allow plenty of air day and night. Dust the plants and the frame with a little fresh, dry soot, and it will render the seedlings distasteful to the pest. Early in March plant them in rich, deeply-prepared garden soil, allowing about two feet between the plants for development. Thus treated, the plants will stand for two or more years. We much regret that your letter has been mislaid.

PLANTS FOR BORDER (*E. Chester*).—For a tall plant you could not plant anything more suitable than the Sweet Pea in white, blue, mauve, cream and pink shades. This would hide the wall and give you a display of flowers for many weeks. Prepare a deep trench of soil now 2 feet from the wall and sow seeds early in March. As the wall is of red brick, the scarlet shade of Sweet Pea should be avoided. In front of the Sweet Peas white and pink *Lavateras*, Rocket Larkspur, white *Tulocera*, tall *Antirrhinums* in several colours, *Helianthus cicuterifolius*, *Nigella*, *Calliopsis* in variety, Poppies and the like should appear; while nearer the front *Asters*, *Stocks*, *Lanums*, *Chrysanthemum coronarium* in variety, *C. curvatum*, Sweet Sultan, intermediate *Antirrhinums*, *Statice sinuata*, *Pheo Drummondii*, *Mignonette*, *Margherita*, *Candytuft* and other things should be seen. The *Antirrhinums* would be best obtained as small plants in March; the others could be sown quite thickly in their positions. If you bought a few dozen plants of *Penstemon* and *Salvia Glory of Zurich*, a brilliant effect would be secured till the arrival of frosts. The young plants are very cheap.

THE GREENHOUSE.

ALBUCA NELSONII (*Seeker*).—A pot 7 inches in diameter will be quite large enough for the *Albuca*, and if the bulb is too long to bury it completely, it will be better to leave an inch of the upper part above the ground than to use a larger pot.

AZALEA MOLLIS DROPPING ITS LEAVES (*H. A. C.*).—The dropping of the leaves of *Azalea mollis* clearly indicates some error of culture. Perhaps the plants are kept too wet or too dry, or it may be owing to their having been potted just before they were taken into the greenhouse, so that the roots had no time to take possession of the new soil.

ACACIA ARMATA LOOKING BARE (*H. A. C.*).—It is quite probable that the *Acacia* had, previous to your purchasing it, been grown in a higher temperature than that in which it now is, and this would be sufficient to account for the leaves dropping. Excesses of drought or moisture and great fluctuations of temperature might also play a part in the matter.

LILIES OF THE VALLEY AFTER FORCING (*H. A. C.*).—These Lilies of the Valley that have finished flowering may be kept in the greenhouse or placed in a frame where they are safe from frost. They must be watered as before. Then in May they can be planted out in a prepared bed, taking care they are not allowed to suffer from the want of water during the summer. Even then they will be two or three years before they flower freely, and for this reason those that have flowered in pots are very often thrown away.

CYCLAMEN AFTER FLOWERING (*H. A. C.*).—After the Cyclamen have done blooming they must still be kept in the greenhouse, watering them as before till the leaves turn yellow, when they must be kept drier, and when totally dormant, water must be almost discontinued. When space in the greenhouse is a consideration, the plants may later on be turned out into a frame; but at present the risk of severe frosts is too great to do this. When dormant they may be kept almost dry till midsummer, when they should be shaken clear of the old soil and repotted in a mixture of loam, leaf-mould, broken brick rubble and sand. After potting they must be watered sparingly till growth recommences. The best place for them during the summer is in a frame where they are shaded from the direct rays of the sun. In hot weather frequent sprinklings are very beneficial. Plenty of air should be given, but the lights must be put on in the event of heavy rains.

CARNATIONS DISEASED (*Stockport*).—The "chocolate-coloured blisters" on the leaves of your Carnations are due to the presence of the so-called "rust," in reality a fungus vegetating and first developing within the cuticle of the leaf. Unfortunately, Carnations, like ordinary mortals, are prone to a variety of diseases, and the past wet and stultic season in conjunction with a mild winter has been most favourable to their development. Usually a rather dry, buoyant atmosphere—that created by warmth and a free ventilation—will, with careful cultivation and studiously avoiding heel watering or syringing, prevent any undue spread of the disease. In other words, moisture, and that phase of moisture which is the outcome of a close, stuffy atmosphere, favours its growth, while dryness is opposed to it. If, therefore, you maintained a temperature of 55° with an on night and day at the roof ventilators, all moisture would be dispelled and the plants presently brought into a fresh, clean growth.

Salt in solution is fatal to it, but this would also be fatal to the plants if allowed to penetrate to their roots. You had better wet the "blisters" with the aid of a camel-hair brush. Dissolve a tablespoonful of common salt in a pint of water and employ it thus, or, if this is likely to prove too tedious an operation, get a small piece of sponge or even cotton-wool and, having wetted it in the solution, wipe the leaves on both surfaces. By frequently rinsing the sponge in the solution, the germs will be retained and destroyed. Some varieties are nearly, or quite, immune from rust; others take it badly. Continued greenhouse treatment on intelligent lines as suggested will accomplish much, and unless the plants are now overwhelmed by the rust, they will, with longer and brighter days, grow out of it.

PRIMULA MALACOIDES (*M. S.*).—We cannot understand your lack of success in the culture of *Primula malacoides*, as it is, in a general way, so easy to grow. The fact of the crowns damping off would suggest that the plants had been kept too close or fed too much with stimulants. Despite the fact that you say feeding was not overdone, we are inclined to think that this is at the root of the trouble. A quantity of beautiful plants came under our notice a short time since which had been given no stimulants whatever. The seed was sown in the spring and the plants grown in a frame throughout the summer, their final potting being into pots 4½ inches and 5 inches in diameter. The compost in which they were potted was made up of loam, leaf-mould and sand, no manure being employed. We would suggest that next season you treat yours in the same way, and we do not then think that you will have any further trouble in the matter.

PRIMULAS (*B. F.*).—The *Primula* that sets up a form of eczema in some persons who handle it is *P. obconica*. While it is most irritating to many, others are totally unaffected by it. This species does not form a regular crown as in the Chinese *Primula*, but produces a dense tuft of radial leaves. The blade of the leaf is broadly oblong, with a heart-shaped base, and it is not lobed as in the Chinese *Primula*. The flowers, which are borne in clusters on stalks from 6 inches to 9 inches or thereabouts in height, vary in colour from white to crimson through various intermediate shades, though in the original species they were of a soft lilac tint. A description in words is a difficult matter, but we have no doubt that you will be able to recognise *P. obconica* from what we have said. With regard to the *Aconites* and *Snowdrops*, you do not say when they were planted, a likely cause of failure being that they were kept out of the ground too long. They ought to be planted in September or, at the latest, in the first half of October. In a fairly good sandy loam they should give no trouble whatever. No mulching of manure is needed.

SCHIZANTHUS (*C. M. L.*).—In order to obtain good flowering plants of *Schizanthus* in April and May, the seed should be sown in September and the plants grown on in a light, airy house, where they are safe from frost. Above all things, avoid a warm, stuffy atmosphere, as the royal road to success is to induce the plants to grow stoutly and sturdily from the first. They may be wintered in pots 4 inches in diameter, and should be pined once or twice according to the habit of the plant. Pots 6 inches in diameter are very suitable in which to flower them, though extra vigorous ones may, if required, be put into 8-inch pots. Good loam, with an admixture of well-decayed manure, leaf-mould, and sand will suit them well. While the seed should be sown as above for early flowers, if sown now the young plants will come on quickly and afford a good succession to the autumn-sown ones. The main thing is to grow them sturdily from the first. In a temperature of 50° to 60° the seeds will quickly germinate, and as soon as this happens the young plants must have plenty of light and air. When potted off they will need to be kept closer, and perhaps shaded for a few days, till the roots take possession of the new soil. For pot culture all are good, but the large-flowered, compact hybrids and *wisetoniensis* are among the best if dwarf plants are required.

ROSE GARDEN.

PRUNING ROSES (*J. C. F. M.*).—The variety *Juliet* should have the growths that were produced last summer pruned back to about a foot in length. You will notice there were two growths—that made before the first bloom and that made after. It is the first growth we refer to. Do not peg down the Austrian Briar, but just leave the plant quite unpruned. It will bloom best on the small wood made last season.

SULPHATE OF IRON FOR ROSES (*Mrs. T.*).—Undoubtedly sulphate of iron is good for Roses, but how far it may be applied in conjunction with the artificial manure you mention would depend upon an analysis of the article. It is generally looked upon as the best fertilizer for Roses grown under glass. In an analysis made of the composition of a *Rose* plant it was found that iron was present in the roots, 2.86; wood, 4.23; leaves, 2.19; and flowers, .97. Probably the fertilizer already contains a large proportion of iron. Instead of using it we should advise making some liquid manure with soot placed in a peck bag and steeped in a cask. Another cask could be prepared by steeping some sheep-manure (this also in a bag) and giving the Roses alternate waterings with it as soon as the flower-buds are visible. The liquid could be applied about twice a week, and at first it should be diluted to half strength. We have found Wakeley's Hop Manure also an excellent aid to colour in Roses out of doors, and we should say it would be beneficial to pot Roses, but a great deal depends on how you have used the patent fertilizer you mention. We certainly do not recommend either to be used in conjunction with it, but

if the fertilizer was added to the soil at the time of potting or has been given as a top-dressing, then you can refrain from using any more of it and give the Roses the others as mentioned when the flower-buds are forming, but not after the colour is visible.

FRUIT GARDEN.

WALNUT TREE BLEEDING (*J. W. T.*).—It is very difficult to stop the bleeding. It will stop naturally as soon as the tree begins to grow. We presume there has been no fermenting manure or leaves placed near its roots to disturb the normal winter condition of the sap? The likeliest way to stop it is to scar up the surface and so close up the pores of the sap, afterwards tarring with a thick coat of gas-tar.

APPLE TREE NOT BEARING (*Sutton-in-Ashfield*).—Take off the turf all round the tree for a distance of 3 feet from its stem. Break up the surface of the soil about an inch deep, and scatter over it about a quart of bonemeal, and then surface-dress the ground with a barrow-load of good farmyard manure, spreading it evenly over the surface round the tree. Your tree does not want root-pruning. Blue dust has but little manurial value; all the same, it does good when mixed with the soil, especially if the soil is heavy.

SWELLING ON THE RODS OF VINES (*G. B.*).—It is not often one comes across a wart or swelling on the stems of Vines, and there is no known cause for its appearance. It does not injuriously affect the health or fruitfulness of the Vines according to our experience, and the best way of dealing with it is to cut out the swelling with a sharp knife level with the bark of the Vine, and the bark will then grow over the wound. It is too late to cut it out now, as the sap will soon be on the move and there would be danger of the Vines bleeding.

KITCHEN GARDEN.

EARLY LETTUCE (*Oxon*).—As you possess a heated glass structure, we advise you to sow seeds of the varieties Tom Thumb Market and Early French, a *Cos* Lettuce, at once in shallow boxes filled with rich soil. The resultant seedlings should be transplanted in other boxes 6 inches deep, also filled with rich soil, 8 inches apart. Sow seeds again early in March, and then seeds in the open border in April. The seedlings from the early March sowings may be grown in the frame. For next winter sow seeds of Hucks' Hardy White and Black-seeded Bath in August, and again at the end of September. Some of the seedlings may be grown at the foot of the walls—9 inches from them—and some in the cold frame. In January, February and March sow seeds of those varieties named above in boxes again. Paris White is a grand summer *Cos* variety.

HERBS (*M. E. F.*).—In addition to the herbs and scented-leaved plants you enumerate, the following may be expected to thrive in your garden. Providing the soil is moderately good and loamy, it will suit all; but if poor, it ought to be enriched by the addition of well-rotted manure or better soil. Aspect is of little consequence. Balm (*Melissa officinalis*), Marjoram (*Origanum Marjoram*), Horehound (*Marrubium vulgare*), Tarragon (*Artemisia dracunculoides*), Wormwood (*Artemisia Absinthium*), Southernwood or Lad's Love (*Artemisia Abrotanum*), Sweet Basil (*Ocimum Basilicum*), Chamomile (*Antemisia nobilis*), Hyssop (*Hyssopus officinalis*), Pennyroyal (*Mentha Pulegium*), Peppermint (*Mentha piperita*), Apple Mint (*Mentha rotundifolia*), Honey Balm (*Melittis Melissophyllum*), Rue (*Ruta graveolens*), Summer Savory (*Satureia hortensis*), Winter Savory (*Satureia montana*), Tansy (*Tanacetum vulgare*), Lemon Thyme (*Thymus Serpyllum* var. *citriodorus*), Cotton Lavender (*Santolma Chamæcarypatris*) and the Sage Brush (*Artemisia tridentata*). In addition, such things as Parsley, Chives, Chervil, Borage and Fennel can be admitted if you wish. All are obtainable at a moderate price from any of the leading nurserymen.

MISCELLANEOUS.

ST. MARK'S FLY (*P. C.*).—The dark grey grubs are the larvae of the fly which appears so commonly in gardens about St. Mark's Day, whence it has gained the name of St. Mark's fly. The grubs feed usually on the decaying leaves and so on in the soil, but when these are not to be had, they will attack roots of plants. They are perhaps more abundant in rather damp situations than elsewhere, but do not confine themselves to these positions. The best thing to do, if they are damaging the roots of any particular plant, would be to put a little lime or Vaportite or some similar soil fumigant about their roots.

IMPROVING THE SOIL (*Atwinna*).—You cannot do better than bastard-trench the soil and thoroughly mix basic slag and long manure with it, not putting the manure in layers. Leave it as rough as possible in the hope of frost, but do not mix the manure and the basic slag; let them lie on the surface. As soon as they come into contact they must be buried. Potash salts will be quite unnecessary, for the soil contains abundance of potash, which the lime in the slag will set free. Another season the digging should be done in autumn, and it would be well to give a dressing of ground quicklime at the rate of half a bushel to the square rod at the same time. The value of lime and of the pulverising action of the frost cannot be overestimated when clay soils are being dealt with. Indeed, we should almost think it would be better to get the soil into thoroughly good heart before any permanent planting was attempted, for with the present conditions little can be expected from it. Is the drainage good?

LEMONS GROWN IN FRAME (*E. F. K.*).—We do not say that it is impossible to grow Lemons a pound in weight in a cold frame, but, considering the dull, cold weather of last year, it would be a difficult task. There is a variety of Lemon called Metford's Lemon which sometimes perfects fruits over two pounds in weight when the plant is cultivated in a warm greenhouse, and very large Lemon and Citron fruits are ripened every year on plants growing against an outdoor wall in a Falmouth garden. Perhaps you could get the gentleman who has grown the fruits to let you see them.

BUILDING AND HEATING A RANGE OF GLASS-HOUSES (*E. T.*).—At least a 12-foot run of wall or trellis space per tree would be necessary in the case of Peach trees. To accommodate seven trees on the back wall and a front trellis, a house 50 feet long would be required. The front trellis should be curved, so as to admit light over it to the trees on the back wall. A house 10½ feet wide would be suitable. The Vines should be planted 3 feet apart at nearest; a house 30 feet long would answer for eight Vines. A forcing-house in the centre, 12 feet long and 10 feet wide, would do very well. The vinery should be 12 feet 6 inches wide. We are presuming that your houses would be lean-to. If so, the front wall of the Peach-house should be 20 inches high, with ventilation in it, and at the top of the rafters also. The front wall of the vinery should be 18 inches high, with front glass on it 2 feet 6 inches high, with ventilators in it and also top ventilators. The front wall of the forcing-pit may be of similar height, the glass portion also corresponding to that in the vinery. Good bricks usually cost about thirty-two shillings per thousand, and they are laid at an average cost of 10s. per thousand. You can thus get to know the cost of the walls, with the mortar and sand required, from a local builder. The cost of the wood and glass per foot run would be about ten shillings in the case of the Peach-house, and 15s. in the case of the forcing-house and vinery. It would be advisable to fix the boiler near the forcing-house, and to have two flow and two return 4-inch pipes round it. One flow and one return pipe would suffice in the Peach-house, and two flow and one return pipe in the vinery. A check-end saddle boiler would be the best to fix, with rings and rubber joints for the pipe connections. A local plumber could then fix the pipes, but we advise you to give the sizes of the houses (when you have decided on them) and the length of piping in each to hot-water engineers advertising in THE GARDEN, and ask for the lowest estimate with specifications. If you will refer to THE GARDEN, page 49, issue January 25, you will find useful hints on planting Vines. The Peach trees should be put in a firm soil, well drained, fan-trained trees being the best.

NAMES OF PLANTS.—*W. S., Hatwick*.—1, *Selaginella Braunii*; 2, *Helix Soleritii*; 3, *Selaginella caulescens*; 4, *S. kraussiana*; 5, *Ficus radicans variegata*; 6, *Cæsuloplia species*; 7, *Chlorophyllum elatum*; 8, *Sempervivum prealtum*; 9, *Adiantum formosum*; 10, *Gymnogramme japonica*.—*A. D. Groves*.—*Cottonaster Simonsii*.

NAMES OF FRUIT.—*Market Harborough*.—The Apple is Roundway Magnum Bonum. It should do in your soil.—*271, J. B.*—The Apple is Baldwin's, and of no value grown in this country.

SOCIETIES.

THE NORTH OF ENGLAND HORTICULTURAL SOCIETY.

The close of the second year of operations shows a paid-up membership of just over five hundred Fellows or members, sixteen affiliated societies and a turnover of £650. The increase in Fellows is nearly fifty per cent., and the number of affiliated societies has been doubled. The society is still handicapped by its heavy initial expenses, but in the coming year income and expenditure are expected to be made to balance each other. This year should see a great movement forward, as very few Fellows or members have fallen out of the ranks except by death or inability to attend shows, and an appeal is to be made on a large scale. Various special sub-committees are taking matters in hand with keenness, chief among which is the new magazine committee, which will run the magazine on the "round table" method, there being sub-editors from each of the four main committees of experts, besides a chairman (Professor R. S. Seton) and a printing and advertisement secretary (Mr. T. H. Hamit). The annual meeting will be held at the Queen's (Midland) Hotel, Leeds, on Wednesday, February 19, at 5 p.m.

WARGRAVE AND DISTRICT GARDENERS' ASSOCIATION.

A good number of members assembled on Wednesday evening, January 29, to hear a lecture by Mr. T. Tunbridge, F.R.H.S., head-gardener to S. C. Davies, Esq., The Three Elms, Kettlewell, on "The Pruning of a Few Groups of Roses." These consisted of the following: the multitoria, wichuriana, Nisette, Tea and China sections. Most minute details were given for the time and manner of pruning in autumn pruning to spring pruning in the above-mentioned groups. A splendid discussion ensued, and many questions were asked the lecturer. These he kindly answered. A hearty vote of thanks was accorded Mr. Tunbridge at the close, being carried with acclamation.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

NOTES OF THE WEEK.

Orchids Destroyed at Kew.—Those who love flowers, and particularly those who enjoy the rare kinds that are always to be found at Kew, will learn with indignation that a number of Orchids were destroyed during the small hours of Saturday morning last. We understand that an envelope bearing the words "Votes for Women" was left among the broken plants. A great deal of the glass in the three houses was broken and a number of plants hacked to pieces.

The Rev. W. Wilks.—As we have already pointed out, this week the Rev. W. Wilks completes twenty-five years' hard and valuable work for the Royal Horticultural Society as secretary. We had intended publishing his portrait, with some particulars of his work, but after hearing his speech at the annual dinner of the Horticultural Club, where he stated that he positively disliked such attention being drawn to him, we respect his wishes and allow his work to speak for itself.

Sir Trevor Lawrence, Bart., K.C.V.O., whose portrait we have much pleasure in publishing on the following page, has been president of the Royal Horticultural Society for the long period of twenty-five years, a position he has admirably filled to the benefit of the society and horticulture in general. Sir Trevor has not been merely a president in name; throughout the whole of his presidency he has attended almost every Council meeting, where his vast and intimate knowledge of horticulture has proved highly beneficial. We understand that, owing to the work now being beyond his strength, Sir Trevor contemplates resigning his position, a resolution that we feel sure all who know him will deeply regret.

Primula denticulata.—This is one of the earliest of the hardy Primulas to flower. In many rock gardens and borders its heads of dense lilac flowers are already showing colour. It is a native of the Himalayas, rather like *P. capitata* in habit, but the flowers are larger and of different colour. This Primula is particularly effective when planted in breadths in short grass about the alpine garden. It likes a moist position. The varieties alba and cashmeriana are well worth growing, the latter having violet flowers with yellow eyes.

Royal Gardeners' Orphan Fund.—The annual meeting of this excellent Fund, held on Friday of last week, ended in a most satisfactory way for the whole of the candidates that were nominated for election. No fewer than twenty-five cases of motherless and fatherless children, all of them of a most distressing nature, were brought forward. Nineteen children were elected in the usual way, and the remaining six were placed on the funds in anticipation of the forthcoming grant from

the Royal International Horticultural Exhibition. We commend this Fund to the notice of our readers. Full particulars may be had from the secretary, Mr. B. Wynne, 19, Bedford Chambers, Covent Garden, London, W.C. A report of the proceedings at the annual meeting will be found on another page in this issue.

Narcissus Golden Spur for Pots.—This comparatively old variety, just now at its best in the conservatory, is one of the finest and brightest of the early-flowering Narcissus for growing in pots. Its medium-length, sturdy flower-stems support the brilliant self yellow flowers in a graceful manner, and if well grown, wire or other artificial supports are not needed. Golden Spur is equally as valuable in the outdoor garden, creating a bright splash of colour early in the year such as we get from no other variety just at that time. The market-growers fully appreciate its value for forcing.

Apple Lane's Prince Albert for Dessert.—It is difficult to understand why this useful Apple is not more extensively grown, for it has much to commend it. The trees usually start to crop when young, produce fruit regularly every year, and the Apples can either be used for cooking or dessert. We have been using some for the latter purpose since the early days of January, and although they cannot be compared with Cox's Orange Pippin, Ribston Pippin, or others of that class, they are far superior to most of the Colonial Apples with which our shops are at present flooded.

When to Prune Winter Jasmine.—We so often see this beautiful winter-flowering shrub mutilated by injudicious pruning, or by pruning done at the wrong season, that a timely reminder may not be out of place. It is not often that it requires much attention with knife or secateurs, a thinning out of weak, overcrowded shoots, with the shortening of any that may be encroaching too far on the available space, being all that is necessary. The best time to do this is just now, when the flowers have faded. Young wood that is made during the coming summer is likely to give the best display of flowers next winter.

Spraying Fruit Trees: A Warning Note.—Owing to the very mild winter and the subsequent condition of certain fruit trees, we take this opportunity of warning readers against the use of caustic alkali wash, recommended by Mr. E. Molyneux on page 85, upon those trees that are very forward. A few days ago we observed Apple shoots, of the variety Keswick Codlin in particular, just on the point of breaking into growth. Although February is usually considered a good month for winter spraying with the caustic alkali wash, yet it practised this year it will have an injurious effect upon those trees already commencing growth. It is, however, perfectly safe to use it upon those trees where the buds are still quite dormant.

CORRESPONDENCE.

The Editor is not responsible for the opinions expressed by correspondents.

Rose Florence Haswell Veitch.—I strongly recommend this Rose for the garden; it is vigorous in growth, flowers freely, is fragrant, and the colour is especially noticeable—scarlet, with a flush of velvet overlying the petals.—E. M.

Iris Vartanii and its White Variety.—We were interested to see figured in your February 8 issue, page 69, the fine pan of Iris Vartanii, and should like to call attention to the very little-known white variety of it which goes under the name of Pearl of Jerusalem or White Pearl. We introduced it a few years back as a variety of *Histrio*, but it showed itself to be Vartanii as soon as it flowered. Another point worth mentioning with regard to the species is its delightful fragrance, which Sir Michael Foster seems to have overlooked in his invaluable little book on bulbous Irises. It strongly reminds one of *Almonds*.—R. WALLACE AND CO.

Kerria japonica flore plena.—Mention is often made of the usefulness of this flowering shrub for various purposes, but nothing is said of its value as a wall climber for a northern aspect—a site at all times difficult to effectively clothe with flowering subjects. Covering the whole of the northern side of a cottage here, 18 feet high, this *Kerria* makes a glorious sight every year, smothered quite thickly as it is with its rich orange-coloured blossoms. All the attention it receives is the tying of the current season's shoots to the main branches directly flowering is past.—E. M., *Bishop's Waltham, Herts.*

Sweet Peas Reverting to the Wild Type.—I was interested in reading the article by Mr. Vernon Hill on this subject, page 57, February 1 issue, and rather surprised to find there could be any doubt on the point indicated in the above heading. It is a matter of very common experience in India that Sweet Peas of good varieties in the course of two or three years will have gone back to two types (1) blue and maroon, presumably the purple referred to, and (2) white and pink. Now, in India we have not the wild Sweet Pea, and the reversal is evidently due to the promiscuous hybridisation. The first year a few come true, the second still fewer, and I believe I am right in saying that in the third year you would find none. If this is not the case in England, it would be interesting to know why it occurs in India. I should like to know also whether the white and pink is one of the wild types.—A. NEWNHAM (Lieutenant-Colonel, I.A., retired), *Fabron, Nice.*

A Remarkable Hydrangea.—I am sending a photograph of a very free-flowering *Hydrangea* growing on the premises of the Shanklin Tennis Club. It is said to have been planted in the memorable year of 1887, and, as the picture shows, it has now exceeded its allotted space, having quite grown out of bounds. Last year this shrub carried about six hundred heads of bloom, and was the pride of Mr. W. R. Jones, the club gardener. Its position is 100 feet above sea-level, and the flowers, of which only about half are shown in the photograph, are invariably deep blue.—H. C.

A Proposed Daffodil Society.—A misquoted Latin phrase in the Rev. J. Jacob's article on this subject which appeared on page 75 of our issue for last week, has aroused the poetic spirit of a well-known Daffodil expert, who sends us the following:

"CARTHAGO EST DELINDUM."

A healthy rule, in my days at school,
To block and birch would send 'em
Who wrote, in defiance of godly alliance,
Carthago est delendum.
For, though he'd own that the Punic town
Was a masculine virago,
The Roman said (and note that he made
The words the other way go)
Not "it," but "she destroyed must be,
Delenda est Carthago." G. H. E.

—I was very glad to see Mr. Jacob's interesting article in your last issue on this subject. Following

SIR TREVOR LAWRENCE, BART., K.C.V.O.

as it does the letters of Captain Kitchin and Mr. Carne Ross, both of whom I know to be keen Daffodil enthusiasts, it will, I feel sure, be the means of uniting all lovers of this flower in their determination to give it a national society of its own. In my opinion a National Daffodil Society should have been formed years ago, and now that new varieties of the Daffodil—good, bad and indifferent—are being introduced yearly by the thousand, it appears to me to be imperative that we should have a society whose business would be to sift the good from the bad, draw up new classifications when necessary, and generally take charge of the Daffodil and do what the National Rose Society does for the Rose. If there is any single flower that should have a national society of its own, it is the Daffodil. Probably there is no other hardy flower which exists in such a variety of forms and which offers such possibilities to the hybridist. It is a florist's

flower and a decorative flower, and although it repays good cultivation, is easy to grow. The Royal Horticultural Society and the Midland Daffodil Society hold excellent shows, and I look forward each year with more pleasure to my visit to Birmingham, where one meets one's Daffodil friends. These shows, however, cannot do what a national society could for the Daffodil.—N. Y. LOWER, *Prestegyn, Radnor.*

Carnations and Cats.—Many will consider that the only connection between the two is that the initial letter of each is the same. Such, too, was my opinion until lately, when I found the growing points of many of my Carnations eaten off. My thoughts at once reverted to sparrows, and I immediately decided that those cheeky but not wholly mischievous birds should be fed no more. Although I watched the sparrows for a long time, I could obtain no evidence of their being the authors of the mischief, but found out quite sufficient to show that I was blaming them for damage which they did not do, as I detected the culprit in a neighbouring cat, which was several times seen carrying out its work of destruction. Cats sometimes eat grass for medicinal purposes, and the resemblance between the two is probably the reason why it turned its attention to the Carnations. Afterwards I found it eating both Pinks and Thrift. Lack of grass is not the cause, as there is plenty close by.—H. P.

Serious Losses Among Roses.—Many Rose-growers in the South-West of Scotland will have reason to sympathise with Mr. Blair, whose note appears on page 66 of last week's issue. Climbing Roses here have suffered extensively, and many which have stood unharmed for a number of years have been severely injured. I do not like iron for climbing plants, and all my climbing Roses are either on pillars, walls, or trellises, yet they have suffered greatly, and I fear that one or two, at least, are completely gone. Most of them are severely crippled. This is noteworthy among the wickurianas, and this is not surprising in view of the "Tea blood" in these charming Roses. The typical wickuriana is all right, and some of the hybrids have come through with comparatively little injury. I have been much surprised at one plant of the old Fellenberg grown as a climber, which has been in its present position, sheltered from the north and east and against a wall and arch for some years. This plant is cut to the ground. Another, on a pillar, is not so much injured.

Dorothy Perkins is partly injured, and is worse in some parts of the garden than in others. One peculiar thing with Dorothy Perkins is that a plant in a place where it generally suffers from wind in bad summers is little the worse, and a plant of White Dorothy against the same arch as the one of Fellenberg alluded to before is quite fresh and healthy-looking. Tea Rambler, which is often hurt in winter and is not so satisfactory as one would like, looks sadly crippled and will hardly recover. Blush Rambler is all right. So is Lady Godiva, and only some two or three of the considerable number of other ramblers and wickuriana hybrids are much harmed. Crimson Rambler has suffered considerably. Dwarfs are not much the worse, but these were saved by a heavy snowfall which remained on the ground during the worst of the frost towards the end of November and the beginning of December.—S. ARNOLD, *Dumfries.*

March 1.—Société Française d’Horticulture de Londres Meeting.

ROCK AND WATER GARDEN.

THE FIRM PLANTING OF ALPINE FLOWERS.

NOW that planting-time will soon be here, it seems a good thing to urge upon amateurs and others the necessity of firm planting of alpine flowers. I have seen so many instances of plants being lost through planting them too loosely or in too loose soil that it seems only right to caution beginners, in particular, on this point. One is frequently consulted regarding the losses among alpinists, and it is not too much to say that a large proportion of these are caused by defective planting. This frequently arises through the soil being made unduly light by the addition of too much leaf-soil and sand. Both are good when used rightly but an excess is injurious.

operation. The result was that the alpinists never looked back again, and by the end of the season they were in excellent condition.

The quantity of leaf-soil and sand to be used depends on the quality of the loam; the stiffer the latter is, the more leaf-soil and sand is required. Then the leaf-soil used is often too flaky and improperly matured, so that fungoid growths appear, to the detriment of the alpinists planted in it. I would emphatically enforce the necessity of firm planting, spreading out the roots well, pressing the earth well about them and finishing off by pressing it about the neck of the flowers, and putting a few stones about them also if they are not planted in crevices. “Plant firmly” is a piece of advice which should not be neglected. — AN OLD ALPINIST.

A LITTLE KNOWN CAMPANULA.

It is hardly possible to overpraise the charming *Campanula raddeana*, but it has one defect which it is unwise to endeavour to conceal. This is its

A BLUE-FLOWERED HYDRANGEA GROWING AT SHANKLIN, ISLE OF WIGHT. (See page 78.)

I had a striking instance of this a year or two ago, when, on being asked to visit a garden to advise about alpinists which were not doing well and where many of them were dying off, I found that they were planted in soil containing far too much loose, flaky leaf-mould and sand. This would not have mattered so much even had the compost been made quite firm, but it was laid in the slackest fashion and no attempt had been made to firm it at all. Then the plants had been put in and never pressed into the soil or the latter made firm about them. In consequence, their roots never had a chance of taking hold of the soil, and many of them were on the verge of their demise. At once the hitting of the plants was advised, together with the addition of some good loam and making the whole firm, though not into a stiff mass. Then the alpinists were replanted, with the soil made firm about their roots, and a good watering given, the month being May, not the best time for the

inability to maintain itself upright without some assistance—rather a serious drawback for a plant which is so pretty on rockwork. One does not like to see a plant on the rockery upheld by a stick or twig, yet this seems necessary with *C. raddeana*, unless we can grow it through some slender rock shrub which would uphold its stems. These fall forward owing to the weight of the many large bells which they bear, and, unfortunately, these flowers seem always to fall with their “faces” against the soil, so that they do not show so nicely as do many other flowers with this failing. But *C. raddeana* is such a lovely thing that it is worth while trying to contrive some support which would not be obtrusive. With me it is about a foot high, and gives with great freedom stems laden with purple blue bells on a plant of the freest-growing habit, the roots running sufficiently rapidly to increase quickly without being too troublesome. — S. ARNOTT.

THE FRUIT GARDEN.

THE WINTER SPRAYING OF FRUIT TREES

CONTINUING my article, page 637 of the last volume, I now purpose dealing with some chemical winter washes employed for the double purpose of the cleansing of the trees from moss, and lichen, and from such pests as eggs of the winter moth, woolly aphid, mussel-scale ova, Apple blossom weevil, oyster-shell bark lice, earwigs and the caterpillar of the Codlin moth in its cocoon.

The Board of Agriculture, in the valuable leaflets issued, strongly recommend the use of winter washes for fruit trees, and mention the Woburn Wash as being desirable.

In addition to the pure lime spray noted, I am using the following wash, made from this formula, in addition to some prepared washes which I will also note, as in many instances those persons with but a few trees prefer a prepared wash to the trouble of preparing one from a formula. In the soil here lime is not needed so much as in soils of a different character, as the subsoil is chalk at some distance from the surface. For this reason other washes suit me equally as well as the lime spray. Caustic soda, 1½ lb.; copper sulphate, 1½ lb.; lime, ½ lb.; paraffin emulsion, 5 pints; water, 10 gallons. Dissolve the copper sulphate in six gallons of water and slake the lime in three gallons of water. The dissolved copper sulphate should be run through a fine sieve to remove any portions of a gritty character. Then add the paraffin emulsion and stir them together, adding the caustic soda and sufficient water to make ten gallons.

The paraffin emulsion requires careful preparation. Boil one gallon of skim-milk, gently, gradually add two gallons of paraffin by pouring it gently in the middle of the milk, but not in sufficient quantity to take the milk off the boil. Add 1½ lb. of soft soap, gently whipping it up in the middle of the vessel, keeping it away from the side of the copper, as it is so liable to burn to the vessel.

Some growers may prefer to use iron sulphate in the place of copper sulphate; in that case add half a pound of iron sulphate instead of the 1½ lb. of copper sulphate to the same ingredients and the same quantity of water. Prepare and apply in the same manner any time between November and the end of February.

A simple winter wash can be made with lime and sulphur only in the same manner as recommended in my book, "Chrysanthemums and Their Culture," which I wrote and practised in 1886. Place 2 lb. of sulphur and 2 lb. of lime which has not been slaked in ten quarts of water, and boil for twenty minutes. Use four wineglassfuls of the mixture to four gallons of clean cold water. This is a capital fungicide for summer use also, using it at half strength, for many of the insect and fungus pests which attack the trees.

Of prepared washes the following are desirable: Bentley's Concentrated Alkali Wash is most efficacious in cleansing the trees, rendering the bark quite bright and imparting a dark colour to it. In using this mixture I would caution users not to drench the trees unnecessarily with the liquid, especially standards, because the stems become too saturated with the wash running down, collecting as it does from the branches to the stem, and, of course, the older the tree the more numerous are

the lodgments in the stem for the wash; an undue quantity might do some slight harm. Dissolve the contents of one tin in fifteen gallons of slightly warm soft water.

Messrs. Strawson prepare an article known as Strawsonite, which is efficacious, easy to apply and quite safe. Add 2 lb. Strawsonite to fifteen gallons of cold water. Keep the spray fluid well agitated while spraying to prevent the settling of the mixture at the bottom of the sprayer.

Messrs. Voss and Co. prepare a liquid winter wash which is easy to use, at the rate of one gallon to fifty gallons of water. This wash I am giving an extended trial this season as it is so simple of application.

Swanmore Park.

E. MOLYNEUX.

THE KITCHEN GARDEN.

OUTDOOR TOMATOES.

THE past year was, on the whole, not very suitable for the production of high-class Tomatoes in the open garden. Some very fair fruit, however, was secured from plants growing upon south walls. The seed for this year's supply of plants should be sown in heat during February and March. Failing a warm greenhouse, use may be made of a hot-bed to raise the seedlings. A small pan, or even a pot, will contain sufficient for the average amateur's garden. Fine soil, made moderately firm, and good drainage are essential points in the production of healthy plants.

The plants from their first appearance must be placed in a position where they will obtain the full advantage of light, and as soon as they are strong enough, air within reason should be admitted. This will secure short-jointed, sturdy plants, so important a factor in the ultimate success of the crop. The seedlings may be pricked out when large enough to handle. I prefer to plant them around the edge of 5½-inch pots; it is then a simple matter to divide the ball of soil and pot on the plants when they are ready without injury to their roots. The plants grow quickly as the season advances, and they may be given a final shift singly into 5½-inch pots. As these pots become full of roots and the sun increases in power, plenty of water will be required by the plants. They may be arranged in a frame, allowing plenty of room for the air to circulate freely between them. Frames are so often overcrowded during the spring, and it is a good plan to arrange the Tomatoes on a bed of ashes under the protection of a south wall or fence during the latter part of the month of May. A framework of Bamboo canes or poles may be fitted up, on which mats may be placed at night as an extra protection against damage by frost. The first week of June is a suitable time for planting.

The first places to plant are those against walls or on fences facing the south or west. The next best places are on borders immediately in front of these walls or fences, while in some localities and during favourable seasons good crops have been taken from the open ground. Do not add manure at the time of planting, except in cases where the soil is very light and poor. Plant firmly. Secure the plants to the wall or to stakes. Apply water as required. Remove all side shoots as they appear. A mulch of manure is advantageous in preserving moisture and affording food to the plants. Three, or in sunny positions four, bunches

of fruit may be allowed to set on each plant. The plants should then be stopped at one leaf above the last bunch. A portion of the foliage may be cut away, so that the fruit may derive full advantage of the sun. Do not entirely denude the plants of their foliage. The latest bunches seldom ripen thoroughly outdoors. They may be placed on the shelves of a greenhouse or in a sunny window to finish. Satisfaction and Sunrise are excellent varieties for growing in the open garden. COLIN RUSE.

THE GREENHOUSE.

NOTES ON ORCHIDS: CALANTHES.

THERE are several Orchids well cultivated by gardeners who do not claim to be Orchid-growers in a general sense. Calanthes are among them, for they are special favourites with those who live outside the metropolitan area and away from large manufacturing centres, where dense, smoky fogs play havoc with the blooms, while the absence of light also has a bleaching effect on the flowers.

In an ordinary establishment there usually exists a Melon-pit, a shelf in the vinery, or a Cucumber-house, where Calanthes thrive admirably. At this season they will soon commence to grow, and when the new shoot is about two inches long and ready to push out a batch of roots, the repotting may be taken in hand. The bulbs have, no doubt, been kept quite dry at the base through the winter months, and to prevent any injury to the new growth, the pots should be given a thorough watering a day or so before potting operations begin. The old soil is then shaken out and all the roots cut away excepting a little tuft to hold the bulbs in position till they become established. One bulb behind each growing point is sufficient, and where the older bulb has not decayed, it could be placed in some silver sand till growth is apparent, if it is desirable to increase the stock. However careful the grower may be, a few of the bulbs lose their top; but these may also be utilised in a similar way, when they will generally produce a "break."

Soil and Repotting.—A suitable rooting medium consists of the best fibrous loam one-half, peat one-fourth and partly-decayed Oak leaves one-fourth, and to every bushel of the mixture add a 6-inch potful of crushed crocks or finely-broken charcoal. Ordinary flower-pots prove the best receptacles, which should be filled one-fourth of their depth with drainage, and over this can be arranged a thin layer of fibrous loam. The bulbs ought to be potted singly, the larger ones being placed in 6-inch pots and the smaller ones in 4½-inch and 5-inch pots. Make the compost fairly firm and allow the base of the new growth to rest upon the soil, which may be an inch or so below the rim. This will leave ample space for watering and top-dressing during the summer months. After the repotting is completed, the bulbs should be provided with a light position in a house where an average temperature of 60° to 65° Fahr. can be maintained; but as the sun gains power no harm will accrue if the thermometer rises to 75° or even 80°. Keep the surroundings moist, but scarcely any water will be required at the root for about six weeks. As growth advances and root action becomes more vigorous, the water supply can also be increased, and from this stage till the spikes are removed the plants must never be permitted to suffer

from lack of moisture at the base. As the foliage grows, additional stage room must be given and the plants kept about a foot from the roof glass. Plenty of light is necessary, short of scorching the leaves; but blinds made of thin canvas will be required for a few hours each day when the weather is bright and hot. Ventilation is a most important factor in the successful culture of Calanthes, for they refuse to be healthy in a close, stuffy atmosphere; but air must be admitted cautiously to prevent cold draughts passing over the plants. Spraying overhead is not recommended, but the stages and floor should be damped two or three times each day throughout the growing period. Some growers advocate liquid manure, but personally I do not advise its use. If, however, anyone wishes to experiment with a few examples, it ought not to be applied till the new bulb is formed.

When growth is near completion, the foliage will begin to show signs of decay at the tips, and water will be required in slightly smaller quantities, while the atmosphere may be less moist, and a little more top ventilation will help to consolidate the bulbs. The flower-spikes will now soon appear, and their life will be prolonged if they are arranged in a dry house where the temperature is about 60° Fahr. when fully expanded. Directly the scapes are cut, the bulbs (still left in their pots) may be stored on a dry shelf till the spring. No water is needed, and the temperature ought not to fall below 55° Fahr.

Selection of Varieties.—C. Veitchii is one of the most popular in cultivation, the flowers being a rich rose colour. The varieties of C. vestita, such as luteo-oculata and rubro-oculata, are very pleasing, while for a later-blooming kind C. Regneri should be chosen. C. Harrisii is a beautiful pure white variety, while C. Bryan, C. Bella and C. William Murray are also desirable subjects. SENTINEL.

CINERARIA BEAUTY OF CAMBRIDGE.

THIS attractive and useful greenhouse plant was raised some years ago by Mr. R. I. Lynch, M.A., of the Botanic Gardens, Cambridge, by crossing Cineraria Heritieri with a white form of the ordinary garden Cineraria, and is quite intermediate between the two parents. The light, graceful flowers are white with a violet centre, some of the floret rays being slightly tinged with blue, making it a very desirable plant. It is readily increased by means of cuttings, and if given the same treatment as the ordinary garden Cineraria, good plants can be grown in 5-inch pots, equally as useful for room decoration as for the greenhouse. A plant identical to the above was exhibited some time back under the name of C. hybrida, said to be a cross between C. cruenta and Senecio Tussilaginis. Undoubtedly there must have been some mistake in the names of the parents, for it is quite evident such a cross could not give the same result as C. Heritieri crossed with a white form of the ordinary garden Cineraria, which are certainly the parents of C. Beauty of Cambridge.

As already stated, this is a charming and useful plant, and one that ought to be more widely known. In common with other Cinerarias it should be grown in quite a cool house, and have an abundance of fresh air at all times. Cold-frame treatment is best for the plants during the summer, where they must be shaded from brilliant sunshine. F. G. PRESTON.

THE ROSE GARDEN.

SOME OF THE NEWER HYBRID TEA ROSES.

(Continued from page 72.)

Rayon d'Or (Pernet-Ducher, 1910)—This Rose can fairly be termed unique, raised from Mme. Melame Soupert crossed with Soleil d'Or. It created a great sensation when first exhibited, and its fame spread to England long before we saw flowers of it. When exhibited by Dr. Waddell for M. Pernet-Ducher at the Royal Botanic Show in 1910, when it was awarded the gold medal, it attracted all who saw it by reason of its colouring. Like all Roses that are at all out of the common, its first year found it suffering very much from over-production, and the plants that reached us were surely the smallest that were ever flattered by the name of plant. I was fairly fortunate, but I saw a batch that it would have been difficult to find

It is a great break from the hybridist's point of view, and its colour and robust constitution have no doubt caused it to be freely used as a parent, so that we can reasonably look forward to a Rayon d'Or without thorns, or perhaps I had better say with fewer thorns. It is free-flowering, and the flowers are not injured by rain; a bed of it makes a fine splash of colour when in full flower.

Rose du Barri (B. R. Cant and Sons, 1911).—The name fairly describes the colour of this Rose, which makes a good May bedder. Fully expanded, the flowers remind one of a Shirley Poppy. It is very free-flowering and fragrant, and produces a large number of buds; these should be thinned to three or five, otherwise the flowers will be small. Although a Rose of recent introduction, the raisers are able to offer it at normal prices—I believe 1s. 6d. a plant. One spray makes a very effective ornament in a vase, with its centre flower fully out and surrounded by three or four buds in various stages.

CINERARIA BEAUTY OF CAMBRIDGE, A GARDEN HYBRID THAT IS USEFUL FOR THE GREENHOUSE.

any wood on bigger than an ordinary safety match. The result was that we had to wait another year before any decent flowers or plants could be obtained, and it was only in the summer of 1912 that the Rose made its way into most of our exhibitions. It is a vigorous grower, of fairly branching habit, rather apt to send up one strong shoot that absorbs all the strength of the plant. Excellent foliage, of bright bronze green colour, that seems quite mildew-proof. I saw no sign of mildew on any of my plants last season, when I suppose mildew generally was as bad as it is possible to be, and that is saying a good deal. The great feature of the flower lies in its wonderful colour; it is without question the deepest yellow Rose we have, and the colour lasts; but it is, to my mind, better in the garden than in the house, the colour being a little crude for decoration; and another point that rather detracts from its use as a decorative Rose on the table is that its thorns are terrible.

Rose Queen (The E. G. Hill Company, 1911).—This is a free-flowering garden Rose of American introduction, and no doubt very useful under glass. Mr. Gurney Hill, when over for the "International," told me it was particularly free-flowering; whether it will prove so out of doors with us I cannot say, but that was its characteristic under glass. It is deep pink or full rose in colour, of good habit, but not particularly distinct. A pink Rose has to be particularly good—for example, Miss Cynthia Forde—if it is to take a place in the ranks of pink Roses.

Reine Mere d'Italie (Bernaix, 1911).—My solitary plant of this Rose gave me some excellent flowers last summer. It is a good yellow, of an ochre shade, very free-flowering, of fair size, and generally satisfactory.

Senateur Mascurand (Pernet-Ducher, 1910).—This is a fine Rose, of good shape and substance, but its colour is variable. Personally, I do not

object to a Rose on this ground, but it, of course, would not do to plant it in a bed forming part of a colour-scheme unless it is used to shade from a yellow into a white.

Souvenir de Gustave Prat (Pernet-Ducher, 1910).—A Rose with similar characteristics to the last named, which latter, however, I prefer. The buds of this Rose are possibly a trifle longer, but with me the other Rose was the better grower and certainly more free-flowering. I do not think both are wanted.

Sunburst (Pernet-Ducher, 1912).—A Rose that has caused much controversy. Under glass there can be no two questions, I think, of its beauty; out of doors it behaves, apparently, in some gardens indifferently, in others well. I think position has something to do with the result. It does not like full sun, and in such a position loses its colour very quickly. My plants get no sun till late in the afternoon, and I had some wonderful coloured

inside decoration and garden purposes, is unquestioned if flowers that will hold their deep cadmium yellow colour are produced.

Southampton. HERBERT E. MOLYNEUX.
(To be continued.)

COLOURED PLATE.

PLATE 1465.

TWO NEW SWEET PEAS.

THE two Sweet Peas shown in the accompanying coloured plate have much to commend them to the notice of those particularly interested in these flowers. In these days, when so many so-called novelties so closely resemble older sorts, it is a relief to get new ones that are distinct, which the varieties depicted in the coloured plate certainly are. In Muriel Quick we have one of

THE FLOWER GARDEN.

KNIPHOFIAS, OR TORCH LILIES.

KNIPHOFIAS, or Tritomas, to use an older generic name which still clings to them, are valuable hardy perennials for summer and autumn flowering. Several popular names, such as Flame Flower, Red-hot Poker and Torch Lily, have been fittingly applied to them. No garden of any size can be considered complete without the rich, warm colours of their flowers. The genus *Kniphofia* contains some forty species, chiefly natives of South Africa. Comparatively few of these, however, are grown to any extent in gardens, as for general culture and beauty the species are surpassed by the numerous hybrids and garden varieties raised in this country and on the Continent. Though generally looked upon as hardy plants, in cold districts and exposed positions the precaution of protecting them with coal-ashes, leaves, or Bracken in winter is desirable, for it must be borne in mind that they grow wild in a country warmer than this.

Soil and Situation.—*Kniphofias* will grow in the cultivated soil of most gardens, provided it is well drained. For preference a light sandy, rather than a heavy, loam should be provided. An annual mulching of well-rotted manure in June is beneficial. Propagation may be effected by division of the clumps, preferably during March, or in autumn if more convenient. *Kniphofias* may also be raised from seeds sown under glass during February and March, or outdoors in April. When established and flourishing *Kniphofias* should be left undisturbed, merely pricking over the surface soil between the plants in spring, and keeping the ground at other times free from weeds. The plants delight in abundant supplies of water in summer and autumn. It is often recommended to plant *Kniphofias* by the lakeside. The plants, however, must be located a sufficient distance up the slope of the bank, so that the water does not reach the roots in winter. In such a position few herbaceous plants can be so effectively employed planted in bold groups or masses. Most readers will be aware of the value of *Kniphofias* for

A LARGE BED OF TORCH LILIES. WHEN MASSES IN THIS WAY THESE PLANTS CREATE A DISTINCTIVE NOTE IN THE GARDEN.

flowers in consequence; with me it was quite satisfactory. Here, again, the over-production question comes in, and I think we must wait before passing a verdict. Every eye was propagated from last year and the year before, with the inevitable result. We were told at the "International" of a method of pruning, or, rather, stopping, akin to that which the *Chrysanthemum*-grower practises—the leading shoot not being allowed to flower, but stopped at two eyes, both of which would then produce deep-coloured flowers. Two groups of plants were exhibited, the first after the normal pruning being allowed to flower and showing blooms white edged if not quite white throughout, the second, stopped in the manner suggested, showing deep-coloured flowers. It is vigorous and of Rose carries few thorns, and its beauty, both for good branching habit. Unlike *Rayon d'Or*, this

the beautiful veined Sweet Peas, of which the *grandiflora* or unwaved variety *Helen Pierce* was the forerunner. Ever since it was introduced raisers have been endeavouring to secure it in a waved form, and *Muriel Quick* is the nearest and most pleasing approach to it that we have seen. The other variety, *Mrs. D. Denholm Fraser*, is a very striking Sweet Pea, its large, bold flowers, with their vigorous splashes of bright orange, making a gay picture in the garden and a fine addition to an exhibit in the show tent. It is a counterpart of the beautiful *Mrs. W. J. Unwin*, except in the colour of the flakes, which is, of course, quite distinct. Both *Muriel Quick* and *Mrs. D. Denholm Fraser* were raised by Mr. W. J. Unwin of Histon, Cambs, to whom we are indebted for the flowers from which the coloured plate was prepared.

the herbaceous or mixed borders, and they are also particularly effective for beds in the pleasure-grounds. Even when not in flower the clumps or tufts of broad and long grass-like leaves are ornamental.

A Good Selection.—*K. aloides*, or *Tritoma Uvaria*, is the old Red-hot Poker of the cottage garden. There are several forms worthy of cultivation with flower-spikes 4 feet to 6 feet high, sometimes even taller than this—*glaucescens*, yellow, tipped with orange scarlet; *grandiflora*, scarlet and yellow, a grand variety producing tall, vigorous spikes of flower in autumn; *maxima*, scarlet and orange; *nobilis*, one of the most vigorous and hardy varieties, flowers orange red; and *Saundersii*, a very free-flowering variety with orange scarlet flowers. *K. aloides* is one of the parents of most of the strong-growing hybrids. The following list

Two new Sweet Peas —
Blue: Muriel Quick.
Red Flaked: Mrs. D. Denholm Frazer.

comprises a selection of the best: Chloris, apricot yellow; corallina, coral red; Lachesis, golden yellow; Obelisk, rich yellow; Pfitzeri, yellow and scarlet, a strong grower; R. Wilson Ker, coral red, a vigorous plant; Triumph, orange yellow; John Benary, dark orange red; Rufus, yellow, shaded crimson; and Victor Lemome, coral red.

The Small-flowered Torch Lilies.—As a contrast to the noble and vigorous varieties and hybrids of *K. aloides* we have the miniature or small-flowered Torch Lilies. They require more attention and care than their stronger brethren, or during a severe winter many losses among them will have to be recorded. These miniature *Kniphofias* succeed best in light, sandy soil and warm, sunny positions. They are charming for the front of the herbaceous border, the mixed border, and may also worthily find a place in the rock garden. In some gardens, to guard against loss the plants are carefully lifted and heeled in light, sandy soil in a sheltered spot, protecting, if necessary, still further till spring. The following are the most important miniature species: *K. breviflora*, yellow, producing slender spikes 2 feet to 3 feet high, a rather rare South African species; *K. Macowanii*, soft coral red, spikes 2 feet high, valuable in the rock garden, also from South Africa; *K. Nelsonii*, orange red, a charming free-flowering plant of considerable value grown in pots for the cold greenhouse, a native of the Orange River Colony; *K. pauciflora*, grows about one and a-half feet high, yellow flowers, borne on slender spikes, flowers produced over a long season, a native of Natal; and *K. rufa*, yellow and red, may be truly described as a miniature *K. aloides* in both foliage and flowers, the hardiest and most free in growth of the small-flowered species, free and continuous in flower, a native of the Orange River Colony.

With these species to work upon, hybridists have given us several useful small-flowered hybrids during recent years. One of these, *Goldseis* (citron yellow), has received the award of merit of the Royal Horticultural Society. *Torchlight* is a companion plant, with orange scarlet flowers; *Lemon Queen*, lemon yellow, a distinct plant, with spikes about two feet high; *Solfaterre*, yellow, tipped with green.

In addition to their value in the outdoor garden, the miniature-flowered *Kniphofias* may, if desired,

be very successfully cultivated as pot plants for the cold greenhouse. For cutting, the flower-spikes are for many purposes more valuable than the vigorous kinds, lending themselves more readily to light and graceful arrangements.

THE JAPANESE ANEMONE.

This is beyond doubt one of the most popular garden flowers of to-day. For massing in large beds by the water-side, on the outskirts of the

after which it will need little or no further attention. In the accompanying illustration is seen an effective grouping of the variety *Queen Charlotte* of a soft rosy line, and one of the most pleasing in cultivation.

LILIES: A CAUSERIE.

(Continued from page 71.)

ANOTHER Lily that has, so far, reciprocated my affection is the golden and fragrant *L. monadelphum*, which has annually returned my admiration with *Daffodil* yellow bells and whiffs of blended essence of *Hyacinth* and *Poet's Narcissus*. The scent is strong and heavy, even for a Lily, and is almost too much of a good thing early in the evening, when this Lily seems to concentrate its efforts on advertising its presence, which I take to be a sign that in its own country it lays itself out for the visits of crepuscular insects, probably some large hawk-moths that fly at early dusk, when, of course, pale lemon yellow and strong scent would prove good guides for these hungry visitors, who come only with the idea of sipping honey, but are welcome to the Lily as its best-appointed means for cross-fertilisation. It is said to be one of the best Lilies for permanent planting, hating disturbance and improving in vigour after its third year's tenancy. That is one of the characteristics I most desire in a plant. I should like to fill a garden with plants whose only needs after a good planting are spring and autumn cleanings of the surface of their bed, and for which patience is the best manner.

I have a feeling, which I cannot exactly trace to book-reading or garden observation, that *monadelphum* prefers a cool, loamy soil, so I should always choose a position for it where shade lies for some portion of the day. Once one gets such a conception of the right position for a plant, it is hard to shake it off, and sometimes noticing successful cultivation in the gardens of others under totally different conditions sets one to look out for climatic or geological differences rather than to account for it by questioning the truth of one's preconceived notions. Still, it is a fact that the best gardeners acquire a knowledge of the geography of their own gardens which is often of the greatest service in choosing a suitable home for a new subject, and yet can hardly be explained in words.

AN EFFECTIVE METHOD OF GROUPING THE BEAUTIFUL JAPANESE ANEMONE QUEEN CHARLOTTE.

shrubbery, or in the herbaceous border it has few equals. Moreover, it is grand for cutting, and when grown in large masses the pink and white flowers may be cut in armfuls during the autumn. It is a plant of easy cultivation, and it is just as well to place it both in sunny and shady positions to prolong the flowering season. No garden is complete without this charming Anemone. It may be planted now in deep, rich and well-prepared soil,

So I have a rooted idea that this fine Lily is a fitting companion for herbaceous Pæonies—the same site should suit both. The poor thing has suffered terribly at the hands of its botanical sponsors, and it laments, moans and groans (the best opposites to rejoicing that I can think of at the moment) in the synonyms Loddigesianum, szovitzianum and Ledebourii, and I daresay, like many of the Ermyntudes and Adolphuses, who wish they had been named Jane or Thomas, would prefer to be called by its shortest synonym, colchicum. The plain yellow forms are most to my liking; but they vary so endlessly in the matter of spotting that, unless you can choose your plants when in flower, it is impossible to predict what you may get from lemon yellow to deep chrome, any of which may be plain or speckled.

L. Henry surprised me more than any other Lily I have planted here. I purchased a bulb when it was new and rare, and also expensive. It was a small one, to match my purse, and I was not greatly in love with its weak, bending-over make of stem and the one or two blossoms it gave me during its first three years here. As it bent over so much, it was mostly the recurved portion of the segments that I saw, and in the choice southern border I gave to so rare a novelty they scorched rather badly. Then I thought it was about good enough to grow on the edge of a grouping of Hemerocallis at the corner of a border in a lawn, and a couple of seasons after the move it shot up a 6-foot stem, still with the arching habit, of course, and to keep it clear of the passing mowing-machine it was staked at the height of 4 feet, and when the remaining 2 feet leant over the lawn, bearing over a dozen great flowers and buds at eye-level, I wanted more Henrys for that corner. They came, and in 1911 were a fine sight, taller than ever, about a dozen stems, and all staked for only half their height, so that they bent over naturally with their wealth of blooms. The great heat of that summer induced them to set seed in a most whole-hearted way, and I greedily left too many pods on and, I believe, rather exhausted the plants, so that this season they were not so high or well budded as usual. But the unusual drought of the whole of April and half of May must have some blame for their loss of inches, and I have a promising younger generation of seedlings from the crop to make up for lack of blooms this year, for, sown as soon as gathered, nearly every seed germinated in the spring. This season's autumn manoeuvres necessitated the hitting of this Hemerocallis group, also the Lilies, and I am rather anxious about the result; so herewith I touch wood in saying most likely I have ruined them, it may be for years and it may be for ever.

(To be continued.)

SEASONABLE NOTES ON CARNATIONS.

Carnations in Frames.—Thousands of rooted layers are potted in the late summer and autumn with a view to wintering them in frames, and the system must be commended with the choicest varieties, and more particularly so in districts where the soil is cold and wet. The precaution is always a good one, and never more so than in the winter through which we are now passing. The wet was incessant in many places, and where the drainage was in the slightest degree defective,

TREES AND SHRUBS.

CLEMATIS MONTANA AND ITS VARIETIES.

A QUICK-GROWING climber and a general favourite wherever grown, the type of this species has long been in cultivation, and is known in the South and West of England as a most effective and floriferous plant for training on a balcony, wall, fence, or other suitable position where it can display its wealth of pure white flowers, which are produced in early summer. It delights in a hot, sunny position on the wall of a house, facing due south for preference, as in such a position the growths receive a good ripening and never fail to produce an abundance of flowers. These are produced on the ripened wood of the previous year's growth, so that any pruning which may be necessary should be done immediately after the flowering period is over. The plant is not at all fastidious as to soil, but prefers one which is light and open and containing an abundance of lime.

The advent of a beautiful rose-coloured variety named rubens, which was introduced by Messrs. J. Veitch and Sons through their collector Mr. E. H. Wilson some eight or nine years ago, was hailed with delight by lovers of this hardy climber, and was awarded a first-class certificate on May 23, 1905, by the Royal Horticultural Society. The plant is of exceptional beauty, and has the merit of flowering freely when only a foot or so high; it further has the additional advantage of not requiring a background to show it to advantage as in the case of the white flowers of the type. For this reason it is most suitable for training over an old tree stump or for furnishing an old or dilapidated tree. Another pleasing way in which it may be used to advantage is that depicted in the accompanying illustration. Several stout branches with their laterals left about a foot long are sunk in a small bed and form a rough or irregular pyramid in outline. At the base of these several plants were planted, and the photograph was taken of the result the second season after. A glance at the illustration will show how rapid is the growth in the first few years, and what a really valuable and effective plant this new variety is.

THE POSE-FLOWERED MOUNTAIN CLEMATIS (*C. MONTANA RUBENS*) GROWING OVER RUSTIC POLES.

many roots perished in the cold ground. In a frame the plants are completely under the control of the cultivator, and it is rare to lose more than an odd one or two where reasonable care is exercised in management. It is impossible to admit too much fresh air to the plants; but torrential rains, snows and severe frosts ought to be excluded. The advance should be slow and strong, so that when the time arrives for putting the plants in the garden, the task can be accomplished without the slightest check being given.

The bulk of the flowers are produced in late May and June, and odd flowers continue to develop all the summer; they are from 1½ inches to 2 inches in diameter.

Another new variety from the same source is Wilsonii, with large pure white flowers, sometimes as much as 3 inches in diameter. It has the additional merit of flowering in August, a period when flowering climbers are scarce. Both of these new varieties are excellent and can be recommended with confidence.

C. P. RAFFILL.

GARDENING FOR BEGINNERS.

HOW TO PROPAGATE BEDDING PLANTS IN SPRING.

OWING to a shortage of cuttings in the autumn, to losses during the winter, and other causes, many amateur gardeners find, at the present time, that they will not have enough bedding plants to properly fill their borders in the summer. It is not too late to supplement the stock of plants raised from cuttings inserted last autumn. Indeed, many spring-struck cuttings grow freely and make very nice plants, which come in useful for front lines of beds and small borders.

How to Root Cuttings Quickly.—The wood of all cuttings inserted at this season is much softer than that made usually at the end of the summer. Roots are emitted from soft wood if this is either subjected to a bottom-heat and a fair amount of moisture. The cultivator must, therefore, endeavour to build a hot-bed, or arrange a frame over some hot-water pipes. Of course, the cuttings may be rooted without any bottom-heat, but more time will be necessary, and probably there will be a higher percentage of losses.

The Compost and Cutting Receptacles. It will be advisable to use a lighter compost now than in the autumn, also one that is much richer, as in the case of many kinds of plants they may remain in the cutting pots until planting-out-time comes, though this course is not advisable. Loam and leaf-soil in equal parts, with plenty of sand added and a 7-inch pottol of rotted manure to a bushel of the combined portions, will do very well. The manure should be placed in the bottom of the pots, pans or boxes, and not mixed with the other ingredients. The smaller cuttings should be inserted in large pots or boxes, and the larger cuttings singly in small pots. For example, Lobelia may be put in the former and Zonal Pelargoniums in the latter. The Zonal Pelargoniums will not require any shift until turned out for

CUTTINGS MAY BE TAKEN FROM BEDDING PLANTS IN SPRING WHERE STOCK IS SHORT

bedding purposes, and the rotted manure in the bottom of the pot will prove very beneficial.

How to Improve Autumn-Struck Plants.—Such kinds as Zonal Pelargoniums, Fuchsias and Coleuses often grow very tall by the time spring comes, and "topping" will improve them and at the same time provide quite a number of suitable cuttings for spring propagation. The tops, denuded of all flower-buds, should be put in forthwith. The cut-back plants will branch out and become nice, bushy specimens, satisfactorily filling more space in the flower-beds when put there.

Fig. A.—No. 1 shows an old Lobelia plant which should be cut down as denoted by the dark

cross-line; then more young, flowerless shoots will grow. No. 2 is not a good slip for a cutting, but if cut down it may be used. No. 3 is the right kind to put in, and may be dibbled in boxes or pots as shown at Nos. 4 and 5. The Alternanthera is much used in front lines and in designs in small beds. Old plants quickly run to flower and are useless, but if side shoots are selected as shown at Nos. 6 and 7, a fine stock of young plants will soon be obtained. No. 8 shows a bad shoot for a cutting of a Coleus plant, and No. 9 an ideal cutting.

Fig. B.—No. 1 shows a Zonal Pelargonium grown tall. This kind of plant should be topped as shown at No. 2. No. 3 depicts the top prepared for insertion as a cutting; No. 4, the wrong way to cut off the stem when making the cutting. No. 5 shows how to take cuttings from Fuchsias, and No. 6 a cutting prepared. No. 7 depicts cuttings in boxes; No. 8, cuttings in pots on side shelves; and No. 9, cuttings in pots on high shelves under the roof glass. They will all do well in such positions, also in warm frames. G. G.

THE BRIDAL WREATH.

THE white Francoa (Bridal Wreath) is a well-known greenhouse plant. The light pink species *F. appendiculata*, is not so often met with in gardens. The latter makes an attractive pot plant, and is also suitable for planting outdoors in sheltered, well-drained situations. Now is the time to sow seed of the Francoas. Use clean, well-drained pots and light, sandy soil. Sow the seed thinly, and place the pots in the warm corner of the greenhouse. When the seedlings appear, place the pots in full light. Pot off singly when large enough to handle, and grow on in good sandy loam and leaf-mould. Young plants of *F. appendiculata* may be planted out during the summer. Choose specially-drained sites for the plants in warm corners of the rock garden, or plant at the foot of south walls. The writer has recently seen a strong clump growing on a bank, which is sheltered by overhanging trees. COLIN RUSSELL

BEDDING PELARGONIUMS, OR GERANIUMS, ARE OFTEN BEST WHEN THEIR TOPS ARE REMOVED IN SPRING. THESE TOPS MAY BE USED AS CUTTINGS.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Chrysanthemums.—No class of plant is more useful than these for beds or borders during the early autumn, and the present is a very suitable time for propagation. If a few stock plants were lifted after blooming last autumn and placed in a cold frame, good cuttings should be procurable in plenty, which will root readily in a very slightly-heated frame. They are easily handled if placed in shallow boxes, from which they may be potted off into 3-inch pots when well rooted, and this one shift should suffice, as they may be planted out during April.

Border Carnations.—In many districts these have to be wintered in frames; but, providing the ground has been well prepared for them, there is no reason now why they should not be planted out during fine dry weather. A dressing of new loam and wood-ashes to the beds or borders will greatly facilitate their growth. Firm planting is essential, and a dusting of soot will help to keep off wireworm and slugs.

Dahlias.—Generally speaking, I look upon young plants of Dahlias as being more satisfactory than old ones, provided they are propagated early and are good strong plants when put out. With this object in view a few tubers should be placed in heat, when they will soon throw up cuttings, which should be taken off when from 3 inches to 4 inches high. These root readily in a mixture of leaf-soil and sand. Too high a temperature is not necessary, as it induces a very soft growth, and this is detrimental.

Flower-Beds.—Now that most of the bulbs are appearing above the soil, it is advisable to go over all the beds and loosen the surface either with the fingers or a small hand drag, taking care not to injure the young growths of the bulbs or the roots of the covering plants. Any losses of these latter should be made good at once, so that the beds have a regular appearance when in bloom, and, needless to add, this work is best done when the surface of the soil is comparatively dry.

Plants Under Glass.

Chrysanthemums (Single and Decorative).—The present is probably as good a time as any for the propagation of these, and the same system as advised for outdoor varieties will answer well. When propagating, do not overlook the fact that good late varieties are specially useful, and extra attention should be paid to this batch, as during December and January there is often a shortage of good long-stemmed flowers, which a good batch of late Chrysanthemums will fill up nicely.

Zonal Pelargoniums.—A batch of cuttings put in at this date makes good plants for autumn and winter blooming. They will root readily in any house where there is a little warmth, and for preference they should be inserted singly in 2½-inch pots.

Ivy-Leaved Pelargoniums.—Though not used as much now for cut flowers during the winter as formerly, they nevertheless are most useful, especially where there is much table decoration, the variety *Minc*, *Crousse* being very pretty for this purpose. Propagate now and stop a few times during the summer, and good bushy plants will be the result.

Dielytra spectabilis, if introduced into a little heat about this date, will throw up strongly, the somewhat glaucous foliage and pendulous spikes of flower making it a first-rate plant for house or conservatory decoration.

Perpetual-Flowering Carnations.—Pot off the young plants into 3-inch pots as soon as nicely rooted, giving them a position near the glass with a temperature of about 50°. Flowering plants, now the days are getting longer, should be given a slight top-dressing of soil and bone-meal, this latter being recognised as one of the best manures for Carnations.

Fruits Under Glass.

Melons.—These should be planted out as soon as fit in a house where there is a good command of heat, 65° to 70° at night being a suitable temperature. Where pipes run under the bed, there will be no need to use manure for bottom-heat; but, failing pipes, the manure is very useful to give

the early plants a good start. A slate should be placed beneath each plant to prevent the roots going directly down into the manure, or too rank a growth will result. Small heaps of soil are the best to plant in, and these may be added to whenever necessary or as the roots show thickly on the surface. Further sowings should be made for succession.

Cucumbers.—These also should be planted, using somewhat lighter and richer soil for the purpose than for Melons. Keep the houses of both the above well damped down and the foliage sprayed over on all bright days; but during cold weather a certain amount of discretion must be used, as a drop in the temperature at night and too much moisture may result in the appearance of mildew.

Tomatoes.—Young plants should be potted on as they require it, autumn sown or struck plants being probably large enough for their fruiting pots, which should not be too large if very early crops are desired. Seedling plants should be kept near the glass, with a temperature of 55° to 60°, making further sowings as necessary to keep up the supply.

Strawberries.—Early batches are now pushing out their trusses of bloom, and these as they expand must be carefully fertilised with rabbits' tails to ensure a good set. If the blooms are not already expanding, it might be advisable to fumigate the plants to keep down fly, and, as syringings should not be so frequent while they are in bloom, a spraying under and over the foliage with sulphur and soft soap will help to keep spider in abeyance.

The Kitchen Garden.

Onions.—On light soils the main crop of Onions should be got in, selecting the varieties that are noted for good keeping qualities, though by sowing early some of the large-bulbed varieties will mature quite well. On heavy soils it might be advisable to delay sowing a little longer, but, providing the weather is dry and the soil in a good workable condition, there is no reason to delay sowing beyond the end of the month.

Parsnips also may be sown now, the same conditions applying as above. In each instance the ground should be thoroughly well worked and a good dressing of soot applied previous to sowing.

Hardy Fruits.

Currants (Red and White).—In last week's calendar I spoke of pruning Gooseberries and dusting with lime to keep off birds. This applies equally well to Red and White Currants, and I have certainly found it more effective than stretching cotton over the bushes, and it is quicker to put on. There is no need to stint the quantity of lime, as a little falling on the soil will prove very beneficial to the bushes.

THOMAS STEVENSON,

(Head-gardener to E. Mocatta, Esq.)
Woburn Place Gardens, Addlestone, Surrey

FOR NORTHERN GARDENS.

The Flower Garden.

Herbaceous Plants.—If the weather is open and the ground in suitable condition, any planting to be done may be proceeded with. Clumps that have grown too large may be reduced, some good, fresh soil worked in where the plants grew and small pieces taken from the outside of the clump planted. The bed or border should also receive a top-dressing of old hot-bed manure or other light, rich material.

Dahlias.—Whenever cuttings 3 inches in length are available, they should be taken and inserted in 2½-inch pots, filled with sandy soil, and then plunged in a brisk bottom-heat. If the cuttings are kept sufficiently moist, they do not require to be placed in a propagating-case.

The Rose Garden.

Trellises.—Wire trellises are objected to on two grounds—first, on account of the wire chilling the shoots during frosty weather; and, secondly, and perhaps with greater cause, on account of the wires injuring the shoots by friction. Here we have overcome these objections by covering the wires on the side on which the plants are trained with split 6-foot lengths of Bamboo stakes. The pith is taken out of the Bamboos when they fit

nely on to the wires, to which they are tied with light copper wire. The light lattice-work extension screens are very artistic and easy of manipulation, but they do not last long.

Plants Under Glass.

Caladiums.—These Aroids are highly decorative either in the stove or in rooms. A portion of the stock may now be started for early work. Place them in a temperature of about 65° and spray twice a day. When fairly started they should be turned out of their pots, the ball reduced, and then potted up into pots two sizes less than those they occupied before, to be potted on in due course. Loam, peat and old hot-bed manure, with a dash each of sand and pounded charcoal, suits them.

Edging Plants.—A good stock of these should be got ready, both for the conservatory and room decoration. Suitable subjects include *Fuchsia Golden Fleece*, *Asparagus Sprengeri*, variegated *Water Ivy*, the variegated form of *Vinca major*, *Lonicera aurea reticulata*, *Tradescantias* in variety, *Fuchsia procumbens* and *Origanum sipyleum*.

Calceolarias.—These should now mostly be ready for their final shift, and 7-inch pots are generally used for this shift. They delight in a light, rich, porous soil, and should not be potted too firmly. A cool pit is the best position for them. Beware of green fly, their only enemy.

Chrysanthemums.—Continue to pot off cuttings as soon as they are well rooted. A slight spray in the early afternoon on sunny days will prevent flagging. More care will have to be taken in watering these, as evaporation is now more rapid and plants in small pots suffer quickly unless closely attended to.

Cannas.—Many of these have very handsome flowers in shades furnished by few other plants. A batch may now be started, and a vinery at work is a suitable position for them. Spray them daily along with the Vines, and when they have pushed a little the rootstocks should be divided up with the aid of a stout pointed stick and a pruning-knife. Put them in small pots and pot on as necessary.

Fruits Under Glass.

Stopping Vines.—The stopping of Vines is an important operation, and should receive timely attention. It consists, first, in stopping the leading growth of the shoot, and, secondly, stopping the laterals and sub-laterals. The leading shoot is usually stopped at one joint beyond the embryo bunch, but it is unwise to draw a hard-and-fast line. All laterals should be stopped beyond the first joint.

Melons.—Where these are ready for planting, the soil should be placed on the bed a day beforehand. The bed should first be covered with turves grass side downwards. The compost should consist chiefly of good sound loam not broken up too finely. About a sixth part of old Mushroom-bed-manure and a little bone-meal and lime rubbish will make an excellent compost. The plants should be put on little mounds as a preventive of canker. Tie to a stake at once.

The Hardy Fruit Garden.

Trees in Grass.—It has been clearly proved that orchard trees in grass do not yield their best when the grass is allowed to grow up to the stem of the tree. Where such is the case, it is therefore advisable to scarify the ground for a distance of 3 feet from the stem and fork it lightly over, working in a little lime and well-rotted manure.

The Vegetable Garden.

Onions.—If the weather is mild at this season of the year, autumn-sown Onions begin to push, and they will be greatly benefited by a light dressing of nitrate of soda, fowl-manure or soot. The ground should also be stirred with the Dutch hoe. It seems early to sow yet, but if one is going in for spring sowing in the open and one wishes to do on's best to escape the ravages of the Onion fly, do not delay sowing a day after the ground is in working order.

Spinach.—It is the early and late sowings of Spinach which pay. As soon as the ground is in order on a south border, make a sowing. It will do nicely between the lines of the early Peas. I am partial to Round Victoria.

Broccoli.—Go over the plants and remove all decayed leaves, and if the ground is in a fit state, hoe between the rows.

CHARLES COMFORT,
Broomfield Gardens, Davidson's Mains, Midlothian.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATE.

Polypodium irioides pendulum grandiceps.

A distinct and striking Fern of dark olive green colouring from Queensland. As shown, the plant was low-growing—less than a foot high and about the same through—the fronds many times branched and somewhat tasselled at their extremities. From Messrs. H. B. May and Sons, Edmonton.

AWARD OF MERIT.

Crocus chrysanthus E. A. Bowles.

A most beautiful and refined variety, and certainly one of the most desirable we have seen. To the predominant yellow shade of the inner surfaces of the petals there would appear to have been added a small proportion of pale orange buff, the mingling of the twain giving the variety an air of distinction. Externally the flowers are lined or feathered with dark purple. It is obviously a free and profuse bloomer. Exhibited by Messrs. Barr and Sons, Covent Garden, W.C.

NEW ORCHIDS.

There is no lack of novelties in the Orchid world, and some extremely interesting and beautiful forms were shown. Two first-class certificates were granted, viz., to *Odontoglossum ardentissimum* Ebor, shown by Baron Bruno Schröder, Englefeld Green; and *Cymbidium Lady Colman Golden Queen*, shown by Sir Jeremiah Colman, Bart., Gatton Park.

Awards of merit were made to each of the following: *Oncidioda Cooksonie*, from Messrs. Charlesworth and Co., Hayward's Heath; *Odontoglossum armandum*, shown by C. J. Phillips, Esq., Sevenoaks; and *Cymbidium J. Davis*, sent by J. Gurney Fowler, Esq., South Woodford.

The foregoing novelties were shown before the Royal Horticultural Society at the fortnightly meeting held on February 4.

CULTURAL HINTS ON NEW AND RARE PLANTS.

TREES AND SHRUBS.

(Continued from page 23.)

Spiræa Henryi.—Several new Spiræas have been introduced from China during the last few years, this white-flowered species being one of the best. In rich, loamy soil it develops quickly and attains a height of 5 feet or 6 feet. No pruning other than an occasional thinning of the branches is required, while it is easily increased by means of cuttings in summer. It is a good plant for a specimen bed or for a group.

Populus lasiocarpa, from China, is a remarkable Poplar, for its leaves are sometimes 1 foot wide, and it has the advantage of red leaf-stalks and midribs. Like most other Poplars, it succeeds best in moist ground, such as is found about the borders of a lake or stream, where the trunk stands clear of the water, but where the roots can take advantage of the generous supply. Cuttings of ripened wood may be rooted during winter.

Rhododendron kamtchaticum, a dwarf-growing plant from Northern Asia, should be given a position where the ground is perpetually moist. Planted on the margin of a bog, in peat and sphagnum, it forms a dense mass 1 inch or 2 inches high. Its habit of spreading by means of underground shoots makes it possible to effect propagation by division of the clumps. Otherwise it may be raised from seeds in the ordinary way.

Pterocarya Paliurus: an interesting new tree from China which may be grown in moist, loamy soil of moderate depth. Its nearest well-known relative is the Caucasian *P. caucasia*, which is known by its long, pinnate leaves and racemes of winged nuts. The leaves of the new tree are equally ornamental, while the nuts are surrounded by wide, circular wings. Propagation is from seeds or by grating upon the common species.

Plagianthus Lyallii.—Although this New Zealand shrub was introduced many years ago, it is not generally grown on account of its requirements being imperfectly understood. By planting it in a sunny position, in light, well-drained, loamy soil, it may be expected to grow well and produce its pretty white flowers freely. Cuttings inserted indoors in sandy soil may be rooted, but propagation is more easily accomplished by layering the branches in spring.

Fothergilla major is a North American shrub which is valuable on account of its white flowers in June and its golden foliage in autumn. It thrives in moist, peaty soil, and is most successful when planted in a mass. Cuttings of side shoots taken in July and inserted in sandy peat may be rooted in a close, slightly-warmed frame.

Rhus Henryii may be grown towards the back of a shrubbery, or as a specimen plant on a lawn, providing it is furnished with good loamy soil. It is a strong-growing Chinese bush or small tree, and the leaves colour well in autumn. No pruning is necessary.

Liriodendron chinensis is the Chinese counterpart of the North American Tulip Tree. Of vigorous constitution, it grows rapidly in good loamy soil, and there is every reason to suppose that it will attain the same height in this country as its American relative, namely, 80 feet to 100 feet. It appears to thrive quite well when grafted upon *L. tulipifera*.

(To be continued.)

ROSES IN A KENTISH GARDEN.

POSSIBLY the following notes about Roses in a Kentish garden may interest such of your readers as—like the writer—are amateurs. Our so-called summer of last year was harmful to most, if not all, gardens.

With me it certainly was an especially bad one so far as my Roses were concerned, for, in addition to unseasonable weather, I was compelled to be absent from my garden from March till June, just the very time when Roses need constant attention. The sorry appearance of their foliage and, indeed, of most of the flowers in autumn was, I fully realise, the unmistakable language in which they reproached me for my neglect. Still, in spite of that neglect, and in spite of unfavourable weather, I have derived much enjoyment from my Roses.

Betty has never done really well with me, but I love her long pointed buds and the delicious fragrance of her full-blown bloom. She seems to whine at being expected to flourish in this part of Kent, but before ousting her I mean to try her in another site, as she is said to bloom right up to Christmas.

Black Prince, though not to be found in the National Rose Society's catalogue, is a good dark crimson Rose that I have known elsewhere to

give lovely bloom. He does not seem happy in his lodgings here, and though he has given me some good flowers, he has not done so as frequently as I expected.

Boadicea yields a sweet bloom, but is so very shy. She never will look you full in the face, and a drooping head is, in my opinion, a fatal fault in a Rose.

Camoens is very sweet, very free-flowering, and indeed, in all respects a very satisfactory Rose with me.

Captain Christy and Captain Hayward both do fairly well with me, but they are not up to the description given of them in catalogues. This may, perhaps, be accounted for by the fact that I bought my plants of both at an auction, a supposition strongly supported by the fact that I have had some good blooms from some half-standards of Captain Hayward I only planted from Messrs. Ben Cant's nurseries last year.

Celine Forestier.—I advert to this Rose, albeit a climber, because for five years I have been trying hard to get her to flourish on a corner post in my verandah, under almost hopeless conditions, being west, getting but little sun and a lot of moisture. She resented being placed in such a gloomy corner, and refused to give me any bloom from the long, lanky, almost leafless stem which more or less entwined itself along the iron arch to its left. However, constant care—I might almost say devotion—has at length softened her resentful spirit, and last autumn I was rejoiced to find a fine healthy offshoot springing up from the junction with the stock, giving promise of better things to come. I hate to be defeated, even by a Rose; that is, I hate being unable to get a Rose to thrive where I particularly want one to grow, and really, for an amateur, I have been wonderfully successful, for I have made Roses grow and bloom where I have been assured by a real rosarian friend it was quite hopeless to expect them to grow. Some time ago I remember showing this expert friend of mine a Marie Bret and a Carmine Pillau in good bloom where he had said they would never thrive. He pointed to his walking-stick and said, "Well, I believe you would make this stick grow if you tried." But I must not boast, for I am sadly aware of the fact that I have had some failures. Is it not the best General who has the fewest?

Possibly my success at times is due to the facts that I am an amateur and an ignorant but determined old man. Still, I am morally convinced, from my limited experience, that determination, coupled with agreeable nourishment and constant loving care, will work wonders with Roses, as with children. For Roses are like children. Let them but feel that you really love them and want them to please you, and I firmly believe that nine times out of ten they will succumb to your affection and do their best to reward your love and care of them. In daring to write thus I know I am opposing one of our greatest rosarians, whose intense love of the Queen of all Flowers induced him to censure so pungently those who "have sent Her Majesty by lobbies and back stairs into dismal chambers." But I write not to rosarians, but to amateurs, and, with all due detestation, I still maintain we are at times compelled to make the best of our circumstances and conditions, and to call upon our children to yield us loving compliance in our endeavour to do so. Since writing the above I have derived much comfort from a perusal of Mr. Walter C. Clark's interesting "Experiences of Growing Roses Under Pines" in the National Rose Society's Annual for last year.

Charles Lefebvre. This popular favourite is as kind to me as I try to be to him. And, oh! what a soft velvety crimson, sweet-smelling flower he gives me!

Chateau de Clos Vougeot.—In 1911 this Rose gave me some truly magnificent blooms, soft and velvety, and of the deepest red I have seen in any Rose. It continued to bloom almost without a break throughout the summer, giving me the first flower on June 1, and I find by my note-book it was still in bloom on November 9. It is a very sweet Rose.

Claudius.—I had my first bloom from this new Rose on June 15 in 1911, and a deliciously sweet one it was. On July 11 I recorded another thus, "A real gem and so sweet." I had a few fairly good blooms in 1912, but not with the erect head of the previous year, due, doubtless, to the heavy rains.

Commandant Felix Faure does well with me, holds his head well up and is very sweet. I got my plants from Messrs. Cocker and Sons of Aberdeen. I am rather inclined to think it is not a bad plan to procure one's Roses from a colder climate than that of one's own garden, and experience rather supports the idea.

Comtesse du Cayla.—I fell in love with this Rose from the gorgeous colour of one worn by a young lady in a railway carriage, and procured it on the recommendation of the young lady's father, to whom I was forced to introduce myself. It is indeed a Rose of beautiful colouring, but is better in a lady's dress than in a garden, as it droops its head despairingly. However, she is a continuous bloomer.

Corallina.—A Rose that smells sweetly and is superb in the bud stage. A good bloomer in autumn and does well with me. The colour is very attractive.

Countess of Annesley.—A deliciously sweet Rose, but has not done well where I planted her, so I played "post office" with her and several other Roses last autumn.

Countess of Caledon, Countess of Oxford, David Harum and Dean Hole.—None of these Roses have done as well with me as I expected, and, as they are sulkier than ever, I shall do with them as with my Countess of Annesley.

Dr. Andry and Dr. Grill.—Both sweet, good Roses and very satisfactory in my garden. Hardy and free-flowering.

Edward Mawley.—I hardly like to say what I feel about this great-bloomed Rose. I paid half-a-guinea for one plant in a pot, and, as far as my experience goes, I would gladly exchange it for any sweet-smelling Rose that grows.

Enchantress.—Even during the neglected and most unfavourable season of last year, I have had quite a profusion of bloom from this creamy white Tea.

Eugenie Lamesch.—A charming little dwarf Rose that thrives splendidly with me and gives me constant clusters of orange yellow blooms, which are always very acceptable.

Fisher Holmes.—A well-known, good Rose that has done splendidly with me. I have two on my espalier that have been a constant delight to me and my friends as we walk along it, as it is good to look at very sweet, and lasts well when plucked.

G. C. Waud.—Described in the National Rose Society's catalogue as "a vigorous dwarf Rose of most distinct shade of colour." Has done, so far, fairly well with me. Its perfume is deliciously sweet, and it promises to be all that one wants.

G. Nabonnand.—A wholly satisfactory Rose with me, except that he is inclined to hang his head a bit. Gave me his first bloom in June, and bloomed well again in autumn.

General Jacqueminot is very sweet, and his large velvety bloom is very grateful to the eye.

General Schablikine.—I had this Rose sent to me from P. Nabonnand with a great flourish of trumpets, but in my opinion he is "not in it" with his rival General, and if his tactics do not improve he shall certainly "be called upon to retire."

G. B. W.

(To be continued.)

BOOKS.

Herbals.*—At the present moment there is in a bookshop in Liverpool an "immaculate" copy, as the dealers express it, of one of the most beautiful herbals in existence, viz., the "De Historia Stirpium" of Leonhard Fuchs, published in 1542. I have paid that shop more than one visit, just to have the pleasure of turning over its pages, for, as Mrs. Arber says, the zenith of book illustration in the herbal is perhaps reached in this exquisite volume. How I should like to one day carry it home! Alas! its price is prohibitive. I would have to produce from £35 to £38 to be able to do so. All old gardening works have appreciated very much in value of late years, and few nowadays can afford to possess themselves of the gems. However, as wise people know that half a loaf is better than no bread, so on the same principle they will find "Herbals" is better than *no* Fuchs, *no* Brunfels and *no* Crispian van de Passe. It is full of excellent reproductions of some of the most characteristic illustrations in these and other herbals of the years between 1470 and 1670, which is the period covered by Mrs. Arber in her book. I have carefully compared a certain number with the originals and, taking these as samples, I can truly say that they are most faithful reproductions, and that the authoress has been very fortunate in her photographer, Mr. W. Tans of Cambridge. There are no fewer than twenty-one whole-page plates and 113 "figures in the text." If one wants to turn to all the examples of one author, they are a little troublesome to find; and I would suggest the insertion of an index of authors' names, with the plants illustrated following on under each one. This would be a great convenience. The letterpress professes to deal with the "origin and evolution" (see the title-page) of the herbal. With all respect to the learned lady who has given us this interesting work, I cannot help feeling that the title is somewhat misleading. When I opened the book for the first time, I imagined I would find "all about" herbals in its pages. I always thought that there were *three* principal factors in the genesis and development of the herbal—medicine, botany and horticulture. As Mrs. Arber practically passes the first and the last of these by and concentrates herself upon the second, I think this should have been indicated, and that a title such as "Herbals in Their Relation to Botanical Science" would have been more appropriate. The whole is written from a botanist's point of view, and not a herbalist's; so much so, indeed, that the authoress gets almost angry because Dioscorides' classification is not up-to-date and certain other people's illustrations are not modernly botanical. (*Quere*: Would she expect to find in Pliny a disquisition on the "motor"?)

* "Herbals," by Agnes Arber, price 6s. Published by the University Press, Cambridge.

If such a change were made, everyone would know what to expect when they purchased the book, and the interest in its contents would be just as great. In a small space much valuable information is given. The happenings of the high-water-mark era of the herbal are unfolded by a well-known botanist, and, what is so nice, they are so related as to be quite understandable by that celebrated personage, "the man-in-the-street." One or two comments on its contents I should like to make. I am a little surprised to read that the fable of the Goose Tree was rejected in the later editions of Gerard. As I read Johnson I hardly think it was. Again, as a friend who dabbles in bibliography points out, Choulant's "Graphische Incunabeln fuer Naturgeschichte und Medicin, 1858," ought to be in her second appendix. It is a bibliography and history rich in its descriptions of Latin herbals. And in the first, since Bartholomaeus Anglicus finds a place, ought not P. de Crescenzi and Vincent de Beauvais also to be mentioned? Lastly, a full list with dates of the various editions of all the works included in Appendix I. would add much to its value, especially if in two or three cases the more accurate word "reprint" were used instead of "another edition," as, for example, in referring to the 1904 Parkinson. These little flies do not in the least spoil the flavour of the ointment. "Herbals" is a book to buy, to read and to keep. It is a *multum in parvo* of many of the most famous herbals of a most interesting period of their history.

JOSEPH JACOB.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—*The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

INJURY TO ANTIRRHINUMS (*H. F. P.*).—We had neither insect nor fungus on the Antirrhinums. We suspect the cause of the death of the shoots is rather frost than a boring insect, and the wet and changeable weather is probably largely responsible for the spotting of the foliage.

WINTER-FLOWERING STOCKS (*M. C.*).—Neither fungus nor insect is to blame for the condition of your Stocks. They are suffering as the result of some cultural error. Perhaps the air has been too dry, or they have become either dry or too wet at the roots, which has shown itself in the dying of the leaf-tops, &c., especially as the plants have apparently been kept in a rather high atmosphere and the leaves have become thin and easily damaged.

DWARF PLANTS FOR FLAGSTONE PATH (*R. H. K.*).—Some of the dwarfest of plants suited to the purpose are: **Erinus alpinus*, **E. a. albus*, *Mentha Requienii*, *Artemisia balcanica*, *Campandula pulla*, *C. pusilla*, *C. p. alba*, *Sedum hispanicum*, *S. h. var. glaucum*, *S. Lydium*, **Dianthus squarrosus*, **D. caesia*, **Linaria pilosa*, **L. hepatica*, *Thymus lanuginosus*, *F. serpyllium coccineus* (quite a gem), **Draba aizoides*, *Veronica repens* and *Hutchinsia alpina*. In certain circumstances the *Aubretias* are valuable, in others they occupy too much space. The whole of the above are perennials. Those marked with an asterisk may be grown from seed if so desired. The better way, usually, is to introduce them by little pieces of plants, first taking out the interstices between the stones to a depth of 2 inches and charging them with good soil.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Office: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

A Good Valerian.—The genus *Centranthus* contains several species of ornamental herbaceous plants, excellent for borders where ordinary garden soil exists. *C. coccineus* grows about two feet high, is crimson in colour, and very effective in a mass or clumps at the back or middle of the border. The flowering period is from June to September, and plants can be purchased for a small sum.

Mulching Pæonies.—Between now and the end of March—the earlier the better in forward seasons—is a good time to apply a nourishing mulch to Pæonies. These plants are heavy feeders, and heavy drinkers, too, by the way, so there cannot be anything more beneficial than well-decayed manure placed around each plant, but not in or actually touching the crowns. Where cow-manure can be obtained, this should be given the preference, particularly if the soil be of a light nature. It is richer than ordinary stable manure, and experience has shown recognised growers that its use better suits the needs of Pæonies.

Our Special Spring Number.—Our next issue will be considerably enlarged, and will contain a number of interesting and useful articles on spring gardening. Seed-sowing, for both greenhouse and outdoor flowers, the best bulbous flowers that should be planted in spring, concise cultural details for the best fifty alpine plants for a small rock garden, and the first of a new series of articles on the Heath garden will be special features. Practical articles on Peas, Potatoes and Tomatoes will also be included. In addition to numerous black-and-white illustrations, there will be a coloured supplement of *Antirrhinums*. The price of this special issue will, as usual, be one penny.

Begonia manicata.—A fine group of this handsome Mexican Begonia, to be seen in the greenhouse at Kew, directs attention to its virtues for conservatory decoration during the early months of the year. As seen at Kew, individual plants, including the inflorescences, are as much as 3½ feet high; the base a group of large ornamental leaves, and the upper part fine, graceful inflorescences of pinkish flowers. In addition to the type, there are varieties with golden-variegated and fringed leaves. It is one of the easiest of the shrubby, or rather the rhizomatous, Begonias to cultivate, for it may be easily propagated from the offsets which appear from the semi-creeping stems, and it grows well in pots or pans in a well-drained compost made up of peat, loam, leaf-mould and sand.

A Beautiful Greenhouse Climber.—It is seldom that *Hardenbergia comptoniana*, a hard-wooded Australian climber, is seen in good condition; not that it is very difficult to grow, but because it is not well known, although a very old garden plant. Its proper place is the cool green-

house, for in such a structure it is safe from thrips and red spider, which prove its worst enemies in warmer houses. In the Temperate House at Kew two plants were noticed recently in full flower, and few more beautiful sights can be imagined than these two large plants perfectly covered with racemes of charming, deep blue or violet, Pea-shaped flowers. This climber proves most satisfactory when planted out in a compost of sandy peat and loam. It must be carefully watered, for it soon suffers if allowed to become dry.

Big Bud in Black Currants.—This pest is likely to be migrating from one bush to another earlier than usual this season, and for that reason we give particulars of a remedy that Messrs. Pearson and Sons of Lowdham, Notts, first made public, and which we have since proved to be good. Use 2oz. of best quality soft soap and 4oz. of Quassia chips to one gallon of water (soft for preference). Steep the chips in cold water for some hours; then bring the water to boiling point and allow it to simmer for twenty minutes. Dissolve the soft soap in a separate vessel and add to the Quassia liquor while warm. Spray with this mixture as soon as the Currant leaves unfold, and repeat it at intervals of ten to fourteen days until the end of May.

A Sweet-Scented Annual.—Now that seed orders are being made out and sent to the seedsman, we would draw attention to the little Night-scented Stock, *Mathiola bicornis*. This is not grown nearly so extensively as it ought to be. It is true that during the daytime the plants have nothing to commend them, but in the early evening the naked-looking stems are transformed into flowering wands. But the fragrance is the feature. There are few greater joys in gardening than to sit by an open window on a summer evening and inhale the fragrance of this little Stock. We always sow it close to the dwelling-house, where a modicum of lime in the shape of mortar from the walls is present. The early part of April is the time to sow the seed, but order it now.

An Easily-Grown Bulbous Plant.—*Volthemia viridifolia* is an excellent subject for the conservatory during the early months of the year, for it may be had in flower from December until March if a little attention is paid to the period at which it is started into growth, while it is equally effective either used alone or mixed with plants having white flowers. A native of South Africa, it is recognised by its long, vivid green leaves, which are up to 18 inches long and 2½ inches wide, and by its rose or pinkish, cream-spotted flowers, which are borne in dense spikes. At potting-time the large, Onion-shaped bulbs are placed on the surface of the soil, or but slightly covered, and a compost of loamy soil, into which a little leaf-mould and sand has been mixed, usually suffices to produce excellent plants.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Laurustinus lucidum.—This, referred to by your correspondent "J. A. D." on page 67, February 8 issue, is largely planted in the Isle of Wight, where it does well, flowering in May. Besides the flowers being double the size of the common variety, they are of a pure white. It can be obtained, I believe, from Messrs. Gauntlett of Chiddingfold under the name of *Viburnum Tinus lucidum*.—C. G. O. B.

A Good Torch Lily.—On page 82 of THE GARDEN of February 15, in the notice of *Tritomas* (*Khiphomas*) I miss the very best of the dwarf varieties, *Marie Derken*. This makes a sturdy plant 1½ feet high, flowers very freely, and is much hardier and less affected by winter damp than any others. The colour of the spikes is brilliant—a gem, in fact; and every collection should embrace the noble, deep golden-flowered *Star of Baden-Baden*, which attains to 5 feet.—GEORGE BUNYARD, *Maidstone*.

"Carthago est delendum."—I apologise for my stupid blunder on page 75, issue February 8. I have, however, this consolation—that without it we would not have had "G. H. E.'s" interesting little bit of poetry on page 78 of last week's issue. I rejoice to find that while he so justly and so tenderly finds fault with the letter, no blame is attached to the spirit of the quotation. *Delenda est Carthago*—a National Daffodil Society must be formed. It is the persistency of the Roman orator that I feel I must copy, if that which I so much desire is to be a *fait accompli*.—J. JACOB.

Rose Rosabelle.—Among the newer climbing Roses I strongly recommend *Rosabelle* (Braubant, at Pottiers), which received a first-class certificate from the National Horticultural Society of France. It is a beautiful and mildew-proof Rose, with glossy and almost persistent foliage, purple-bronzed in youth, and it has a vigorous habit. The elegant, fragrant flowers are of a lovely pink colour, with salmon-like shades, and the reverse of the petals of a fine China pink hue. The flowers are rather drooping, but this must be imputed to the rambling and weeping character of the species. I have a plant in my Rose garden which gave me entire satisfaction and pleasure the first year it was planted, and I intend to plant a second as a very high weeping standard. It will perhaps interest English readers if I tell them that *Anemone Hepatica triloba* flowered this year on January 10 in my garden near Fribourg. I was then in Paris, and my boys sent me a few of these lovely little flowers in their letters.—BARONNE A. DE GRAFFURIED-VILLARS, *Château de La Poya, Fribourg, Switzerland*.

Serious Losses Among Roses.—I am tempted to respond to Mr. Blair's invitation in THE GARDEN of February 8, page 66, as I seldom see my district represented in your excellent paper. We had a snow-storm on November 28, while Roses were in full leaf and flowering freely. Two days later the temperature fell to zero, and the following night it rose to 4° Fahr. Among climbing Roses *Crimson Rambler* suffered most severely, one plant being killed outright. *Rêve d'Or* was also seriously damaged, but it may yet recover. Other Roses show more or less damage. The only standards killed are those of *Jennie Dickson* budded on Briar. Among dwarf Roses *Mme. Jules Grolez* and

Laurette Messimy have been the most injured. *Grüss an Teplitz*, within a few feet of *Crimson Rambler*, shows no sign of injury, and *Blair No. 2*, close to *Mme. Jules Grolez*, is still bearing last summer's foliage quite fresh and green. None of my newly-planted Roses suffered. Generally speaking, those Roses most prone to mildew suffered, and among standards those on the rugosa stock did better than those on the Briar.—M. H. SCOTT-NICHOLSON, *Barn Close, Carlisle*.

A National Daffodil Society.—The majority of Daffodil-lancers will heartily agree with the suggestion put forward by the Rev. J. Jacob and others, "that the time has come when steps should be taken to see if a National Daffodil Society could not be formed." Mr. Jacob furnishes us with his reasons, comparisons and facts which are evident and galling to those who desire freedom, progress and a more commanding position, which it deserves. According to the Royal Horticultural Society's Book of Arrangements for 1913 (see page 57), I notice that the society is restricted and fettered by its own regulations, for there we read that "The society being registered as a scientific institution it is exceedingly doubtful whether it is not legally prohibited from offering money prizes at any of its shows to any of its members." The responsibility is placed on the shoulders of a few leaders. The Royal Horticultural Society cannot be blamed for the want of generosity. To my mind its own laws prohibit progress. This is an additional reason why we should agitate for a National Daffodil Society and why all lovers of this favourite flower should render what assistance they can in its formation.—J. E. D., *Talygarn*.

—I have read Dr. Lower's letter in your last issue with much interest and sympathy. I am inclined to think that if Dr. Lower could use his persuasive powers effectually on "G. H. E.," whose poem appears just above his letter (and who has previously only been known to us as a maker of *Poets*, not poems), one of the principal obstacles to the formation of a National Daffodil Society would disappear. But Dr. Lower would have to be a better pleader than I have been.—E. HERBERT CHAPMAN.

—As a Daffodil enthusiast and one who would like to see a greater diffusion of the dongs of the Daffodil world, I venture to address you on this much-vexed subject. Have the would-be promoters of the National Society carefully weighed the results of their movement, if successful? Three results would seem to me likely to follow: (1) A serious interference with the Midland Daffodil Society, if not its abolition. (2) Virtually a break with the Royal Horticultural Society. (3) The incurrence of a heavy financial responsibility. As to No. 1, can supporters of the Midland Daffodil Society loyally and with loyalty to such society promote another society which may supersede the Midland Society? As to No. 2, can the promoters of the new society ensure an attendance such as the shows under the auspices of the Royal Horticultural Society ensure? As to No. 3, why incur any financial responsibilities while the Royal Horticultural Society is willing to save all these? Is there not another way of obtaining our wants than breaking up one of our friends and breaking off with the other? I would suggest that a more universal membership of the Midland Society is one way, as if we put minds into that society's hands it might issue fuller reports and disseminate the news of the Daffodil world; and I would further suggest that a combined and

firm representation to the Royal Horticultural Society's committee might ensure a better service from that committee.—C. LEMESLE ADAMS. [Would the Midland Daffodil Society be willing to form itself into a National Society? If so, a great initial difficulty would be overcome. Working details could be arranged later by mutual consent.—ED.]

—I have been pleased to see in recent issues of THE GARDEN an article and letters respecting the formation of a National Daffodil Society. I am much in favour of the formation of such a society, as, although the Midland Society is most useful and well managed, it cannot possibly do the work which a National Society would be able to do.—J. MALLENDER, *Scrooby*.

Hardiness of *Campanula isophylla*.—The paragraph by your esteemed contributor Mr. Arnott on page 66, February 8 issue, prompts me to reply that plants have grown for years in Portobello in an open border facing east. They had become so large that advice was sought as to dividing them. The border was raised somewhat from the adjoining path and ran along the side of a dwelling-house. In another part of the town this plant grew well in an ordinary herbaceous border, but suffered much from wind. The soil here was distinctly light. I have grown the white form for many years in pots that were always frozen solid in severe weather. Then the foliage and shoots became quite limp, I presume through lack of available water, for as soon as a thaw came they never seemed any the worse. I grew them in a very draughty corridor, where they were only protected from rain. To get nice plants I encouraged new growth as much as possible as soon as the flowers were past, never allowing the soil to get dry, and I thus got very long growths, which by the end of July, throughout August and into September were simply a mass of bloom. The enclosed photograph is of a plant so treated. It was in a 7 inch pot, suspended by wires attached to a cord and pulley for convenience in watering. This plant measured exactly 63 inches from bottom to top, and had not been repotted for four years. It faced a slanting glass roof backed by a wall, so the flowers were all on one side. It was grown naturally without training, except that a few growths were twined about the wires supporting the pot. I was not aware this *Campanula* was considered tender. Mere cold may, I think, be disregarded, but strong wind and soaked foliage are certainly detrimental.—W. T. BASHFORD, *Portobello, Midlothian*.

—I have read with interest the remarks of Mr. Arnott in your issue of February 8 regarding *Campanula isophylla* standing the winter in some parts of the country but not in others. I have some plants, 8 inches across, growing on a rockery facing north-east, and up to the present time they are looking quite healthy, although, of course, we have had a very mild winter so far, but they have stood 10° to 12° of frost.—W. COLES, *The Gardens, Wallacefield, Croydon*.

—In reference to the note about this plant on page 66, it may be interesting to some readers to know that I have grown it in the open for several years in some east-facing vases fully exposed, and it has stood the severest frosts. I leave it undisturbed through the winter, and then break it up in the spring and plant it alternately with blue *Lobelia* round the edge of the vase, which makes a very pretty combination.—C. WILLIAMS, *The Gardens, Belmont House, Doncaster*.

— Seedlings of this plant raised during the summer of 1911 were planted out in the open garden at Lambay Island and remained there the following winter. We experienced no severe frost, but the ground was often very wet. These plants were eventually planted on a rock garden. They flowered profusely during the summer. Some years since the writer put out some plants from pots on a small rockery in Hertfordshire. Although these were partially protected during the following winter, only one plant out of about a dozen survived, and this did not grow strong enough to produce flowers. The conclusion is that this lovely *Campanula* is not hardy, and can only be grown in the open in localities where severe frosts are practically unknown. As hanging plants for windows, also for use in baskets during the summer, these subjects are invaluable. (C. RUSSELL, Ireland.)

RESULT OF THE ACROSTICS.

WE now have much pleasure in announcing the prize-winners in the Acrostic Competition. No one correctly solved more than four out of the eight set, and only two ("Elm Bampton" and "R. P. B.") had this number to their credit. In both cases the correct solutions were those of Nos. 1, 2, 6 and 7. According to the conditions already announced, the first and second prizes will be equally divided between these two. In five cases three correct solutions have been sent in, viz., by "Leander," W. Bond, L. A. Loudon, Mrs. Florence Jones and "White Lady." The acrostics correctly solved were Nos. 1, 2, 3, 6 and 7, grouped in various ways. The third prize will be divided between these five.

In the course of the next two or three weeks we hope to have time to study the results in detail, and we will then comment upon them. Guided by our experience in the present competition, we intend to outline another on similar lines, which we hope to conduct during the winter of 1913-14.

Prize-List.—Equal firsts: Mr. Macalister, Hamslade, Bampton, North Devon; and Mr. R. P. Brotherston, Tymmingham, Preston-kirk, N.B. Equal thirds: Mr. H. Tie-hurst, 43, Leander Road, Brixton; Mr. W. Bond, 60, Bostal Lane, Abbey Wood, Kent; Mr. L. A. Loudon, Loudon House, South Woodford; Mrs. Florence Jones, 21, West Bank Road, Birkenhead; and Mrs. H. R. Darlington, Park House, Potter's Bar.

Sixteen competitors sent in two correct solutions.

FORTHCOMING EVENTS.

February 28.—Beckenham Horticultural Society's Meeting and Lecture.

March 1.—Société Française d'Horticulture de Londres Meeting.

ANOTHER FUNGOID PEST. MYSTERIOUS DISEASE OF HYACINTHS AND DAFFODILS.

FOR several seasons past the Hyacinths potted up for trial purposes by my firm have failed in a very puzzling manner. They have started to grow, and then, when the tops have been 2 inches to 3 inches high, growth has stopped and many have failed to develop

Daffodils potted up with a view to exhibiting the blooms in March shared the same fate as the Hyacinths, only they were not quite so badly affected.

Last autumn we procured some nice fresh Kettering loam and potted up both Hyacinths and Daffodils in it after it had been turned several times and well aired. All bulbs have done well in this soil with the exception of Hyacinths which made splendid roots, and then, just about the time they were brought inside, the tips of the roots began to go brown, and after a week or two half the roots were quite decayed; at least, the worst specimens were. In some cases there was much less damage done.

Having exhausted every theory as to the cause of the damage, but leaning strongly to the idea of a fungus pest, I at last sent two good specimen bulbs in their pots to the Nottingham University, and Professor Carr, the resident botanist there, had the matter thoroughly investigated, and reports that the trouble is caused by the fungus *Pythium Barginum*, and that sections cut through the roots of the Hyacinths revealed the fungus in all stages of growth. Now, this is a decided gain to know what kind of enemy one is fighting, but at present I am quite in the dark as to what causes the fungus to attack the healthy roots.

After being potted the bulbs were placed on ashes, and were plunged in and lightly covered with Coconut fibre, a small inverted pot having been previously placed over the bulb. When removed from the plunging material, the plants looked really well, both as regards roots and tops; but, as before stated, the roots soon began to go wrong. The soil did not seem the least bit too wet, and looked beautifully fresh and sweet. Some Hyacinths potted in fibre are not attacked by the fungus, but have roots as white as snow. Last year some Daffodils grown in boxes for cut bloom were so badly affected that they were quite rootless, and could be easily pulled up by taking hold of the foliage. I was convinced that it was no fault of the bulbs, as some of the same varieties grown in fibre were all right. Now, this year, Daffodils treated in the same way, only planted in the Kettering loam, have done excellently, and have had roots protruding from the bottom of the boxes some 4 inches to 6 inches; yet in the same soil the Hyacinths have gone wrong. I am perfectly sure, from letters one sees in the columns of this and other gardening papers, that there are many sufferers from this pest, and a preventive or cure would be welcomed by many.

Only a few days ago one of our correspondents sent some Roman Hyacinth bulbs which had failed to flower. These were quite healthy and plump as to the bulbs, but when one looked for roots

A HANGING PLANT OF *CAMPANULA ISOPHYLLA ALBA* GROWN BY MR. W. T. BASHFORD, PORTOBELLO, MIDLOTHIAN. THIS MEASURED 5 FEET 3 INCHES FROM BASE TO SUMMIT.

their flower-spikes, while others have flowered but poorly. On examining the roots they have been found more or less damaged, in some cases entirely gone, in others partly decayed. For a long time we attributed the failure to eel-worm, or a similar whitish grub just visible to the naked eye. Consequently, we had the soil sterilised and hoped for an improvement; but the case was as bad as ever, and, unfortunately, a large batch of

there were none. There had been roots, but they had decayed completely away. Some bulbs potted up for trial from the same batch have given us better bloom than we have had for years, which proves that the fault lies with the soil or environment, and not with the bulb. One reason why I have ventilated this question is that those who are suffering from the effects of the same disease should not lay the blame upon the bulbs, but seek for the cause of failure in other directions. Another reason is that I have hopes of hearing from one of your numerous readers that he or she has been plagued with the same trouble and has found a remedy for it, for that is what we all want.

Loxham, Notts

J. DUNCAN PEARSON

THE ROSE GARDEN.

ROSE-PRUNING AND THE MILD WEATHER.

THERE are many readers, no doubt, much exercised in mind as to what they should do in the way of

"The Book of the Rose," by the Rev. Foster Melliar, the author refers to a very early season—1893—and says that the plants "bled" a great deal that year, owing to the very forward growths at pruning-time, and although the ground around was kept quite damp for some days by the overflowing sap, yet subsequent growth did not seem to suffer thereby.

Those who have had occasion to transplant their Roses will be fortunate in having retarded plants, and if one could have foreseen such a season, it would have been a good plan to have just raised the plants a little and dropped them back again in their own positions. I have plants that have been moved three or four times in the course of the last three months, and they are in a nice dormant condition. If we have no very severe weather, Ramblers will be very early; but, alas! they have a usually cruel May to go through, and I fear the result. These Roses, however, have a wonderful power of recuperation from the basal eyes of the lateral shoots. A year or so ago, some plants of Blush Rambler were so

SOME OF THE NEWER HYBRID TEA ROSES.

(Continued from page 82.)

Theresa (A. Dickson and Sons, 1909).—Semi-double flowers of variable but beautiful colouring, orange apricot, with carmine splashes on the outside of the petals, passing to flesh pink. Excellent habit of growth and free-flowering, fragrant and a pretty decorative variety.

Verna MacKay (A. Dickson and Sons, 1912).—A bright lemon-coloured flower, reminiscent of the beautiful garden variety sent out in 1911 called Carine. It may be a sport from that variety, but it is a very beautiful Rose that has only one fault, and that is it is not quite free from mildew. Free-flowering; medium-sized flowers of excellent shape, sweetly perfumed.

Viscount Carlow (A. Dickson and Sons, 1910).—An excellent bedding Rose, very free-flowering; colour, a bright pink on a cream ground. Distinct bronzy foliage and excellent habit of growth.

Viscountess Enfield (Pernet-Ducher, 1910).—A beautiful button-hole Rose of distinct colouring, coppery rose, with yellow shading. Not too good a grower with me, but it may improve in this respect, as I believe my plants were grafted.

Walter Speed (A. Dickson and Sons, 1909).—This can be best described as a yellow-tinted Antoine Rivoire, with all the good points of that fine old variety. It is, if anything, better shaped, and will, no doubt, find its way occasionally on to the exhibition bench; but it is a good garden Rose, though we have so many of these whitish Roses, tinted yellow, that very many of them will fall out of cultivation. Walter Speed is, however, one of the best of them all, and when better known will become popular. Next week I will conclude these notes with particulars of a few of the newer decorative Tea Roses.
Southampton. H. E. MOLYNEUX.

THE GREENHOUSE.

NOTES ON CHRYSANTHEMUMS.

EVEN since the first batch of cuttings was put in, the weather has been favourable for them, except in the matter of damping in cases where amateur cultivators have been obliged to rely on cold

houses or frames in which to carry out propagation. From this cause, and in the circumstances referred to, some loss has been sustained. The newly-rooted cuttings have, however, grown very nicely indeed, as there has been no frost severe enough to check them. Such frost, however, may be experienced, and, if so, growers must duly protect their plants, as the young stems are rather tender.

The Potting of the Rooted Cuttings.—It is not wise on the part of the cultivator to allow the newly-rooted cuttings to remain too long in the small pots. Time is precious, and it soon passes; and if the young plants are not closely watched and potted on when they need more rooting space

A NEW AND DISTINCT POLYPODIUM FOR THE GREENHOUSE. (See page 93.)

pruning in this exceptionally early season. They are wondering whether, instead of waiting till the usual time of the second week in March for the hardier sorts and early April for the Teas, they should start almost at once, seeing that growth is so wonderfully forward. In some cases I have even seen bloom-buds forming on the new shoots. Now, my advice would be to defer pruning until the usual time, for this reason: If we prune now or at the end of February, or even early in March, our plants are sure to start into growth almost at once if present conditions prevail. And therein would be the risk, because April frosts would almost certainly cripple the growths that should, under normal conditions, give us our best blooms. In

forward when a frost came that they seemed as though they had been singed; yet I did not cut the young growths away, but allowed them to develop, and the plants flowered as though nothing had happened. The advice now given is that Roses should not be pruned earlier than usual in this forward season. When pruning is done, it must be mostly to dormant eyes, except in the case of decorative Roses. These may have a growth or two left much longer, and although it may be advisable to cut this growth away later on when others are developed, it serves the good purpose of slightly retarding lower eyes and also preventing a too severe "bleeding" of the sap.
DANECROFT.

and fresh nourishment, they quickly lose ground, as it were. A light, sandy compost is the best for the plants generally. Some rotted manure should be mixed with equal quantities of fibrous loam and leaf-soil, at the rate of one peck to five pecks of the combined parts. At this potting, too, a 3/4-inch potful of bone-meal may be added to a bushel of the prepared compost, but no concentrated manures, because the roots to each plant are not very numerous. Avoid firm potting, too; simply press down the soil gently with the fingers and keep the roots near the surface, removing any of the loose cutting soil from the top.

A Good Position for the Plants.—When first repotted, place the plants fairly close together on a stage, or in a frame in the Southern Counties, for a week or so, and during that time avoid watering the soil unless it gets rather dry, as, if it is fairly moist when used, two or three light syringings will be sufficient and the roots will permeate the new compost more freely. Then water through a fine-rosed watering-can and spread out the plants so as to admit air among them freely. They should be placed close to the roof glass if in a greenhouse, and on a bed of ashes if in a frame.

Ventilation and Mildew.—After the work of repotting has been done, do not admit air to the plants for several days, and afterwards apply it in such a way as to avoid cold currents of air blowing directly on them. They must be well ventilated, as fresh air in mild weather is very essential; but cold draughts cause the spread of mildew and check free growth. Any plants affected by mildew must be dealt with quickly, else many leaves will be lost. Flowers of sulphur dusted on the parts will be found a good and simple remedy.

Propagation in Spring.—Plants that are to be grown with single stems and to bear one bloom only are best raised from cuttings inserted from February 20 to April 20. The early varieties must be propagated in April, and the naturally late-flowering ones at the end of February and during March. Some cultivators insert several cuttings in a large pot or box, but beginners should insert one cutting in a small, deep pot; then, when sufficiently rooted, repot at once and there will be no check. It is very important that the late-rooted plants be grown on steadily, and not forced in a high temperature. The cuttings root quickly at this season, so that a stock of young plants is soon secured.

A NEW FERN.

(POLYPODIUM IRIOIDES PENDULUM GRANDICEPS.)
 THE new Fern illustrated on page 92, and having the misfortune to bear the above name, was referred to in our issue of February 15, page 87, under "New and Rare Plants." It is very distinct in appearance, with forked fronds of leathery texture, which are more suggestive of the Stag's-horn Fern or Platycerium rather than a Polypodium. The fronds are of a deep rich olive green colour, and inclined to be of pendent habit. Old specimens are said to make beautiful basket plants, producing trailing fronds a yard in length. The plant was introduced from a garden in Queensland.

THE FLOWER GARDEN.

SOME GOOD ANNUAL FLOWERS FOR EDGINGS.

IN THE GARDEN for January 4 there was an article on the use of annuals for edgings to the kitchen garden paths, with an illustration of a path bordered by white Candytuft. In addition to the kitchen garden, there are the more ornamental parts of the garden where the paths might well be edged, at very little expense, with annual flowers, particularly those of a low-growing character. The accompanying illustration shows an edging of Alyssum Webb's White Carpet, that made an attractive

A BROAD EDGING OF ALYSSUM WHITE CARPET, A HARDY ANNUAL THAT MAY BE SOWN OUTDOORS IN SPRING.

edgings, among them being *Leptosiphon hybridus*, (a little gem that likes a sunny place), *Mignonette*, *Virginian Stock*, *Viscaria cardinalis*, *Erysimum perofskianum*, *Nemophila insignis* (should not be sown where cats are troublesome), *Phacelia campanularia*, *Saponaria calabrica*, *Silene pendula compacta*, *dwarf Godetias*, and *Sarivatala procumbens* Little Gem. H. H.

LILIES: A CAUSERIE.

(Continued from page 84.)

LILIUM HENRYI is still high-priced, but well worth 5s. for a good bulb. It has such a fine effect in the border, and is very amiable in most gardens. I have been told that its native home is a ledge on a cliff face, and most frequently there is but little depth of soil for its bed, so that, growing wild, it has never been seen exceeding 4 feet in height, and its arching habit well fits it to hang out over the precipices. I have sometimes seen it in gardens, staked stiffly upright, and then all its grace is gone. I would as soon see Solomon's Seal staked to stand up as does a Guardsman. There is a photograph of a fine head of *L. Henryi* in a recent American gardening magazine that well illustrates this. There must be nearly fifty flowers and buds on that stem; but it appears a confused mass instead of the graceful groupings of opened and unopened flowers that may be seen on a stem allowed to bend over to a horizontal position in its own way. If shooting up through thin shrubs, the lower portion would be supported, but if among low plants it is, perhaps, as well to stake the lower 2 feet or 3 feet of the stem, doing so before it has grown more than three feet high, and cutting the top of the stake off at about that height. *L. Henryi* flowers throughout August, which adds to its value, as it just precedes *L. tigrinum* in time of flowering.

This last is, in fact, the latest-flowering Lily that it is safe to trust in the open ground in most British gardens, that glorious, stately creature, *L. sulphureum*, being too precious to risk outdoors save in Cornish, South Irish and other singularly well-favoured gardens. The Tiger Lily is too well known to need description here. A large planting of it is a fine sight when in flower; its warm but soft orange ground colour is rare in gardens at any season, and one of those I most enjoy. I had a good effect this autumn from a bold group of its fine and late-flowering variety *splendens*, growing among white *Phloxes* and various shrubs with silver variegation of leaf, among which *Galtonia candicans* was scattered at irregular distances, the whole backed by purple-leaved shrubs and trees, such as *Prunus Pissardii*, *Purple Hazel* and *Barberry*, *Enonymus europæus*, and that most wonderful of all purple-leaved things, *Paul's Purple Peach*. How I hope they will all reproduce the picture again and again! But here *L. tigrinum* wearies of my lime-charged soil in two or three years. The variety named *Fortunei* is also very good, and may be known by its grey, woolly stem and earlier flowering. I do not care much for the double-flowered form, for though its individual

feature in the garden for nearly four months last year for the mitral outlay of sixpence, the cost of the seed. The border at the back of this edging was filled with *Horace Martyn Chrysanthemums*, and when these were in bloom during the early autumn the effect was most pleasing. It will be noted that the edging of *Alyssum* is a broad one. This is important. A narrow edging, if of any considerable length, looks puny and out of place.

The chief merits of these annual flowers are their easy cultivation, effectiveness and cheapness. It is only necessary to sow the seed thinly in early April, subsequently thin the seedlings, and keep those that remain free from weeds. In addition to the *Alyssum* and *Candytuft* already referred to, there are a number of annuals suitable for

flowers last rather longer, they never make so fine a display as those of the two varieties previously named. For those with patience, a spare corner and plenty of leaf-mould and good loam, it is easy to raise a stock of the Tiger Lily from the bulbs so freely produced in the axils of the leaves, and which, if well treated, should flower in the third or fourth year.

There remains but one group more that I can rank in my second class of Fidos, the Orange Lilies being the only other trustworthy came-natured settlers here. To reconcile the synonyms, sort out the varieties, and group the subspecies around

even as Poppies often do in East Anglia, and it was a pleasant thing to see a corps of Alpini returning, after some mountain manoeuvres, to the Barracks at Dione, a tired and travel-stained company indeed, but many of them carrying bunches of flowers, and especially of Orange Lilies. I have never yet seen Mr. Thomas Atkins returning from Aldershot with a bunch of *Gentiana pneumonanthe*. I wish a millionaire would let me plant a sloping hay-meadow with all the varieties of Orange Lilies his purse and the nurserymen could provide, and let me go and stare at them annually before they fell, whether before the

struggle to grow it, and I believe stiff soil on a sunny bank of rockwork might make it happy. *Lilium Brownii* has lived happily for some dozen years in a peat bed, behind a Cactus bank, where American *Erythroniums* also flourish. The bank shades the midday sun from its roots, and the Lily's great flowers stand up to the sunlight. It is exquisitely beautiful in shape and colouring; the brown outer surface of the trumpets reminds me of some beautiful Japanese carving in ivory, in which the natural brown outside of the tusk has been left where required. I hope my written praise will not affright it.

As the New Year is still so young, surely it is in place to make some good resolutions. I must make a point of growing more Lilies from seed, and I strongly advise all who have followed me thus far in these notes to be on the look-out for fresh, ripe seed whenever available, and to sow it at once. The charming group of *L. rubellum* on page 95 shows what has been done at Kew lately, and what you and I ought to do.

Waltham Cross. E. A. BOWLES.

DAFFODIL NOTES.

Early Flowers in Pots.—As the bulbs I force are an *omnium gatherum* from many sources, I may, I think, take my own experience as a sample of that of others. All the same, I hope it is not, for my flowers so far (February 13) have not been as large or as even as usual, and in some cases the foliage has been more or less distorted. Curiously enough, Dutch bulbs have been more satisfactory than British-grown ones, which is not the case as a rule. As bearing upon this I had a certain variety grown in 1911-12 in five different parts of the British Isles, and also in Holland. I potted last autumn a sample from each place, six in all. Up to two days ago these lived in a cold shed, and afterwards in a cold frame, so they have not been forced. At the time of writing, the Dutch-grown ones are the picture of health, while the others all look rather yellowish, and those from the warmest district the worst of all. Each one was potted on the same day and in the same mixture of soil, and all along each has had precisely the same treatment. This is a puzzler. My man and I have talked it over and talked it over, but we have got no "forwarder." All I can say is that it seems to have some bearing on our experience with the other bulbs. Perhaps some reader can throw some light on this.

Orphee and Fairy Queen in Pots.—My good opinion of these for pot work at the end of January has been confirmed. For a bit of red colour at this early period of the year I know nothing better than Orphee. It beats *Barri conspicuum* into "a cocked hat." I always think the merits of this grand old border variety as a pot plant are greatly overrated. The two have been in flower for the last week in my greenhouse, and you might as well compare the veriest daisy to one of Mr. Hayward's exquisite flower paintings as old *Barri* in a pot to its less-known and more-than-rival Orphee growing in the same receptacle. The well-defined red edge of the cup always shows up

A BED OF *LILIAM BROWNII* AT KEW, WITH A CARPETING OF IRISH HEATH.

a central head of the clan. In this group is a work awaiting another Daniel to come to judgment and a Solomon with a knowledge of everything from "the Hyssop on the wall to the Bishop on the bench," and perhaps then we should still need a special enquiry under a stipendiary magistrate to tell us whether or no we might believe the evidence in an ordinary sense or only in a police-court one. Anyway, I shall not attempt it. I find such divergence of opinion among the highest authorities, Nyman, l'Abbé Coste, Baker, &c., as to where *L. bulbiferum* ends and *croceum* or *davuricum* begins in wild or cultivated forms that I just grow what I can get of any of them. I used to believe *bulbiferum* invariably grew bulbs, and thereby was easily distinguished from the others; but whenever I have come across the glowing Fire Lily growing wild, never a bulb has it given me to carry away and grow. I have seen it on rocky ledges, single-flowered and only inches high, on the Gothard, a glorious splash of colour against the grey rocks. Once, above a damp ravine, the Lilies made lines of fire along the ledges, and, below, *Saxifraga Cotyledon* shot out ostrich feathers of brilliant whiteness. But I think it pleased me even more when its flowers floated above the Meadow-grasses, *Campanulas* and *Salvias* of Tyrolean hayfields,

mower or the wind. Fading hay-meadows, they look well enough in an ordinary sunny border, and *umbellatum*, whether it be right to call it a *davuricum*, *bulbiferum* or a hybrid from elegans, is one of the best for most purposes. The croceum of cottage gardens is a great favourite of mine, as its colour is so good and true an orange.

Of my third class—the hoity-toity beauties, I feel, may be offended at any moment—I should like to speak in whispers, or have this paragraph set in the smallest type, lest I scare them. *L. chalcidonicum*, the glorious scarlet Martagon, is one. Now and then it has appeared quite happy here, and sent up tall stems furnished so neatly and overlappingly with the white-edged leaves so distinctive of its identity that I have believed all was well; then for a season or two inch-high stems and blind buds. I think it loves a stiff soil, its feet in a cold pond in summer, but its head in a furnace; for I have often known it to thrive marvellously in the clay soil of Cheltenham, and here it seems to suffer most after hot summers. It comes from Greece, so should love heat, and is said to stand drought; but I have often known *candidum* to flourish well on stiff clay if not planted deeply, and especially if in sloping ground. The pure scarlet of *chalcidonicum*'s flowers is so glorious that it is worth a

so well and the pale primrose perianth keeps quite stiff and never flops. Both stem and leaves are good. The shapely little Leobon Fairy Queen also lends itself to this unnatural treatment. If comes so easily, it is so floriferous, and it is of such an exquisite shape that, even without its nice spicy perfume, it would be a variety to be highly recommended for this purpose.

Cultivation in the Open. This is such an abnormal season that a word as to the benefits of the constant stirring of the surface of Dattoh beds and dumps may be given now. Two important factors in Dattoh cultivation are deep digging before planting to promote, among other things, good drainage and warmth, and in the spring when the little noses begin to peep above the ground, the constant loosening of the surface to give the plants air. This latter operation is best performed by the use of an appropriate-sized "Buco" cultivator. It is altogether a more satisfactory tool than the old hoe. It does the same work, but much quicker and more thoroughly.

Helxine Solierolii.—The possibilities of using this as a carpet plant for bulbs in pots struck me last autumn, and I tried the experiment on a small scale. I have now a small pan of W. P. Milner and another of Winter Cheer Hyacinth with the soil nicely covered all over and the bulbs just about to flower. The effect is excellent. My procedure was as follows: I put small cuttings of Helxine all over the pans in September, and when these were getting hold, I put in the bulbs. They have been in a frost-proof frame with practically no heat ever since. This plant strikes so easily that there is no difficulty in having a sufficient stock always at hand to carpet a goodly number of pots or pans.

Packing Flowers to Take to Show.—I have been asked by one or two correspondents to give a few wrinkles on how to pack for show. I have had a photograph taken of a partly-filled box, and, as it has turned out a pretty good one, I hope to use it next week to illustrate an article on this subject. Getting one's blooms to the show in the best condition possible is one of the essentials of success. JOSEPH JACOB

SCIENCE IN HORTICULTURE.

THE RIPENING OF FRUIT.

Natural Ripening.—A knowledge of the essential conditions regulating the ripening of fruit, and especially of soft fruit, is of peculiar interest to gardeners. Everyone is quite familiar with the change that takes place whereby a sour Apple gradually changes its character and becomes sweet, and also how a green, hard, bitter Date fruit gradually loses its astringency and becomes mellow and pleasing to the taste.

With regard to this subject, Gerber some years ago conducted researches with three types of fruit, namely, those containing (1) in the acid, as in the Apple; (2) tartaric acid, as in the Grape; and (3) citric acid, as in the Orange. He showed that during the ripening changes respiration was very

active; that oxygen gas was absorbed, and that much carbonic acid was generated. As ripening advanced, the acid was gradually changed to sugar, as was also any starch that happened to be present in the fruit. He also stated that the tannin which imparts the bitter taste to the unripe fruit was destroyed by oxidation. Furthermore, it was discovered that these changes would only take place within certain limits as to temperature. Fruits containing malic acid required only a comparatively low temperature, hence the perfect ripening of Apples in these latitudes; while it explains also why Apples, at botanically ripe (that is, the seeds matured, but the flesh still sour, will ripen after harvesting.

Tartaric acid fruits require a medium temperature, hence the necessity of allowing Grapes to ripen in this country on the Vines. Citric acid fruits require a still higher temperature, as all gardeners know who attempt the cultivation of Oranges. But the changes that take place in fruit do not stop at the "ripening" stage. Fermentation follows and the sugar is changed into alcohol, volatile acids and perfumes, to be succeeded, in turn, by still further changes that gradually pass into decomposition of all the softer tissue. These latter changes also are influenced by temperature;

When the State of California first began having a direct, apparently suitable for these popular and profitable fruit. But it was found that while they grow well and produce fruit yet the conditions are not favourable for the completion of the ripening process. It is therefore necessary, if the projected new industry is to succeed, that some method be devised to ripen the fruit artificially. Mr. Swingle of the Scientific Staff of the Department of Agriculture at Washington has charge of the experiments. When the seed of the Date has reached maturity, the flesh of the fruit is so bitter (due to the presence of tannin) that it is quite uneatable, and the problem is how to artificially alter the tannin so that it will lose its astringency. According to Swingle, there are two essential factors influencing the change—heat and moisture. In Arizona the autumns are warm enough, but the air is too dry; therefore the experiment has been made to harvest the botanically ripe but still bitter fruits and subject them to a moist heat of 43° to 49° Cent., when ripening takes place within twenty-four hours. The tannin collects in a layer of large cells close to the skin, and undergoes a change in character that destroys its astringent property. (This tannin layer may be seen as a dark ring on cutting a Date fruit in half.)

THIS GROUP OF LILIUM RUBELLUM WAS RAISED AT KEW FROM SEEDS.

hence the use of cold storage as a means of arresting such after-maturation results. According to a recently-published Hungarian report on fruit storage, the temperature most favourable for the good preservation of Apples is from 2° to 3° Cent., that is, 2° to 3° above freezing temperature.

Artificial Ripening.—Most interesting and instructive experiments in the artificial ripening of Date fruit are at present in progress in the United States. The results obtained so far are very suggestive, and British fruit-growers would do well to keep in touch with the work. Algerian Dates have been introduced to cultivation into certain

But perhaps the most interesting experiments relating to the artificial ripening of bitter fruits are those carried on by Professor Lloyd of the McGill University. By a series of observations, experiments and inferences, and guided by the previous experience of Gore of the United States Department of Agriculture, this worker was led to believe that the cause of the tannin change was not directly due to oxidation, but to the presence of carbonic acid gas produced by oxidation. In order to test this theory, he constructed a metal vessel in which the unripe fruits could be placed and subjected to the influence of an atmosphere

of pure carbonic acid gas under any desired pressure. With this apparatus and at 15lb. pressure the fruits lost their bitterness in about thirty-six hours, while at a 45lb. pressure the ripening change was effected in about fifteen hours. This method has the advantage of great simplicity and cheapness. Firm, unripe, bitter fruits, such as Dates or Persimmons, can be sent long distances to market, and made ripe and ready for immediate sale and use within fifteen hours of delivery, or, in case of a glut, kept in cold storage until the state of the market justifies their immediate ripening.

DAVID HOUSTON,

Royal College of Science for Ireland.

TREES AND SHRUBS.

THE DAPHNES AND HOW TO GROW THEM.

DAPHNES are an extremely ornamental genus of plants, esteemed both for their beauty and the delicate fragrance of their flowers. A large number

D. oleoides is a plant of many synonyms; *D. fioniana*, *D. collina* and *D. neapolitana* are identical with this. It forms a neat, rounded bush some 2 feet to 3 feet high, producing rose purple flowers in small clusters at the extremities of the branches. It makes an attractive shrub for the rock garden, but is not so showy as some others.

D. Laureola and its variety *Philippii* and *D. pontica* are stout, evergreen shrubs that succeed admirably under the shade of other trees, including Beech; they also grow freely in almost any kind of soil. While those already described are all indigenous to Europe, *D. Genkwa* comes from far Eastern Japan, and is one of the most captivating of this genus. Unfortunately, it is not quite hardy, and is best grown against a low wall. The flowers, as in our common Mezereon, are borne on the naked branches in advance of the leaves. Individually they are very large, of a rich shade of lilac and sweetly fragrant. It reaches a height of 2 feet to 3 feet, or rather taller when grown against a warm wall.

while the stems revel in sunshine. It forms dense cushion-like masses of trailing stems some 9 inches to 12 inches in height, the flowers being borne in dense terminal heads. The buds are bright crimson but when fully open the tubular, wax-like flowers are a glowing pink. It is a subject one enjoys having easy access to when in flower, and if a drift is arranged on the rock garden about a yard above the path, each passer-by may freely partake of its delicious fragrance.

D. rupestris occupies a similar position among the dwarf kinds as *D. Genkwa* holds among those of taller growth. It is a diminutive species, of slow growth, so that one rarely comes across a large-sized specimen. It is most suggestive of *D. Cneorum* in the flowers, but these are larger and even more waxy in texture. They are borne in clusters, and the colour is a glistening pearly rose pink. In its native haunts *D. rupestris* grows in fissures of limestone, in a soil that is described as peaty loam, while on rock gardens it appears to succeed best in a well-drained but

1.—STANDARD APPLE TREE CUT BACK READY FOR GRAFTING.

2.—THE GRAFTS INSERTED AND TIED WITH RAFFIA.

3.—THE GRAFTS COATED WITH CLAY TO ASSIST THE UNION WITH THE TREE.

are among our hardiest shrubs, those of tall growth being eminently adapted for grouping in shrubberies and woodlands, while the dwarf kinds form a group of exquisitely beautiful rock plants. The commonest and best-known species is *D. Mezereum*, whose fragrant, reddish purple blossoms wreath the naked branches in January and February. It attains a height of 3 feet to 4 feet, with erect branches, at the nodes of which the clustered flowers are borne. It succeeds best in a sunny position, or with only partial shade, and grows freely in ordinary garden soil. Its precocious beauty and charming fragrance are best enjoyed when it occupies a foremost position in the shrubbery. Besides the type, there is a pink-flowered form, also single and double white-flowered varieties.

D. blagayana is a prostrate species with creamy white, tubular flowers, arranged in dense heads on the terminal points of the branches. The leaves are evergreen and chiefly confined to the points, around which they are arranged in the form of a rosette. It rarely exceeds 6 inches in height, spreading out in all directions. It soon forms a rich carpet, succeeding best in a mixture of loam, peat and sandstone chips in a partially shady position, the scented flowers being in season during March and April. *D. blagayana* and *D. Cneorum* are two of the most select Daphnes, easy to procure and not difficult to cultivate. The Garland Flower, as the latter is called, is a native of the great mountain ranges of Europe, and is eminently adapted for the rock garden. The roots appear to enjoy close contact with the cool rock surface,

cool site, planted in a compost of loam, peat and stone chips, and with plenty of rough grit in the soil. *D. odora* and its variety *Mazeli* are exceedingly popular as greenhouse plants, as, unfortunately, neither is hardy enough for outdoors, except in very favoured districts. The flowers of *D. Mazeli* are pinkish white and borne on short laterals, being in season from December till spring. The flowers of *D. odora* are in clustered terminal heads and appear in spring. *D. odora* and *D. Mazeli* are slow in growth, and are usually grafted on a commoner kind. They make pretty pot plants, and are best grown in a mixture of peat, loam and silver sand. The flowers are so intensely fragrant that a small plant is capable of filling a large room with its odour.

Coombe Court Gardens.

THOMAS SMITH.

GRAFTING STANDARD APPLE TREES.

THE art of grafting is old, dating back to very remote times. It forms a very ready means of propagating stock of many plants that are

working young fruit trees, also for Rhododendrons. Cleft and crown or rind grafting are generally resorted to when the stock is considerably larger than the scion. The latter method is very clearly illustrated on the opposite page. As shown, the method is usually applied to working stocks with large, woody branches. In cleft-grafting the ends of the stock are generally split with a chisel. The scion is then cut wedge shape to fit the split stock. As can readily be understood, this method has many objectionable features. The split wood is a fruitful source of decay, as it seldom gets properly covered with healing tissue.

Crown or Rind Grafting as illustrated is the best method for dealing with large stocks, and is a very quick method of replacing a poor or otherwise unsuitable variety of Apple or Pear, and for this purpose is generally practised in fruit-growing districts. The stock, naturally, should be healthy and fairly young. In the case of Apples in orchards it is best to work them with strong-growing sorts, such as Bramley's Seedling or Newton Wonder.

In preparing such trees for grafting, they should be headed down during January, leaving the stumps long enough to cut back to fresh wood when grafting. This may be done any time during the spring,

when the sap is running freely, as it is essential that the bark should part easily from the wood. The tree figured was grafted about the middle of April.

The scions required should be selected during the winter, tied up and securely labelled, when they should be laid in at the north side of a wall or hedge. In such a position they remain in a dormant state until required. Grafting wax or clay will be required to cover the union of stock and scion and exclude the air. The clay should be well worked up with some soft meadow-hay; this binds the whole together and prevents it from cracking.

Everything being ready, the scions should be stood in a vessel of water to keep them fresh. The stumps of the stock should then be cut back the required distance with a fine

pruning-saw, afterwards paring them smooth with a sharp knife. The scion should then be selected from one of the shoots, cutting it some six inches long. From 2 inches to 3 inches of its bottom end should then be pared off in a slanting direction; the practised hand will do it with one cut. A slit should then be cut about the same length in the bark of the stock in the desired position, raising the edges of the bark with the haft of a budding-knife, when the scion can readily be pushed into position and secured with a string of matting, as is shown in No. 1, where the stock is shortened back ready for grafting, with one scion shown in position.

No. 2 shows the same stock with all the scions inserted and tied in position, while No. 3 depicts the operation of covering the points of union with clay completed, during which operation a vessel of water should be handy to dip the hands in, else difficulty may be found in smoothing the clay over. No. 4 shows the same tree some eight months afterwards, where it will be seen that each graft has united and also made considerable growth. In this case the variety is Cox's Orange Pippin. No. 5 shows a stock worked with Bramley's Seedling. This example was grafted during the last week of May, and shows the tree pruned after the second season's growth. Until the scions unite with the stock and commence to grow, the stock will persist in throwing out shoots from latent buds. They must be kept rubbed off as they appear. J. C.

4.—THE SAME TREE, SHOWING THE FIRST YEAR'S GROWTH OF THE GRAFTS.

slow on their own roots, and on this account is valuable in the nursery. Apart from that, it serves many other useful purposes. For example, a strong stock may give vigour to an otherwise weak-growing plant. On the other hand, it may have a dwarfing effect, as exemplified by the use of the Paradise stock for Apples and the Quince for Pears. Again, many Pears are only fertile when double grafted; for example, a Pear stock may be worked with, say, Beurré Clairgeau, and the desired sort, such as Gansel's Bergamot, grafted on that again.

Apart from the fact that stock and scion should have some natural affinity, and should, of course, be in a suitable state of growth—and in this respect the stock should generally be in a more forward state than the scion—the one great essential in successful grafting is the fact that the cambium layer, or inner bark of both stock and scion, should coincide and come in contact with one another. Of course, quick, clean workmanship is important as in all branches of propagation.

The simplest and most generally practised forms are whip, saddle and wedge grafting. In all three forms the stock and scion should be as nearly as possible of one size, so that their barks may coincide. Whip and saddle grafting are largely practised for

5.—A SIMILAR TREE TWO YEARS AFTER GRAFTING. NOTE THAT PRUNING HAS BEEN DONE AND THAT A NUMBER OF FRUIT-SPIRES ARE FORMED.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Pleasure Grounds.

Pruning.—Specimen Hollies, Yews, Portugal Laurels, also the more tender shrubs, may be pruned without any fear of damage from frost.

Lawns.—These should be swept over as often as may be necessary to remove worm-casts, using the heavy roller on them whenever time permits, a loose, spongy lawn being often badly marked by the mowing-machine during the summer.

Edgings.—It is usual to go over the edges of the paths at least once a year to keep them in good condition, and when there is a lot to do it should be taken in hand before the stress of work in other ways comes along.

The Flower Garden.

Gladioli.—These are almost indispensable and for an early show of bloom in the borders they may be planted at once. Plant a few inches below the surface in well-prepared ground, not stinting a little manure for them, though this should not be of too rank a nature. For cutting purposes they may be planted in beds 4 feet or 5 feet wide, and for a succession, beds may be planted every three or four weeks till May. It is full early for starting them in boxes for bedding-out purposes.

Plants Under Glass.

Stove Climbers.—Many of these will be now breaking into growth, and such of them as have been kept dry at the root to prevent too early starting should now have a thorough soaking of water, after giving them a top-dressing of suitable soil with a little bone-meal or other manure added. If in pots, some may need repotting, and this should be done before they make much growth. Specimen Allamandas, Stephanotis, Clerodendrons and Bougainvilleas that may be wanted for a display later on in the season may be left in a cool house for some little time yet if it is thought they are likely to flower too early.

Potting Stove Plants.—This is about the best time to go through the general batch of stove plants, potting all such as require it, relegating any old and unsightly plants to the rubbish-heap, thus making more room for the younger and more useful ones, which from now will be making rapid growth.

Compost.—This should be of a fairly open nature, and if it consists of two parts loam, one of peat, one of leaf-soil and one of sand, with a little old mortar rubble, wood-ashes and bone-meal added, it will suit most stove subjects, including Ferns, though where a quantity of Crotons are grown, a little more holding compost should be prepared. Find they colour and grow better under rather more generous treatment than that given to the ordinary run of stove plants.

Chrysanthemums.—The early propagated varieties that may have been rooted singly in small pots should now be in fit condition for potting on. Three-inch or 4-inch pots are the best, and, providing the plants are well rooted, good firm potting should be practised. The stage or shelter in a cool house is a good position for them after potting, though a quite cold frame will suit them equally well providing every care is given to watering, airing and covering up at night in case of frost.

The Kitchen Garden.

Asparagus.—Beds that may have had the surface soil removed in the autumn and probably a dressing of manure given should now be covered up again by cutting down the sides of the beds and shovelling the soil from the alleys back on to the surface of the beds. If a good dressing of well-rotted manure, or even old Mushroom-manure and leaves, can be put on before the soil, so much the better, as it will secure a greater length of head before the shoots push through the soil, and, where people like Blanched Asparagus, this will help matters considerably.

French Beans in Pots.—Plants in bearing should be top-dressed with good rich soil and manure, or, if the size of the pots does not allow of this, they must be kept well fed with manure-water. Keep up the supply by sowing fresh batches at short intervals.

Potatoes in Pots.—These, as they push through the soil, must be given a good light position, as

obtained top growth usually results in an indifferently crop.

Lettuce.—Plants raised from seed sown in the autumn may now be transplanted, choosing a time when the soil works well. A warm border is the best to secure an early crop, and if a single row is planted quite at the foot of a wall facing south or south-west, it will make a material difference to their earliness.

Fruits Under Glass.

Disbudding Vines.—Vines shut up early in the year and brought along steadily should now be in a forward enough condition for the first disbudding. Commence by taking off the shoots that are badly placed, and for the time being leave two that are showing bunches to each spur. These may be reduced to one when the size and shape of the bunch can be better judged.

Ventilation.—Earlier houses will need considerable attention as to air, the early morning being the most critical time, and I very much favour the system of giving a little before the temperature rises very much, increasing it, of course, in accordance with the weather conditions prevailing, always closing up in time to take full advantage of the sun-heat, which even at this season is none too plentiful.

Orchard-House Plums and Apricots should now be in full bloom, and on fine, warm days artificial fertilising should be practised, unless a hive of bees near by have found out the trees in flower, when they will probably do all that is necessary. Rather warmer conditions should now prevail, but at present no real effort should be made to push them along.

Hardy Fruit.

Cuttings of Bush Fruits.—To keep up a supply of young trees it is a good practice to put in a batch of cuttings every two or three years, and though rather late, they may still be made and inserted. Strong-growing shoots are the best, and I prefer to put them in on a somewhat shady border. Here they root readily, and if shifted to a more open position next winter they will soon make good plants.

THOMAS STEVENSON.

(Head-gardener to E. Moratta, Esq.)

Woburn Place Gardens, Adlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Carnations.—Where Carnations were potted up and wintered in cold frames, they will now require attention as regards watering, although it is still advisable to keep them rather dry. The lights should now be removed entirely in fine weather preparatory to planting.

Hoeing.—As soon as the soil is in a satisfactory condition, Wallflowers, Forget-me-nots and other spring bedding plants above ground should have the soil between the plants stirred with the Dutch hoe.

Tropaeolum speciosum.—This lovely climber is undoubtedly erratic, proving well-nigh indestructible in some cases, while in others no amount of coaxing will induce it to do well. So far as ascertained, however, the two essential conditions to success seem to be a free root-run with a cool bottom. When once it takes to a position, it should be left severely alone. The present is a good time to plant.

Wistaria chinensis.—There is a popular fallacy that this beautiful twiner is comparatively tender. I have had this plant under observation for over forty years, and have again and again seen it exposed to 25° of frost with impunity. For a high wall it is an ideal plant, and those intending to give it a trial should select a site for it now and, after excavating a pit, fill it up with a barrow-load of good turfy loam, with a view to planting a week or two hence.

The Rock Garden.

Planting.—Young plants which were rooted in autumn and wintered in frames should, if hardy, now be planted if the weather conditions are favourable. In the disposal of the various subjects their respective requirements as to soil and situation must be kept clearly in view. Where difficulty is experienced in finding room for real gems and it is deemed inadvisable to extend the rockwork, do

not hesitate to sacrifice some of the coarser subjects, as they can probably be accommodated in beds or borders.

Plants Under Glass.

Liliums.—Where not already attended to, the potting of Liliums should no longer be delayed. Auratum and the varieties of Lancetolium are all worthy of a place. Only from large, well-ripened bulbs can good results be obtained, and the price should only be considered in relation to quality. Peat is not essential, but a compost of turfy loam, fibrous peat, dried cow-manure and some clean sand is an ideal one. Always leave sufficient room for top-dressing. Keep dry and cool till the bulbs commence to grow.

Eucomis punctata.—This is a desirable bulbous plant for a cool house; moreover, it is very cheap. Put up into 6-inch or 7-inch pots, using a compost of three parts turfy loam to one of dry cow-manure and a dash of clean sand.

Forcing Plants.—Later batches of bulbs and other forcing plants can now be brought on with very little fire-heat, especially during the day. Plants to be placed in rooms will stand longer in condition if stood in a cool house for a few days prior to being placed in the rooms. Many forced plants will be of future service, and should be cared for. Deutzias, Philadelphuses and several other shrubs should, when they have done flowering, be returned to heat to finish their growth.

Fruits Under Glass.

Figs.—Early Figs in pots will now require some rise in the temperature. They will also need an increase of moisture, both at the roots and in the atmosphere. Later trees may now have a night temperature of 55° and be syringed daily, but they should be kept fairly dry at the root till growth is active.

Tomatoes.—Autumn-sown plants will now have their fruits well set. To facilitate the development of the fruits, only a limited number should be retained, and after the requisite number have set, the leading shoot should be pinched and all laterals, on their first appearance, be rubbed out. Feeding may be commenced gradually.

The Hardy Fruit Garden.

Supports for Bushes.—Gooseberry and Currant bushes often get out of position and heel over. Where such a state of things exists, a sufficient number of forked stakes about eighteen inches in length should be prepared. The soil round the stem of the bush to be operated on should then be slackened with a fork, the bush placed in an erect position, and supported by the forked stake placed at an angle with one end pushed a little way into the ground. A piece of canvas should be placed in the fork to prevent friction.

The Vegetable Garden.

Rhubarb.—Growth will soon be active, and, as many things will claim attention soon, the Rhubarb quarters should now be forked over. The principal part of manuring the crop should have been attended to in the autumn by the application of a good top-dressing of farmyard manure. If this was omitted, however, it should now be remedied. In addition to this, a liberal dressing of soot should be given prior to forking over the ground.

Celery.—A pinch of seed should now be sown in a little heat for early use. White is superior to red, and at this period white only should be used. After long experience I can heartily recommend Wright's Grove White.

Spinach.—Autumn-sown Spinach will now be beginning to move, and will be benefited by a dressing of nitrate of soda or fowl-manure. The Dutch hoe should also be run between the lines to aerate the soil. It is well to bear in mind in this connection that dressings of nitrogenous substances are most beneficial in the early part of the season before the temperature has risen sufficiently to permit of the nitrification of the soil by natural processes.

Stored Roots.—If mild weather prevails, stored roots, such as Beet, Parsnips and Swedes, are apt to show growth and, consequently, become stringy. This is especially the case if a little sand or soil has been mixed with them. If they are gone over, decayed roots removed, and returned to their position, growth will for a time be arrested.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mans, Millthorpe.

CULTURAL HINTS ON NEW AND RARE PLANTS.

TREES AND SHRUBS.

(Continued from page 87.)

Rhododendron lutescens, a yellow-flowered species, growing to a height of 8 feet or 10 feet in China, succeeds in this country in a rather sheltered position in cool and moist soil free from lime. The necessity for placing it in a position sheltered from the early morning sun is noticeable in spring, for it starts into growth rather early and the young shoots are liable to injury by frost, especially if bright sun strikes them before the frost has disappeared.

Rubus bilorus quinqueflorus is a strong-growing Bramble suitable for the wild garden. Its chief attraction lies in its vigorous stems, which are covered with a white or glaucous bloom. The best results are obtained by planting in rich loamy soil, and by removing the old shoots each year when the young ones are 1 foot or 2 feet high. Increase by seeds or by bending the points of the branches over to the ground and covering them with soil, when roots and young shoots will be formed.

Ilex Pernyi.—This new Chinese Holly gives promise of becoming an exceptionally good tree for planting as a specimen evergreen, while when common enough it will doubtless make a good hedge plant. Planted in well-drained ground of a loamy character it makes rapid progress, growing into a shapely specimen with little or no pruning. Cuttings inserted in sandy soil in a close frame during July root as easily as those of the common Holly, while it may also be grown from seed. It is quite hardy.

Cæsalpinia Gilliesii is one of the few South American woody plants that may be grown out of doors in the warmer parts of this country. A very rare plant, its interest centres in its delicately-divided pinnate leaves and large inflorescences of golden flowers with bunches of bright red stamens. It should be given a position against a warm wall with a south or south-west aspect, and other necessities are well-drained loamy soil and protection for the base of the trunk in the event of frost.

Picea breweriana.—This Californian Spruce is certainly one of the rarest trees under cultivation, not only in this but in other countries. Found in inaccessible parts of the Siskiyou Mountains, it has only appeared in our gardens within the last fifteen years. A specimen about four and a-half feet high may be seen near the Pagoda at Kew, growing amid Ericas and other shrubs where the soil is sand with a little peat. The healthy appearance of the plant points to those conditions being suitable for its growth.

Sophora viciifolia, though introduced less than twenty years ago, has made many friends by reason of its pretty white, violet-tinted flowers, which appear in profusion during late May and June. At home in light, loamy soil, it succeeds admirably in an exposed position on the lawn, as a wall plant, or in a shrubbery. Cuttings inserted in pots of sandy soil in July root well, while it is easily raised from seed. As it dislikes root disturbance, the plants should be placed in permanent situations while small.

(To be continued.)

HOW TO GROW HOLLY-HOCKS.

THERE are many who are deterred from growing these grand plants by the prevalence of the disease, or, more properly, the fungoid pest, that is likely to infest them, the same pest attacking more or less all the members of the Mallow family, of which the Hollyhocks are the most important of the garden representatives. But one may say that Hollyhocks are indispensable in the late summer and autumn, and they cannot be let go lightly. In strong soils they are nearly always healthy, a plant lasting for several years, throwing up several grand spikes and being well clothed with foliage to the ground. The difficulty arises in the lighter soils, for the Hollyhock is what gardeners call a gross feeder, rejoicing in a soil either of loam or lime, in any case rich and deep and also well manured. There can hardly be a place whose conditions are worse for Hollyhocks than the present writer's garden on a sandy upland, which naturally produces only Heath and Gorse. Here all flower-borders have to be artificially made; but where Hollyhocks are to grow it is made deeper still, the sand taken out to a depth of 3 feet and the place filled with the best stuff we can get together, with the ashes of the fire-heap plentifully admixed and some good manure from 1 foot to 18 inches down. It is true that the plants always lose their lower leaves and are not free from the disease (*Puccinia malvacea*); but as they are necessarily near the back of the border, it is a simple matter to make sure that some group of plants, of close habit or strong foliage, shall be just in front. The well-led Hollyhocks will send up fine spikes and the defect of bareness of the lower stem will not be apparent. The flowers will be so good that their absence would be a grievous loss to the garden, although they must not be expected to be so vigorous as they would be on a soil of a stronger nature. The pest can be kept in check, though not absolutely abolished, by frequent syringing with a weak solution of permanganate of potash as soon as the leaves have made some growth, or with any of the anti-fungoid preparations.

For flowering the same year, Hollyhock seed may be sown in heat as early as the first days of January; but it may be sown a month or six weeks later if the plants are pushed on as quickly as may be. There is a good deal in getting a strain of seed that will give the right-shaped flower. The florists' Hollyhock, so tully double that the whole flower is the same rounded shape all over and is equally tightly packed with crowded petals, is not the best for the garden; in fact, instead of being a beautiful flower it is rather an ugly thing. The best kind has a distinct guard petal or outer petticoat, and the rising centre is only moderately filled. In this case the colour also is much enhanced by the play and transmitted glow of light and tint within and between the inner petals. All this is lost in the round, tight flower, where the light can only play upon the outer surface.

There is much beauty of tender colouring among some of the single Hollyhocks, but of these the ones that are easiest to grow and are the most generally useful are the varieties of *Althæa hibernica*, the Fig-like shape of the leaf accounting for the specific name. The best are those of sulphur and white colourings, which should be secured if possible, or then will probably be a preponderance of

flowers of a poor, washy, purplish pink. But if mixed seed is sown, some will be sure to be yellow and white, and seed for further use can be kept from these.

G. JERYLL.

ACETYLENE GAS GENERATOR REFUSE FOR GARDEN CROPS.

(In Answer to Several Correspondents.)

THE question of the usefulness or otherwise in gardens of the refuse from the acetylene generator plants is very frequently raised, and, in response to numerous requests from readers, we give the following particulars which we published several years ago. Calcium carbide is made by causing lime and carbon to combine together in an electric furnace, so that a compound having the chemical formula CaC_2 is formed. When water is brought into contact with this substance, certain chemical reactions immediately take place, with the result that acetylene gas is generated and a white substance remains mixed and partly dissolved in water. This is shown by the following chemical equation:

The white substance is slaked lime, and if it were not for the presence of some impurities, derived mostly from the form of carbon used in the manufacture of the carbide (that have, of course, been ignored in the equation), this slaked lime would not differ in the least from that obtained when fresh burnt lime is slaked with water.

On account of the presence of some impurities in the carbide, however, the refuse is likely to contain certain compounds of sulphur and lime (sulphides), and occasionally some phosphide of lime, a compound of phosphorus and lime. Both of these compounds are injurious to plant-life, but the latter is not likely to be present in sufficient quantities to do any appreciable damage, and the former soon alter in composition in the soil and become innocuous. Thus the refuse may be used with advantage upon soils, though it should first be exposed to the action of the air for a time before it is allowed to come in contact with roots. It may be spread on the soil in the autumn at the rate of about half a bushel to the square rod, as evenly as possible, and allowed to lie for a time before it is forked in. Used in this way it will have the same beneficial effects upon the soil as a dressing of slaked lime applied in the same way, counteracting sourness of the soil and mitigating the evils arising therefrom, and, in the case of clay soils, causing the minute particles of clay to coagulate and therefore making the pores in the soil larger and the soil itself easier to work, more open to the air and, as a result, more easily warmed by the sun in the spring.

SCIENTIST

LILIES OF THE VALLEY.

LIFTING AND REPLANTING OLD CROWNS.

LILIES OF THE VALLEY are often planted in the borders and then left there untouched for many years, with the result that the spikes of flowers become fewer each year and hundreds of crowns fail to flower at all. When growing in the woods in a natural state, these Lilies get an annual top-dressing in the form of decaying leaves and other matter; but it is only a light covering, and not a heavy one such as is often put on by the inexperienced cultivator. I have seen plants ruined

through injudicious surface mulching. It is not a wise plan to disturb the plants too often. When well planted in good soil, they will continue to grow strongly and flower freely for a number of years. I have grown half an acre of Lilies of the Valley in various parts of a garden where the soil also varied, some being light and a portion clayey, and always found the crowns to do well when not overcrowded. The overcrowding is often caused by the great number of small crowns being mixed with the large ones. An unprofitable bed should be dug up, the crowns of the plants assorted and replanted in deeply-dug soil made moderately firm. This work may be done at once. Directly all the leaves can be cleared away without forcible pulling, lift the crowns and at once pick out the strongest, keeping both roots and crowns moist. There is nothing better for this purpose than damp sand, as it also excludes air.

Only trim off any bruised roots, and replant the best crowns 9 inches apart in rows 1 foot asunder. This is not too far apart to plant where it is intended that the bed should remain undisturbed for a number of years, as the roots soon spread and the big leaves entirely hide the soil. The weaker crowns should also be planted, if the stock is limited, in another border, allowing space in proportion between them. In two years' time these secondary crowns will have yielded strong ones, bearing big flowers on stout stems. An annual top-dressing of sifted leaf-soil is highly beneficial in the case of all the beds. One often sees the roots actually bared through the raking off of rubbish in the autumn, and when no effort is made to cover them, the crowns degenerate rapidly. Some cultivators believe that Lilies of the Valley can only be successfully grown in certain positions, but I have proved that they will succeed in any aspect if treated as suggested above. Avon.

THE FRUIT GARDEN.

WOUNDS ON FRUIT TREES: THEIR DANGER AND PREVENTION.

IN the social and political realm of life the aged are apt to regard the past with feelings of regret, and to talk and write of the good old days. So those of us who have had a considerable experience of fruit-growing are inclined to look back and regret the days that are past, when, at least so we think, it was an easier task, and the difficulties that we encountered were not so numerous nor so hard to overcome as they are now. In no direction is this so striking as in the increasing virulence of the fungi that attack the wounds of trees. Despite all that has been written and said during the last twenty years concerning canker, the ravages due to the fungus that causes it, *Nectria ditissima*, are in no way abated; while the last decade has witnessed terrible strides made by that awful scourge, silver-leaf disease, due to the fungus *Stereum purpureum*. Since there is no doubt at all that the latter invariably first obtains an entrance into the tissues of the tree through a wound, and moreover, it is pretty well established that the majority of cases of canker are started in the same manner, it becomes a question of paramount importance, first, to reduce the chance of wounds, accidental and otherwise, on a tree to a minimum, and, secondly, to so protect such wounds which may be made that the fungus spores may not find an entrance thereon.

In a strict scientific sense, a wound is any breaking or abrasion of the surface tissue which is unprotected by palisade cells, or callus. There are many wounds which can be prevented, and as things are at present, must be prevented if the trees are to be kept in a healthy state. There are the wounds too often, alas! caused in staking the trees soon after they have been planted. Too many people allow the stake to project into the head of the tree, so that the boughs chafe on it when moved about by the wind, and a wound soon results. Then, again, even if the trees are properly staked at first, they sometimes break or something else happens that the tree breaks loose; then, if it is not soon seen to, the inevitable result is that it is dashed against the stake and injured. In the case, too, where no staking is done at all, after a little while the tree gets loose at the top of the ground, and when a spell of frost comes and makes the surface soil hard, the bark of the tree is soon chafed sore in rubbing against it. Again, in orchards or plantations where cultivation is done by horse labour, unless the ploughman is specially cautioned against it, he will get too close to the trees and allow either the horses' harness or the draw-bar of his plough to break the bark of the trees in many places. A further fruitful source of wounds in trees, and wounds, moreover, which are extremely slow to heal, is the practice of shooting among them, either for pleasure or in order to kill birds or vermin which are causing damage. Wounds, too, are caused in various ways when the fruit is on the trees, either by allowing the branches to break owing to lack of support when heavily loaded with fruit, by carelessness in placing the picking ladders, so that the greatest weight is put upon the tree instead of on the foot of the ladder, or, when the trees are large, by scrambling about in the branches in boots shod with heavy nails.

So much for preventable wounds, but there are others, those caused by pruning, which must of necessity be made for the well-being of the tree. The problem, therefore, is to provide the best means of protecting these wounds, either naturally or artificially. An examination of a wound of a few months' standing, say, where a bough has been removed, will show that Nature is hard at work trying to protect the wound, and that a layer of new tissue is creeping over it from the bark inwards in the effort to cover it up. No growth at all takes place from the wood, only from the inner bark; consequently, if the wound is a large one, it is a matter of considerable time, even years, before the new tissue finally creeps all over and the wound is entirely covered up. What we require to do is, first, to make it as easy as possible for the healing process which the tree itself carries out; and, secondly, so to protect the larger wounds that no fungus spores may obtain an entrance during the interval before the wound is finally protected by new bark.

Good pruners have always insisted on any saw cuts—that is, where branches have been removed by a saw—being shaved with a knife all round the bark and a small portion of the wood adjoining, believing that the bark healed over more quickly when this was done. Perhaps, as with the old notions in connection with planting, the people at Woburn will prove that all such care is a waste of time; but at present it will certainly be advisable for all pruners to adopt the practice, and, moreover, do their work as far as possible with a good sharp knife, without having recourse to secateurs or other mechanical aid,

since, after all, there is nothing which makes such a clean cut as a good pruning-knife.

Protecting Wounds.—With regard to the protection of the wound, after considerable investigation and some amount of trial I have come to the conclusion that the course advised by Professor Bailey in America is the best, viz., to paint the wounds with either red or white lead paint. This should be made with pure linseed oil free from adulteration, and preferably without the addition of turpentine. I have found that paint made thus will set quite hard, and will not flake off the wounds when growth takes place during the following summer. On one occasion I used red oxide paint, mixed for painting ironwork, in mistake for the red lead; but no ill-results followed, and we found, indeed, that this set harder than any of the others. Stockholm tar can be used, but it is necessary to see that it is pure, otherwise harmful results may ensue; but gas-tar should, in my opinion, never on any account be used, even on the largest or oldest trees. It is always a matter of uncertainty how it will behave and whether it will cause injury, and I cannot see any necessity for running the risk, as one has excellent materials in the paints just mentioned. For the last two or three years now I have used such paints, with quite good results, and have found that they have little or no retarding effect upon the self-healing process of the tree, the bark creeping over the wound much as if there were no paint there. To sum up, avoid as far as possible making any unnecessary wounds on the trees; in pruning make the cuts as clean as possible, so as to assist the tree to heal them; and, lastly, protect all wounds from 1 inch in diameter upwards with either white or red lead paint as pure as possible, but without the admixture of turpentine.

F. HAMMOND.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

TROPÆOLUM SPECIOSUM (J. K.).—Your better way would be to purchase roots and plant them near a wall, or in some north-western exposure where the plants could ramble amid Holly or hick bushes. The plants appear to prefer a sandy soil with much fine leaf-soil incorporated therewith, the whole being made moderately rich. Cover the roots not deeper than 2 inches with the soil. The fleshy roots now obtainable may be had very cheap from most of the hardy plantsmen. Seedlings may take two years and even longer before flowering.

PLANTS FOR A LONG BORDER (Constant Reader).—Either of the following subjects would do for your centric bed between the two red Geraniums: *Calcœolaria Golden Gem*, white *Geranium Queen of Denmark*, or *Marguerite* Mrs. F. K. Sander. The same *Marguerite* would do very well for your window-boxes; some of the most successful window-boxes noted last year were composed principally of that plant. Sweet Peas would be likely to thrive in the tubs you mention, or you could plant climbing *Nasturtiums* in them. It would not be wise to plant anything between your rows of *Antirrhinums* and *Godetias*, but you might plant white Stocks in front and a row of *Fairy Queen Begonia* if you think there will be room.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Office: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Cucumbers from South Africa.—An attempt has recently been made to ship Cucumbers from Cape Colony, the first consignment arriving at Covent Garden Market early last week. These were sent over with a shipment of fruits, but when they reached the market were quite unfit for use. Evidently different treatment to that required by Cape fruits is needed if Cucumbers are to reach us from there in good condition.

An Early Rhododendron.—The present winter has been unusually favourable for the early-flowering Rhododendrons. In the Rhododendron Dell at Kew there is a large bush, 9 feet in height, of the variety George Cunningham, well clothed with trusses of blooms. This variety is a fitting companion for Noble's Rhododendron (R. noble-annua), which also is flowering freely close by. The variety George Cunningham was raised, many years ago, in the nurseries of Messrs. Cunningham, Fraser and Co., Comely Bank, Edinburgh. The trusses of flowers are moderate in size; the individual blooms, rather closely arranged, are white, liberally spotted or blotched with chocolate-coloured markings.

Pruning Lilacs in London.—Those who have visited the Victoria Embankment Gardens during the last week or two have had an opportunity of seeing how not to prune Lilacs. The thin, weedy-looking shrubs that border the roadway are mostly Lilacs, and just recently they have undergone a process of thinning that is quite remarkable in its way, and entirely opposed to good gardening. A few lessons in the pruning of shrubs of any kind are sorely needed by those who have been doing the work. Lilacs are, even if properly treated, quite unsuited for these gardens, and they should long ago have been replaced by more suitable shrubs. But as they still remain, it is difficult to understand why they should be mutilated in this way and made to look even more incongruous than they were wont to do.

Sweet-Scented Annuals.—The note on the Night-scented Stock which appeared last week has brought requests from several readers for the names of other annuals that possess this precious attribute in marked degree. In addition to the well-known Mignonette and Ten-week Stock, we have pleasant memories of the fragrance of Nicotiana affinis, or Sweet-scented Tobacco, Martynia fragrans (a rather tender plant), Sweet Sultans, Woodruff, Indian and Japanese Pinks, Schizopetalon Walkeri, Candytuft and, of course, the ubiquitous Sweet Pea. An annual that is not usually credited with fragrance is the common Tropaeolum, or Nasturtium. Its perfume is not at all pronounced, but a vase of flowers shut up in a room for a few hours will emit a perfume that is, in contrast to that of many flowers, quite refreshing. How many of our readers have noticed this?

Royal Agricultural Society's Horticultural Exhibition.—The Royal Agricultural Society of England is sending out a very attractive schedule of prizes to be competed for in the horticultural section of their annual show. This year the show will be held at Bristol, the horticultural section opening on July 1 and closing on July 4. Entries should be sent to Mr. Peter Blair, Trentham Gardens, Stoke-on-Trent, on or before May 31.

A Good Winter Green.—Although green food has been plentiful this winter, thanks to the mild weather, it is not always so, and it may be useful to draw attention to one variety that is in season just now. This is Russian Kale, or Chou de Russie. It is a hardy, elegant-looking plant, the much-lacerated leaves having quite a unique appearance. Seed should be ordered now for sowing towards the end of April, the young plants being transplanted to firm ground when large enough. A bed of this Kale will give an abundance of fresh, delicious young shoots at this season, when there is usually a scarcity of most kinds.

Winners of Acrostic Prizes.—In the list of prize-winners published on page 91 of last week's issue, we regret that a mistake occurred. On investigation we find that the Rev. J. E. Gardner of Eversden Rectory, Cambridge, who sent in solutions under the pseudonym of "Nemo," correctly solved Nos. 1, 4, 6 and 7, and is therefore entitled to share the first, second and third prizes with Mrs. Macalister and Mr. R. P. Brotherston. Under the circumstances we shall also divide an amount equal to the third prize between the other competitors whose names and addresses we published last week.

Primulas at Clendon Park.—Passing through this beautiful Surrey park quite recently, we observed a little copse, in which Primula denticulata and its improved form, cashmiriana, with rich violet purple blooms, were flowering to perfection. A wooded dell on heavy soil, in which tree growth is not too dense, is obviously an ideal home for Primulas, and quite near to this spot may be seen the wild Primrose growing naturally. The beauty of the scene is all the more appreciated, as a public footpath runs through the wood. Many other Primulas are naturalised in the woodland at Clendon Park, but Primula denticulata cashmiriana, which is becoming more and more popular, is worthy of special note.

The Pavilion at Kew Burned Down.—Readers in all parts of the world, and Kew men in particular, will learn with regret that the tea pavilion, which stood near the Pagoda in the Royal Gardens, Kew, was burned down in the early hours of February 20. The pavilion was built about twenty-five years ago and was of rustic appearance, so as to be as far as possible in harmony with the sylvan surroundings. A card found near the conflagration was signed "Two Voteless Women," and we understand that two women are in custody charged with the offence. Such wanton acts of mischief call for no comment.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Rose General G. R. Horne.—I cannot trace this Rose in the growers' catalogues that I have before me. I have been promised by a friend some buds of this for budding next season, and he tells me that he had two plants sent to him along with others by a grower, whose name he has, unfortunately, forgotten. I should be glad, therefore, if you or some of your readers could give me information about it. From what I saw of the plants, the Rose appears to be a strong grower.—B. A. BELL, *South Norwood*. [We know of no Rose bearing the above name. Perhaps some reader will kindly let us know if such a variety is in cultivation.—ED.]

Diascia Barberæ as a Perennial.—I constantly see in various seedsmen's catalogues this plant in the list of annuals; but in this garden, which

Apple Lane's Prince Albert for Dessert.—The reference to this variety in "Notes of the Week," issue February 15, is very timely. I have always had a strong liking for this Apple, it being a grand all-round variety. At this time and as late as the early part of May I used it as a dessert variety, and it was greatly appreciated. In March and April my fruits used to assume a deep yellow tinge on one side, and while in that condition were most acceptable for dessert. Amateurs should always include a few bushes in their collections, but they should not allow the trees to bear much fruit until they are well established. Many specimens are stunted through premature cropping.—G. G.

Hardiness of Campanula isophylla.—Whether this plant is hardy or not is very much a question of locality, though more particularly of the position individual examples occupy. For instance, in the drier conditions the wall garden affords, in the deep-running crevices of the rock garden, or in window-boxes—almost anywhere, indeed, where it would be raised above the ordinary level, and

Lilium Brownii leucanthum.—The fine group of this Lily shown on page 94 of the last issue is, unfortunately, described as *L. Brownii*, omitting the varietal name. The photograph was taken at Kew in 1905 from a group of bulbs bought in 1904 from Messrs. Veitch and Sons as *L. Brownii leucanthum*. This is the Lily that Wilson describes as *L. Sargentiae*. It is a taller plant than the typical *L. Brownii* and resembles *L. sulphureum* somewhat, both in the yellow tint of the outside of the flowers and in its habit of producing bulbils in the axils of the leaves.—E. A. BOWLES.

Serious Losses Among Roses.—I note in THE GARDEN of February 8, page 66, Mr. C. Blair's remarks on Roses at Preston House Gardens and the damage done by the frost in November of last year. In the gardens here and the surrounding district the majority of climbers are killed to the ground, while dwarf Roses, with the exception of the Lyon, have suffered less. On a pergola built of stone pillars and Oak beams some of the varieties have escaped injury, viz., Leuchstern, Rubin, Félicité Perpétue, Bennett's Seedling, while American Pillar, Gardenia, Dorothy Perkins, Lady Gay and many others are completely spoilt.—C. L. CAWKELL, *The Gardens, Angerton, Morpeth, Northumberland*.

Mysterious Disease of Hyacinths.—I was greatly interested to see in THE GARDEN of last week Mr. J. Duncan Pearson's comment on the mysterious disease of Hyacinths and Daffodils, as it has revealed to us the cause of our Roman Hyacinths failing this season. Out of our whole batch none of them made any roots worth speaking of, and those they did soon decayed. The bulbs were potted up in September and plunged in ashes, and on examining them in November were found to have made about one inch of top growth, and the roots which they had made were all decayed; yet the bulbs in themselves seemed quite good. We were quite puzzled as to the cause, because all our Narcissi and the named varieties of Hyacinths have come through all right and have bloomed splendidly. Naturally, we put it down to bad bulbs, and drew the nurseryman's attention to it. His remark was that his bulbs were just the same, and he could not account for it.—F. C. WILLIE, *Lindfield, Sussex*.

Puya chilensis Flowering at Cambridge.—This handsome Bromeliad, which for some time has been an attractive feature in an outside border in front of the plant-houses at the Botanic Gardens, Cambridge, and is said to be only equalled in the Scilly Isles, is now coming into bloom. The spike was first noticed on February 5, when it had forced its way through the glass light which is placed over it in the winter, being at that time 20 inches high, and has since grown at the rate of about three inches a week. It is 12 inches in circumference 10 inches from the tip, that being larger, and has every appearance of bearing a fine inflorescence, probably fully developed about May or June. The plant is 6½ feet high and about seven and a-half feet through, and has been growing outside now for some years, but, as previously mentioned, covered with a glass light in the winter, while in very severe weather mats are hung in front of it. The leaves are from 3 feet to 4 feet long, with hard, hooked spines on the margin. Up till 1910 the plant was one huge rosette; then it commenced to send out branches, which one would expect to come after, not before, flowering, unless the spike has been forming for some considerable time.—F. G. PRESTON.

THE NEW WHITE BEDDING CROCUS KATHLEEN PARLOW.

is in by no means a specially warm situation, it has proved itself a perennial, flowering abundantly during the late summer and autumn from a seed planted seven years ago. It increases from underground roots, and is now a patch 3 feet by 2 feet 6 inches, or thereabouts. The flowers are shaped like a miniature spurred *Aquilegia*, and are of a pretty shade of copper colour.—V. M., *East Devon*. [Our correspondent's experience of this pretty South African plant is interesting and valuable, proving that, given certain conditions, it is of strictly perennial duration. Seven years is surely ample time, and the development of the plant to a patch 3 feet across is conclusive. We trust the above letter will tempt others living in favoured places to regard it as a perennial. Generally, however, the plant has to be regarded as an annual as a matter of convenience. Other South African plants of our acquaintance do not die as a result of flowering and seeding, but perish because they cannot endure the cold and vicissitudes of our English climate.—ED.]

therefore well drained and warm—the plant may be regarded as generally hardy, unless in very severe winters. If, however, the plant is colonised in the soil of the rock garden or grouped in the border in the ordinary way, it will perish before the winter is half gone, even around London. At the same time, it should be stated that it is not suitable for the border. The right place for a plant with its mantling habit of growth is the higher parts of the rock garden, where its free and late flowering would render it unique. In a window-box or hanging basket or pot much of the beauty of the plant is revealed, but in so cultivating it its value to the rock garden has been almost entirely overlooked. For this latter purpose we have nothing so good or so late flowering, and plants which give such sheets of colour are worth making much of. My hybrid *Campanula Pro-tusion* has *isophylla* blood in its veins, and the same conditions in wall or rock garden suit it exactly. In garden soil it is not reliably hardy, and, moreover, is not suited thereto.—E. H. JENKINS.

Delphinium (Larkspur) - white flowers, and leaves

Peas During 1912.—Although last year was not a particularly good one, all our culinary Peas did admirably. Perhaps some readers of THE GARDEN may like to learn of our method of cultivation. We dig or trench the ground in winter in the ordinary way after it has been well manured. As the time for sowing approaches, we dig trenches as for Celery and 8 feet apart, and dig in a good lot of farmyard manure. The Peas are sown thickly in the trenches, and it is very rarely they require watering. Our chief varieties last year were Little Marvel, Advancer, Alderman, Essex Star, Model Telephone and Victoria. I am very reluctant to trust new varieties for main crops, hence the old varieties. From two quarts of Essex Star sown we gathered upwards of twelve bushels of pods. All other kinds did well in a lesser degree.—JOHN BEAMS, *Kensington and Chelsea School, Banstead, Surrey.*

Rose Rayon d'Or.—Your correspondent, Mr. H. E. Molyneux, on page 81, issue February 15, groups this Rose with the Hybrid Teas, but I contend it is so very distinct from that tribe that its inclusion among the Hybrid Teas would be an error. One has only to look upon its lovely foliage and prickly growths to see at once that it belongs to a new race; and why not call this race *Rosa pernetiana*, as most authorities are doing? I am as much averse as anyone to multiplying groups; but when a new race is so very evident, as in the case of Roses such as Arthur R. Goodwin, Rayon d'Or, Juliet and Beauté de Lyon, to say nothing of the beautiful varieties M. Pernet-Ducher will soon be sending us, I think it is quite time for our National Society to recognise the group. I admit there are already two sections of this new group, the one more closely resembling the sturdy Soleil d'Or and the other the Hybrid Tea; but I am convinced all thoughtful rosarians will see the wisdom of recognising the new group.—DANECROFT. [We notice that some of our leading Rose nurserymen are listing Rayon d'Or as a Hybrid Tea, but it is, as our correspondent points out, one of a quite distinct type.—ED.]

The Multiplication of Sweet Pea Names.—Your correspondent "Amæthon," page 60, February 1 issue, waxes eloquent on this subject, and, like me, he wants something done. The question is, "What?" My latest suggestion is that two lists should be compiled, one of synonyms and one of too-much-alikes. Of the latter, no two, under existing rules, should be shown in one exhibit; of the former, all the varieties in any one class, e.g., crimson, cream, and lavender, must be exhibited under one name chosen by the floral committee of the National Sweet Pea Society. Decorator, which received an award this year, is a step in the right direction. But the question is not so easy as it looks. If it were a question of colour only, it would be easy enough; but there are other things to consider. "Amæthon" seems to think that none but a committee of amateurs can give a reliable and unbiased decision on the question. Why is this? If such men as Cuthbertson, Sydenham, Wright and many more cannot be trusted to decide on merit only, who can? I might add the names of Aldersey and several others. For myself, as a member of what may be called the "amateur" class who, being obliged to earn his living, has taken up Sweet Pea culture with that object and from an unborn love of flowers, I may say that I have complete confidence in the official members of the National Sweet Pea Society. I believe that they are honestly desirous of giving a fair and just decision on all matters

that are brought up for their consideration, and for this reason probably hesitate to "rush in where angels fear to tread" theoretically. I would rather see these questions decided by a committee of amateurs; practically, they would probably be a hopeless failure.—T. H. DIPNALL.

Three Good Hyacinths.—Somehow, I cannot quite give them up. Old associations are very clinging. Last autumn I bought one or two "pigs in a poke"; one of them, Oranjboven, is very charming and of an uncommon colour among Hyacinths. My Dutch dictionary tells me that the name means extra or very orange, and so it is. There is a deeper hue down the middle of each petal, with the edges much paler. I have consulted my Colour Chart, and found the dark stripe to be 761 and the lighter outsides 751 or thereabouts. The bells are not too crowded on the spike. A well-tried old friend is the pretty pale pink General de Wet. I like the curl back of the petals and the loose arrangement of the flowers on the stem. Sir William Mansfield has been a stranger for a considerable time, but I have renewed his acquaintance this year. The colour is a reddish mauve, and the type of flower and spike rather recalls Gigantea. It is just a wee bit weak on the stem, and needs a friendly support. "Quite a lady's shade," I was told yesterday.—J. JACOB.

Sweet Peas as Bedding Plants.—I was greatly interested in reading the article under this heading in THE GARDEN for February 1, page 56, as I have used the Sweet Pea for beds since 1902. During that year the bed was a large Maltese cross, and the colours used were red, white and blue. The centre was red, and the arms were white and blue alternately. When the planting was completed, a wire frame the exact size and shape and covered with netting was placed over the bed. As the plants advanced in growth they were taken through the netting (which was about six inches above the soil) and trained within their allotted space. The training, pinching, tying and pod-picking required great attention; but when the plants were in full bloom the effect was charming. For convenience of training and tying, a four-legged stool or form was thrown across the centre of the bed; then a broad plank was stretched from the grass to the stool, from which plank any part of the bed could be reached with ease.—J. BROWN, *Balminnoch, N.B.*

Applying Manure-Water to Roses in February.—I was much surprised to read Mr. T. Stevenson, in "Gardening of the Week" of the issue February 8, recommending the above practice. During a fairly long experience I have never seen nor known manure-water given at this time of the year, nor can I recall to mind having seen it advised by other writers. True, it is carried out in late autumn, and even early winter when mild, for fruit and Rose trees; but can it be wise to give manure-water just now? To the writer it seems more likely to be injurious than in any degree beneficial, but I may be wrong in so judging and am open to correction. Most rosarians, I feel sure, are anxious just now that their plants should remain as quiet as possible; but manure-water is always admitted to have an exciting or stimulating effect upon growth. There is another month of dangerous weather possibilities, and, owing to the mild weather we have had, Roses are already too much advanced for the time of year. Is there any proof that Rose trees in their present stage of growth need or can avail themselves of manure-water, or that the soil will retain it until they stand in need?—C. TURNER.

PRIZES FOR THE BEST ROCK GARDENS.

To further stimulate the interest that is being taken in rock gardens, the Proprietors of THE GARDEN offer the following prizes for three photographs of a rock garden, or portions of a rock garden:

First Prize: Five Guineas, or a Silver Cup of that value.

Second prize: Two Guineas, or Books of that value.

Third prize: One Guinea.

The competition is open only to the actual owner of the rock garden, or to his or her gardener. The object is to encourage good rock gardening, and preference will, therefore, be given to those rock gardens which show originality in design, and where the plants depicted are well grown. It should be distinctly understood that awards will be made to the best rock gardens, and not necessarily to the best photographs. The photographs need not be taken by the competitor, who must, however, in such cases have the written consent of the photographer for their reproduction in THE GARDEN. The competition is subject to the following rules:

1. Not more than three photographs of each garden may be sent in by one competitor.
2. Each photograph must have the full name and address of the competitor plainly written on the back in ink.
3. Successful competitors shall furnish written particulars of the rock garden forming the subject of their photographs.
4. Glazed P.O.P. prints must be sent, and each should be on a mount with not more than half an inch margin.
5. All photographs must be sent to arrive at THE GARDEN Offices, 20, Tavistock Street, Strand, W.C., not later than June 1, 1913.
6. Unsuccessful photographs sent in for competition will be returned if a sufficiently stamped and addressed envelope or wrapper is enclosed for the purpose, but no responsibility will be taken for the loss or damage of photographs submitted, although every care will be taken to return them uninjured.
7. The Proprietors of THE GARDEN reserve to themselves the right to reproduce any photograph sent in for competition.
8. The decision of the Editor will be final.

CROCUS KATHLEEN PARLOW.

This new Crocus is an exceptionally bold-looking and handsome bedding variety with pure white flowers. The plant is a very free bloomer. It was exhibited by Messrs. Cartwright and Goodwin of Kidderminster at the last fortnightly exhibition of the Royal Horticultural Society, when it was the only novelty brought before the floral committee to receive an award. It was granted an award of merit.

FORTHCOMING EVENTS.

March 4.—Royal Horticultural Society's Meeting and Bulb Show (two days). Lecture at three o'clock on the first day by Mr. W. H. Divers, F.M.H., on "The Spring Flower Garden." Scottish Horticultural Association's Meeting. Croydon and District Horticultural Mutual Improvement Society's Meeting.

March 6.—Linnean Society's Meeting.

THE ROSE GARDEN.

A SIMPLE GARDEN SEAT.

MANY pleasing features of a garden can be made in the simplest way, and the garden seat shown in the accompanying illustration is one of these. The seat itself is of a simple character, constructed of slips of wood about an inch and a-half across and about an inch thick. It is set on posts with a pavement of flat stones underneath and in front, and is covered with an arching bower, composed of branches from an old Ash tree which stood in the field from which the garden was formed, and which had to be cut down for the sake of the garden. These were selected so as to form arches over the seat, and they have been covered over with the lovely Blush Rambler Rose, one of the freest and most vigorous as well as one of the most charming of all Rambler Roses. It makes strong shoots annually, and these, if just shortened and the weak and oldest wood removed, give each year a mass of lovely blush flowers. These are comparatively small and semi-double, and are borne in huge bunches. The illustration, unfortunately, does not show the whole of the flowers.

Dunfrics. S. ARNOTT.

SOME OF THE NEWER ROSES.

TEA ROSES.

(Continued from page 92.)

MANY of the Teas make fine decorative garden plants, especially the more hardy varieties of the family, such as G. Nabonnard, Mrs. Herbert Stevens, Mme. Antoinette Mari, Jean Dupuy and Souv. de Pierre Notting, to name only a few; and in the South and South-West they might with advantage be much more freely planted. A good Tea is the most beautiful Rose we have. There is an additional refinement about the flower that other Roses lack, and the extra trouble that may be necessary for their culture is so slight, taking the form of earthing up during the winter, that one is amply repaid. I have already dealt with the newer exhibition varieties, and the garden or decorative list is not a long one, as few of the hybridists make a speciality of Teas.

Lady Hillingdon (Lowe and Shawyer, 1910).—This, until the appearance of Sunburst, was our deepest yellow garden Rose, and I am not sure that it is not still entitled to that distinction. It has fine long pointed buds of a deep apricot yellow, but the open flower is apt to be thin. A fine Rose on a standard or half-standard, but it hangs its head somewhat, which is its only fault. A good grower, mildew-proof and fragrant. Awarded the gold medal of the National Rose Society.

Little Dorrit (Paul and Son, 1912).—This I described under "Hybrid Teas," to which class I

believe it belongs. It is of China-like growth and a very pretty and promising variety, but it appears to be catalogued as a Tea in most lists.

Miss Alice de Rothschild (A. Dickson and Sons, 1910).—This is a good strong grower, almost Hybrid Tea-like in growth, but with a Maréchal Niel perfume that may or may not denote its parentage. A free-flowering yellow Tea of much promise as a garden Rose, mildew-proof, and makes a fine standard.

Mrs. Foley Hobbs (A. Dickson and Sons, 1910).—Although an exhibition Rose of the first water, this Rose should be in every garden. I consider it the finest Tea of recent introduction, and as it is of easy culture and good growth, good alike on dwarf or standard and sweetly perfumed, all should try

frosts of October, it was one of the last Roses in my garden to give me a good flower.

DWARF POLYANTHAS OR POMPONS.

There have been a fair number of additions to these delightful Roses in the last few years, but I have not grown many of them. Herr Peter Lambert of Trier has given us many varieties. Messrs. Paul and Son of Cheshunt have sent out several, notably their Queen of the Musks and Snowstorm. Then two very fine additions to this class in Maman Turbat (Turbat and Co.), a very pretty flower, large for this class, and Yvonne Rabier (Turbat and Co.), a beautiful white that should be grand for beds, made their appearance at the "International" at Chelsea, and are now in commerce. They should certainly be tried.

Jessie (Merryweather, 1909) must also be mentioned. A bright crimson, small-flowered variety but very free, keeping its colour well and always in bloom. Excellent for a dwarf bedder under standards or as an edging. I have a half-standard that is carrying flowers now (February), notwithstanding wind, rain and hurricane.

Orleans Rose (Levavasseur, 1910)—A fine companion to the above, and, I think, the best of all the numerous pink varieties. I prefer it to Mrs. Cutbush, generally accepted as the best pink. It is freer-flowering in the autumn, and produces its flowers in immense clusters.

Southampton. H. E. MOLYNEUX.

FALLACIES REGARDING TEA ROSES.

IN most of our Rose guides we are instructed to give Tea Roses a light, gritty soil, and the warmest spot we can select for them. As I have no specially warm spot, and as my soil is about as strong a clay as can well be imagined, I was compelled to plant my Tea Roses under these disadvantages. But what do I find? Why! simply that the Roses seem intensely happy under the conditions named. I have such sorts as Mrs. Myles Kennedy, Hugo Roller, W. R. Smith, Molly Sherman Crawford, Anna Olivier and Medea making basal growths as thick as one's little finger. Varieties such as Souvenir de Catherine

Guillot and Mme. de Watteville seem quite happy, and I know from past experience in other parts that they are not the easiest sorts to pull through.

I admit I have the advantage of the sea air about one and a-half miles away, but I think it is the soil. The conclusion I have come to is that the seedling Briar prefers clay, and as we had our Tea Roses on the seedling Briar, it seems reasonable to study rather the stock than the Rose budded upon it. We may know that the wild Briar loves moisture, for do we not often find them luxuriating near a brook?

It is really wonderful what a length a seedling Briar root will descend. I have dug some plants this year whose roots when measured were over a

A SIMPLE GARDEN SEAT. THE ARCH IS COVERED WITH ROSE BLUSH RAMBLER.

it who have not done so. A gold medal variety. Colour, delicate cream; the catalogues call it ivory white. The young flowers have a slight Picotee edging that adds to their charm.

Mrs. Herbert Stevens (S. McGredy and Son, 1910).—Another Rose I referred to under "Exhibition Varieties," but its right place is among the garden Roses. A pure white Rose of long pointed flowers, of not many petals, that hangs its head modestly; it is a great favourite with me. A vigorous grower for a Tea, as hardy as any Rose. I am inclined to call it the most refined, if not the most beautiful, of all white Roses. A bed of it has flowers from May until December in an ordinary season, and last year (1912), despite the early

yard in length. No wonder such plants can laugh at a dry season when they are so well anchored in a clay subsoil. I thought perhaps this might be a useful topic to discuss at this slack season, and it would be very helpful to beginners in Rose-growing.

DANECROFT.

THE GREENHOUSE.

GREENHOUSE PLANTS FROM SEED.

WITH the advent of spring, seed-sowing, both out of doors and under glass, is in full swing, and among other items the decoration of the greenhouse and conservatory during the summer and autumn months has to be fully considered and provided for. Of course, many of the occupants of these structures are of a permanent character, and others that loom largely as greenhouse flowers, such as Primulas, Calceolarias, Cinerarias and Cyclamens, must not be sown thus early in the year. Still, there are a great many that may be sown now, notably a large variety of annuals, which for greenhouse decoration increase in popularity year by year. One of the reasons of this is that annuals have had a deal of attention devoted to them of late, the result being vastly-improved forms, and also the fact that the different varieties and colours can be depended upon to come true from seed. It is, of course, necessary that the seed be obtained from a reliable firm.

Good Kinds.—Of flowering annuals that are particularly amenable to pot culture may be mentioned *Alonsoas*, *Nemesias*, *Phlox Drummondii*, *Asters*, *Balsams*, *Browallias*, *Coleus pyramidalis*, *Clarkias*, *Mignonette*, *Rhodanthe Manglesi*, *Stocks* and *Schizanthus*. Although some of these do not remain at their best for long, by sowing at intervals a succession may be kept up for a considerable time.

Hints on Sowing.—The golden rule to be observed in sowing annuals, or, in fact, seeds of any kinds, is to take care that they are not sown too thickly, otherwise they are heavily handicapped from the start, being drawn up thin and weak. To obviate this, the young plants should after germination have plenty of light and air, as if once weakened, their natural sturdy character cannot be restored.

As an object-lesson against overcrowding, reference may be made to a charming group of *Nemesias* which was shown last summer at one of the meetings of the Royal Horticultural Society. These, which were in pots $4\frac{1}{2}$ inches and 7 inches in diameter, were perfect little models and masses of bloom. Each pot contained but a single plant. The young plants were stopped twice during their growing period, and in this way they formed ideal little specimens. Of course, they were not allowed to get drawn or stunted at any time. The difference between plants grown in this free and natural manner and others that developed under crowded

conditions was brought forcibly to my mind a week or two after I saw those at the Royal Horticultural Hall, when a large batch that made a fine show of flower was exhibited. At a little distance the display was all that could be desired, but close inspection revealed the fact that each pot contained several weak plants that could not possibly keep up a display for as long a period as those that had been grown singly. Moreover, the mixed tints were less pleasing than those of the plants which had been grown singly.

Hornies against thick seeding are often indulged in, but still it goes on. Perhaps in some respects the seeds-men are to blame in giving us so much for our money. The grand effect often produced by a solitary self-sown annual in the open ground furnishes a good object-lesson as to the possible progress of a plant that has not been coddled in any way.

THE FLOWER GARDEN.

A FLOWER BORDER OF GREY AND BLUE.

HAPPILY, there is no lack of subjects that lend themselves to a blue and grey colour-scheme in the hardy flower border, and few colours blend in such perfect harmony. Of blue flowers, the tall spikes of *Delphiniums* in variety and *Anchusa italica* Dropmore variety are indispensable, while others that readily suggest themselves are *Michaëmas* Daisies, *Lupines*, *Campanulas* in variety, *Phloxes*, Flowers of a Day (*Tradescantia virginica*), not to mention the many blue-flowering annuals, such as *Cornflowers*, *Myosotis*, *Nemophila* and *Nigella*, that may readily be used to fill any vacant spots should they arise.

A BORDER OF GREY FOLIAGE AND FLOWERS IN AUTUMN.

Plants with Ornamental Foliage.—It is not flowering plants alone that are readily raised from seed and can then be used for decorative purposes, as many whose ornamental foliage is their chief claim to recognition can be readily increased in this way. Among these may be included *Amaranthus* of sorts, whose bright-coloured, gracefully-disposed leaves are very effective; *Asparagus* in variety, *Coleus* of sorts, *Eucalyptus globulus* and *E. citrodora*, *Grevillea robusta*, *Kochia trichophylla* (which under the name of the Summer Cypress is very popular both indoors and out), with the different variegated-leaved forms of the Indian Corn (*Zea Mays*).

Of the ornamental-foliaged subjects above alluded to, the *Asparagus*, *Coleus*, *Eucalyptus* and *Grevillea* are plants of a perennial character, though they are readily raised from seeds. The others are of annual duration.

For grey effects one needs to fall back upon foliage plants to a great extent, although there are suitable flowers, such as *Gypsophila* and *Statice elata*, producing drifts of grey in cloud-like effect, as seen in the accompanying illustration. Both *Erigerons* and *Eryngiums* may be used to advantage, and help to make up a late summer border such as this. Among the best of the silver-leaved plants must be mentioned *Cineraria maritima* and *Stachys lanata*, while *Cerastiums* and *Antennarias* are likewise useful.

The subject of the illustration is a feature of the charming gardens at Regal Lodge, Kentford. These gardens are perfect in point of colour and grouping, each feature blending unconsciously with the next without undue formality or any leaning towards overcrowding. Thus at one end of this flower border is situated a paved Lavender walk, which in itself is a study in grey and blue.

H P

A MIXED BORDER IN THE GARDENS AT GARNONS, HEREFORD.

with innumerable patches of dwarf Campanulas, chiefly *C. pulla* and the variety *Miss Willmott*, with bells of silvery blue, growing between the paving-stones.

The grass path in front of the flower border leads from the Lavender walk to a little flight of steps in grass, whence one is conducted to a well-trained pleached alley of Lime trees—a feature that was at one time popular in old-world gardens, but now not seen as frequently as one might hope to see it. The simple design of the trellis-work in the background of the border has much to commend it, and when clothed with blue-flowering Clematises it will enhance the beauty of this simple flower border, where harmony in colour rather than contrast is desired.

SOME HARDY BULBS FOR SPRING PLANTING.

WHILE many bulbs which may be planted in spring, from now until the end of March, are well known, there are a goodly number which are not within the ken of the amateur, and about which he may like to know a little. By their aid his garden would be rendered a pleasure of higher beauty and of more intense interest. Some of these bulbs are not listed by many bulb-dealers, yet all may generally be procured through the specialists who advertise in the pages of *THE GARDEN*. They ordinarily present little difficulty in their cultivation, but it must be noted that a number of them are not suitable for permanent planting and ought to be lifted when the leaves become yellow, dried carefully, stored in dry sand, and kept out of the reach of frost until the following spring. Unless otherwise indicated, they should be planted in an open soil of loam, leaf-soil and sand. A sunny place is preferable, though such flowers as the Poppy Anemone should have a slightly-shaded place.

Anemones. It is unnecessary to describe the Anemones, especially of the coronaria section, of

which the St. Brigid varieties are the best. If planted in March or April from 2½ inches to 3 inches deep, about five inches apart, they will bloom during the summer months, long after the autumn-planted ones are over. The glowing scarlet *A. fulgens* and its varieties may also be planted in spring. *A. apennina*, blue, can also be planted up till the middle of March.

Anomatheca cruenta.—A gem among summer-flowering bulbs is *Anomatheca cruenta*, which has bright crimson-scarlet flowers and is hardy in dry soil in some places, though in many it must be lifted and stored until spring. It is only a few inches high, and does best in a little shade.

Bessera elegans.—Here we have a charming flower about two feet high, with umbels of drooping scarlet blossoms outside, but white inside. Plant 3 inches deep in sandy soil and lift when the leaves die down.

Bravoa geminiflora.—The Twin-flower is a gem among summer-flowering plants, and gives, on stems about eighteen inches high, from twenty to thirty lovely flowers of coral red. It is almost hardy, but should have some winter protection if not lifted in winter. Plant 4 inches deep.

Chlidanthus fragrans.—This is an attractive yellow-flowered bulb, giving white or yellowish, long-tubed flowers in summer. The fragrance of the blooms adds to their attractions. It is nearly hardy, but in cold districts ought to be lifted and kept in sand during winter.

Cooperia.—This, called the Evening Star, is a lovely bulb with white flowers, which only open in the evening. *C. Drummondii* and *C. pedunculata* are the best species, and the latter is the more refined of the two. Plant 3 inches deep and protect in winter if not lifted, which is the safer plan. These have white flowers and are about six inches high.

Crimums.—The hardest of these stand our winters in many parts of the British Isles, and are magnificent flowers for warm places; they give

great umbels of fine flowers on plants 3 feet or so high. The bulbs should be planted a foot deep if to be kept outside, and are best against a wall, with some protection over the border. *C. longiflorum* or *capense* (pink), its variety *album* (white), *C. Moorii* (rosy white, slightly tender), *C. Powellii* (rose), *C. P. album* (white) and *C. yemense* are the best for outdoor culture.

Hardy Cyclamen.—I prefer autumn planting for these, but dry roots of *C. europaeum* (crimson) and *C. neapolitanum* (rosy pink or white), both flowering in autumn, can be obtained. Plant in shade about one inch deep in any soil with some lime rubbish mixed with it.

Habranthus pratensis.—No plant excited more interest at the great show at Chelsea last year than this. It is hardy in the Eastern Counties if grown in sandy soil near a sunny wall in well-drained positions. Plant 9 inches to 12 inches deep. The flowers, of a brilliant scarlet, open in May or June. [Autumn planting is adopted by Mr. Davison of Westwick Gardens, Norwich, who grows the plant better than anyone we know.—ED.]

Galtonia candicans.—Only a reminder that March is the time to plant this grand bulb is necessary. Its pendent white flowers are simply grand in the garden in autumn. Plant 6 inches deep.

Incarvilleas.—These beautiful hardy plants may be planted in the open from February to April. Plant 3 inches deep in good soil. *I. grandiflora* is the dwarfest, *I. brevipes* is the next, and *I. Delavayii* the tallest. The flowers are carmine or crimson, with yellow.

Milla biflora.—This is a charming half-hardy bulb with dainty star-shaped, white flowers. Plant 4 inches deep in sandy soil in a warm place, and lift and dry in autumn.

Pancratiums.—In these we have lovely hardy bulbs, though requiring some protection or lifting for winter in cold districts. *P. illyricum* and *P. martimum* are the best. The former should be planted 9 inches deep, but the latter will do with from 6 inches to 8 inches. The charming white flowers are borne in umbels.

Ranunculuses.—It is necessary to remind amateurs that Ranunculuses may be planted in March or April in good, light, moist soil. Place the tubers about two inches deep, lift when the leaves have withered, and store until autumn or spring. The Giant Double French are the most vigorous.

Tigridias.—Everybody who has a sunny bed or border should grow some of the Tigridias, or Tiger Flowers, gorgeous plants in sunshine, and of almost barbaric beauty. Plant 2 inches deep in a dry, rich bed or border, and when the foliage has withered lift the bulbs and store in dry sand until spring. They are capable of wonderful effect, giving flowers from white through yellows to lilacs, roses and scarlets, and wonderfully marked.

It is unnecessary to speak of Gladioli or Montbretias, as they are frequently treated of in *THE GARDEN*, and Mr. Bowles has been dealing fully with the Lilies.

Dumries.

S. AKSOLF

BORDERS OF ANNUALS AND HERBACEOUS PLANTS.

ALTHOUGH among plants of annual duration only, or those perennials usually grown as annuals, we find some of the most beautiful of our outdoor flowers, one cannot say that they are grown so extensively as their merits deserve. For their beauty alone such kinds as Antirrhinums, Larkspurs, Godetias and Clarkias demand a place in the best of gardens, while the fragrance of such as Mignonette and Night-scented Stock endears them to all. Apart from their beauty and fragrance, however, annuals are particularly useful for filling blank spaces in mixed or herbaceous borders, also for planting or sowing between such bulbs as May-flowering Tulips. These bulbs, owing to their late date of flowering, often cause the gardener considerable worry, as to follow them with ordinary bedding plants would necessitate lifting the bulbs some time before they were ready.

It is in such instances as this that annual flowers have a special value. They can either be sown between the Tulips or other late-flowering bulbs, or plants can be raised in frames and planted out between the Tulips, this latter course being adopted with such kinds as Antirrhinums and Pentstemons, which, though not strictly annuals, are often grown as such, and which must be sown early in the year to get them into flower during late summer and autumn.

The accompanying illustrations—one of a bulb border sown or planted with annuals, and the other a mixed border containing some annuals—are from photographs taken by Mr. J. Croot Tucker in the gardens at Garnons, Hereford, the residence of Sir John Cotterell, Bart. We are indebted to the head-gardener at Garnons, Mr. Charles Liddle, for the following particulars relating to them. Mr. Liddle has only been at Garnons four years, and made up the annual borders three years ago. These borders (shown on this page) are planted with May-flowering Tulips, these being grouped in masses of separate colours, with clusters of German Irises, and the annuals sown or planted between them. Among the annuals used are Antirrhinums, tall white and pink, and intermediate forms of the same colours; Pentstemons—Gosford Pink and Newbury Gem, mauve and pink Verbenas, and white and purple East Lothian Stocks. The annuals commenced to flower at the beginning of July, and made a good display well into the autumn.

The mixed border (page 106) is in front of a fruit wall, and contains Roses on poles, the thornless Rose Zephyrine Drouhin being successfully used in this way. Its vigorous habit, fragrance and the delightful colour of its blooms render it excellent for the purpose. Michaelmas Daisies, Helianthemums, Campanula pyramidalis and Artemisias are freely planted in good-sized groups, with plants of more lowly stature in the foreground.

The illustration on page 108 shows an awkward-shaped bed in an Essex garden, where the same idea of using annuals between bulbs, as referred to above, has been carried out. The bed contains choice Darwin Tulips, between which the Candytutt was sown about the middle of April. As may be seen, the Candytutt is

perfectly happy, and the Tulips were none the worse for the association. The cost of the seed used in this bed was threepence. After the Candytutt had finished, the Tulips were lifted, the ground well dug and the bulbs replanted. Between them Snowdrops were also planted, and these have given a right royal display this spring. Now, the Tulips are coming up freely, and later on will give us their flowers, to be followed in July and August with a display of annuals. In addition to Candytutt and the others already mentioned, there are many annual flowers that could be utilised in this way. A few that come to mind are Mignonette, white Alyssum, Leptosiphon, Virginian Stock, dwarf Larkspurs, Antirrhinums, Nigella Miss Jekyll where tall plants can be accommodated, Godetia, Clarkia and Shirley Poppy.

COLOURED PLATE.

PLATE 1466.

SNAPDRAGONS AND THEIR CULTIVATION.

IN the Snapdragons, or Dragon's Mouths, as we delight to call the many beautiful forms of Antirrhinum majus, we have flowers of great beauty and curious form, plants of excellent habit, free-flowering propensities and almost immune from disease, while their floral display is continued over a longer period than that of most kinds of plants which can be as easily raised from seed. Snapdragons have been known in our gardens for a great many years, and some of the striped forms are figured in the old herbals; but, in common with many other flowers, it is only during the last decade or two that the majority of the beautiful varieties which adorn our gardens have been evolved. These varieties, four of which are shown in the accompanying coloured plate, are the outcome of long, ardent, intelligent labours on the part of a few

of our leading seed firms, among which Messrs. Sutton and Sons have always held a foremost position. It is to this firm that we are indebted for the colour photograph from which the coloured plate has been prepared, and the varieties shown therein are from their trial grounds at Reading.

The usefulness of these modern Snapdragons in the outdoor garden can scarcely be overstated. Providing the soil is well drained and does not contain a great amount of fresh manure, the plants will thrive almost anywhere. Beds or borders may be filled with them, or clusters of one colour may well find a home in the mixed border. For those narrow borders usually to be found next to the dwelling-house, and where the soil is often too poor and dry for many plants, the Snapdragons will thrive luxuriantly, while for the tops of walls, or the interstices of dry walls where there is a modicum of good soil, we know of few better plants. At Hopetoun House Gardens, Linlithgow, particulars of which appeared in our issue for January 11, a whole border of large dimensions is devoted to them, and so well are the beautiful art colours blended that the border is one of the most interesting features of a particularly interesting garden.

Cultural Notes.—Although these Antirrhinums are strictly of perennial duration, the most favoured method is to treat them as annuals or biennials, preferably as annuals. For this purpose seeds are usually sown early in February, and from then onwards until well into March, so that if seeds are procured and sown at once, good plants should be available for the outdoor garden by the second or third week in May. Well-drained boxes or pans, filled with soil composed of good loam two parts, coarse grit one part, and a little sweet leaf-soil or old manure, should be used for seed-sowing, which must be done thinly, and the seeds lightly covered with fine soil. If placed in a warm greenhouse or frame, the seedlings soon appear, and should be early transplanted to other boxes or pans filled

BORDERS OF ANNUAL FLOWERS AT GARNONS, HEREFORD. THESE BORDERS WERE FILLED WITH TULIPS IN THE SPRING.

with similar soil to that already advised, except that rather more decayed manure and, if available, a little old mortar may with advantage be added. The seedlings should be placed 3 inches apart each way, as it is highly essential that sturdy, branching young plants be secured. With this end in view, free ventilation, as soon as the seedlings are established, must be given, and they must be kept near the glass. If in a frame, the lights may be entirely removed on bright, sunny days. About the second or third week in May, or even a little later, the young plants should be put out about a foot apart in their permanent quarters, and from early July right on until severe frosts are experienced they will give a bounteous display of flowers.

When treated as biennials, it is usual to sow the seed in the open garden in June or July, subsequently transplanting the seedlings either into other beds, and later still into their flowering quarters, or direct into the latter positions, whichever method is adopted being a matter of convenience. Plants raised in this way commence to flower in early summer, and continue to do so, as a rule, well into the autumn. It is, however, essential to remove seed-pods and old flower-stalks as frequently as possible. Named varieties are sometimes increased by means of cuttings; but as most of the colours come true from seed and the seedling plants usually possess the greater vitality, few care to bother with cuttings. We prefer the tall and medium types of Snapdragons to the dwarf, stunted section, which, however, some like to use as an edging to beds. It is, however, but a poor example of a beautiful race of flowers. With the wide range of colours available, it would be invidious to specially mention any by name. All that are offered by seed firms of repute are good.

IRIS SIBIRICA AND ITS VARIETIES.

The numerous varieties of this handsome and well-known species are all possessed of exceptional merit as garden plants. All the forms are exceedingly graceful and are most pleasing when grown together in clumps or massed for effect. For grouping together on the margins of a pond or water-course there are few subjects so delightful, the lavender blue and violet coloured varieties being particularly useful for this purpose, forming bright and most pleasing masses of colour in the landscape. In choosing a position in which to plant, the chief consideration should be to secure one where the plants will receive full sunshine at all times, preferably one adjoining or in the vicinity of a plentiful water supply.

All the varieties are gross feeders and prefer an alluvial soil rich in humus, such as leaf-mould or well-decayed manure, and they will repay any extra trouble taken in order to give them a good start; in fact, there are few plants of such easy culture when their requirements are properly understood. Of course, to plant them in a dry position or in poor, sandy soil is courting failure at the commencement.

When to Plant.—Another point is that they should be replanted at the right time. The proper time to replant this and, in fact, all other species of this extensive genus is immediately after they have finished flowering, not in the winter period, as is the case with most herbaceous plants. It is

so detrimental to success as deep planting. All the rhizomatous Irises produce their rhizomes along the surface of the soil, and this points to the idea that sunshine is essential to success. The primary roots of practically all the genus have the habit of striking straight downwards, and once these have developed, any disturbance afterwards is distasteful to the plants, so much so that even the operation of forking between the clumps will often cause them to fail to produce their flowers.

The Best Varieties.—Of the numerous varieties of *I. sibirica* which are worth growing, I can recommend the following, all of which may be purchased from nurserymen at from 3d.

to 9d. each: *sibirica* (type), standard (or petals) light blue, fall (or sepals) purplish blue, reticulated; *alba*, pure white; *Snow Queen*, a fine white variety with rather larger flowers than the type; *atropurpurea*, a rich deep purple; *acuta*, deep blue falls, white reticulations and of dwarf, compact habit; *furcata*, white, falls reticulated with yellow; *lactea*, white, reticulated with brown; *Melpomene*, a dwarf variety with white flowers; and *Baxteri*, blue, with white falls.

In his recent monograph of the genus *Iris*, Mr. W. R. Dykes suggests that *I. sibirica* is confined to Central Europe and Russia, and that the Siberian plant is *I. orientalis*. He points out that the two plants may be readily distinguished by their fruits and seeds, and illustrates their distinguishing characters with some exquisite coloured plates. Apart from their fruits and seeds, the two plants may be readily distinguished by their habit of flowering, the blossoms of *I. sibirica* being borne on long, slender stems often twice the length of the leaves, while those of *I. orientalis* are on short stems partly hidden among the leaves or barely rising above them.

P. C. RAFFILL.

A SUMMER BED OF MIXED CANDYTUFT. IN THE SPRING THIS BED WAS MADE BEAUTIFUL WITH DARWIN TULIPS AND THE CANDYTUFT SEED WAS SOWN BETWEEN THEM IN APRIL. (See page 107)

RAISING ASTERS IN COLD FRAMES.

It is, I think, safe to assert that there are no more delightful flowers grown in our gardens than these, and it is therefore regrettable that they should so seldom be seen in perfection. Of course, hundreds of amateurs produce magnificent blooms, but thousands of others have flowers of mediocre or poor quality. The reasons for this are not easy to indicate. Beyond question the point of initial importance is to procure seeds from a source of the first repute; but this presents no difficulties. Then the seeds must be sown sensibly and the plants treated rationally throughout, and these things are not invariably done. Then the soil must be clean and not made

immediately after the flowers are over that the new growths are made with their accompanying new roots, and any necessary division or replanting should precede the new growth. In the case of *I. sibirica* this should be done about July, but is liable to vary slightly from year to year. If replanted at the proper season, there is sufficient time for them to become established in their new quarters before the winter period, and most of the plants will flower the following year. In planting it is important that the rhizomes should be kept on or near the surface, as there is nothing

work with excessive dressings of manure, as is far too commonly seen. The growers then wonder why their plants collapse—the real marvel would be if they lived in health in such unsatisfactory conditions. The fact of the matter is that the idea is gaining ground that manure will take the place of mechanical cultivation. Those who hold this impression must disabuse their minds of it at once if they desire to achieve real success in the garden.

The point raised as to purchasing seeds of the finest quality has been practically disposed of already, since there are many seedsmen upon whom complete reliance may be placed. For example, Messrs. E. Webb and Son have a particularly choice strain of Comet Aster. The quality of the blooms can be seen in the illustration on page 110.

that direction often end in dire failure. The earlier the seeds are sown and the warmer the structure in which the seed-boxes are placed, the greater the trouble of culture and the more the chances of loss and disappointment. Given a cold frame, even a box with a piece of glass over it, some sweet, fine, friable soil, and intelligence, everything essential to success is at command. Let there be a generous proportion of sweet leaf-mould and sharp sand in the soil, and make the surface firm and level prior to the distribution, evenly and very thinly, of the seeds. It must, of course, be pleasantly moist, and it is then improbable that more water will be needed until the seedlings are through. As regards the time of sowing, one has latitude, since any day between the end of the

base of humus already present, it is best wisely to rely upon a little artificial fertility, such as may be found in organic manures. There are plenty of excellent plant foods advertised in the literature that can be advantageously used according to directions, or a home-made compound of superphosphate and sulphate of potash may be applied. In any case, let the dressing be made three weeks, and preferably one month, before the planting is done. F. R.

THE HEATH GARDEN.

HOW TO MAKE AND MAINTAIN IT.—In these days, when fashion has given a healthy impetus to the improvement of flower gardening

AN EFFECTIVE GROUPING OF IRIS SIBIRICA BY THE WATER-SIDE AT KIW

but the range of rebbed and charming colours is not reproduced. In case some captious critic should cavil at the two or three single plants observable, let it at once be said that they were planted as hill-ups, and the proud owner knew they would come sooner or later and detract a little from the effect.

Sowing the Seed.—The next point which shall be passed in review is the seeding. No artificial heat whatever is necessary; indeed, I am inclined strongly to the view that it is not desirable. Amateurs with heated frames and greenhouses are almost sure to sow the seeds too early, with the inevitable result that endless worry and trouble are involved in keeping the plants sturdy, strong and compact, and, unfortunately, all efforts in

third week of March and a similar time in April will answer splendidly. The seeding ought to be so thin that thinning will not be required, and when the available space is filled, prick the youngsters out in a bed to strengthen. Here they will make many roots, and about the end of May they should go into their flowering quarters. Moderately firm planting is necessary, and the distance asunder will obviously vary with the varieties cultivated. The plants shown in the illustration were raised in a cold frame on the lines indicated above.

Then as to the soil, it must be in perfect physical condition, and there must be a supply of food. To ensure the first named one digs deeply, taking small bites, and to provide the second essential one adds manure; but where there is a

in all its aspects, including rock, water and wall gardening, as well as a revival of topiary work, it may not be out of place to enter a special plea for a more extended use of this interesting race of hardy plants; and if one could imitate the graphic pen of a Reginald Farrer and so describe the many gems contained in the genus, their easily-understood and modest requirements, together with the knowledge that they provide an inexpensive hobby which may be enjoyed equally by those looking for further extension to their pleasure grounds or those possessing only a small strip of ground which may be unsuitable for other styles of gardening, then the formation of Heath gardens would soon become general.

The genus *Frica*, belonging to the Natural Order Ericaceae is said to contain between four hundred

and five hundred species, the majority of which come from South Africa, the others being natives of Britain and Southern Europe. The common Heath or Ling, *Erica vulgaris* or *Calluna vulgaris*, so plentiful in the Highlands of Scotland and on moors in England, is said to extend to North America, but only in small quantities. The South African species were at one time largely grown as greenhouse plants, but few of them are now in cultivation, their places being filled by numerous soft-wooded hybrids which are largely grown on the Continent for autumn and winter decoration; but it is of the varieties that have proved hardy in Britain that I propose to treat. A full collection or a selection of those best suited to the climate may be had to provide a succession of flower almost throughout the year; indeed, it may be said that the Heath garden is never entirely devoid of flowers unless when the plants are buried deep in snow. Those flowering in late autumn retain their flowers, with very little diminution in the bright colours, through the dull months of November and December, and after the plants are entirely denuded of flowers, numerous varieties show such a distinction and contrast in the colouring of the foliage—some silvery, some golden, and others bronzy or russety—that they are not without decorative effect, while such varieties as *E. multiflora*, *E. arborea* and *E. codonodes* will, by the end of the year, be pushing out their delicate flowers until arrested by severe frost or a heavy coating of snow, only to reappear with renewed beauty as soon as the sun has proved strong enough to melt the snow on the higher shoots. These three are followed in quick succession by a host of spring and early summer flowering varieties, a list of which I propose to give later on, with their respective colours and habits.

The increased demand now shown for all kinds of outdoor gardening, and especially for hardy plants, has been the means of bringing this highly interesting genus into more prominence than it has perhaps hitherto enjoyed; and while it cannot be claimed that it has the reputation of having an accommodating nature, its wants, when properly understood, are easily satisfied.

Situation and Soil.—The situation chosen for the Heath garden should be one having a southern aspect, if possible, or on a sunny slope leading from the formal flower garden to the shrubbery or plantation, a sort of connecting link, in fact, between the purely artificial and the natural. The place selected must be thoroughly drained, it not naturally a dry spot, for these plants will not thrive with any excess of moisture about the roots, and the soil, if of a heavy, retentive nature, or containing much lime, would require to be removed and replaced with a mixture of peat, leaf-mould and sand or grit. Should the natural soil be a light, sandy loam, however, none of these ingredients will be required. Fortunately, or unfortunately, I have here a soil in which all sorts of hardy Heaths grow and luxuriate without any assistance, but which requires heavy manuring and other ingredients to produce crops of fruit and vegetables, the tinnest scrap of Heath with but few roots attached being generally sufficient to

establish strong plants in a very short time. As an instance of the ease with which these plants can be grown when the soil is suitable, we have a section of the kitchen garden walks edged with *Erica carnea* and *E. c. alba* as a substitute for the usual Box edging; these grow with such rapidity that, although clipped annually, they have to be lifted and replanted every few years. The effect in early spring, when the lines (about eighteen inches in width) are an unbroken mass of flowers, is one to be envied by those who find a difficulty in getting these plants to thrive.

Formation of the Heath Garden.—As I have already said, the situation of the Heath garden may form an adjunct to the formal flower garden, or it may be an extension or addition to the rock garden; and a very pretty effect may be obtained if a piece of ground is selected which has a decided

do not, as a rule, molest the Heaths, protecting fences, which often prove a difficulty, need not be considered. The positions of the beds having been determined, these should be excavated to a depth of 1½ feet to 2 feet and filled in with the mixture already mentioned. Planting may be safely undertaken during favourable weather, either in autumn or spring. The fringes of shrubberies or large borders might also be made more interesting by the addition of numerous varieties of the Heath, disposing them in large, bold clumps or in bays formed by taller-growing subjects. Edgings of some of the dwarfier, free-growing sorts might be formed around the margin of all beds or borders containing hardy shrubs. There are also numerous varieties that do not exceed 6 inches in height which might find a place in the rockery, their stations being filled with a suitable compost. T. WILSON.

The Gardens, Glamis Castle, N.B.

(To be continued.)

A BED OF MIXED COMET ASTERS. THESE WERE RAISED FROM SEED SOWN IN A COLD FRAME IN MARCH. (See page 108.)

slope with an undulating surface, where beds of irregular shapes and sizes could be made to harmonise with the existing surroundings. A plantation or belt of timber on the north and east of the site, if an exposed one, would give shelter to visitors and do no harm to the plants; while a rustic summer-house, thatched with Heather obtained from some friendly owner of a grouse moor, erected on a spot to command a good view of the garden, would add to the general comfort and appearance. Avoid geometrical designs or the making of gravel paths, which I do not think are in keeping with the subject under notice. Beds cut out in grass, so that when in full growth the plants may appear as if growing naturally in clumps out of the turf, give the best effect. The grass will require to be kept regularly mown, so that each bed may be examined conveniently. As vermin

white, a strong grower), umbilicata (rich rose), sulphurea perfecta, and flore pleno (semi-double, red). A closely-allied species, *C. Maulet*, with orange scarlet flowers, is also blooming freely. Or this, *alba, superba* (dark red) and *Leichtlinii* (red) are distinct varieties. Layering forms a ready means of increasing these Quinces.

SOME GOOD WINTER TREES AND SHRUBS.

Prunus davidiana alba.—This, although it flowered abnormally early this season, is one of our earliest-flowering trees, and during the first week of the New Year was one of the greatest attractions in the garden. Owing to its blossoms being pure white, it is not so readily seen as many others of the *Prunus* family; but when the long, whip-like growths, studded with flowers, are caught in the

TREES AND SHRUBS.

THE JAPANESE QUINCES.

WE are so accustomed to the red-flowered form of *Cydonia japonica* that the other distinct and varicoloured varieties are

apt to be neglected. The mild weather of the present winter at Kew has been especially favourable for the different forms growing in the border near the Pagoda. For nearly two months now the notice boards at the entrance gates have indicated to visitors that the *Cydonias* are an object of special interest. Near the Pagoda the plants are grown as bushes, while at the other end of the Gardens several plants are flowering freely against a wall. The protection afforded the latter is very beneficial during an ordinary winter. Among an interesting and varied list of varieties, the following will be found a useful selection for walls, fences, or grown as bushes in a border (in most instances the name indicates the colour of the flowers): *C. japonica* (red), *Aurora* (pale salmon pink), *alba, atrococcinea, candida* or *candicans* (pale sulphur white, very free), *luteo viridis* (yellow, shaded green), *Meerloezii* (pink and

right light, it is a beautiful picture. The tree is of pyramidal growth, with branches arising from the base almost as fastigiate as a Lombardy Poplar and some 18 feet in height, and every year blossoms in spite of the weather prevailing at the time, though I have never seen it so thickly laden as at this season. The five-petalled flowers are produced in ones and twos the entire length of last year's growth, and are barely an inch in diameter.

Cornus Mas.—This deciduous species, commonly known as the Cornelian Cherry, from the fact that established bushes produce fruits resembling a long Cherry, has flowered profusely. It occurs wild in the North of Asia in hedges and among bushes, and the wood, being exceptionally hard, is, I believe, used for making skewers, tooth-picks and similar articles. In this country, however, it forms a fairly slow-growing, compact bush, and at this season is attractive because of its minute yellow flowers, which are particularly pleasing and interesting. In addition to the type there are one or two forms which produce prettily-variegated foliage, and especially good is the variety *C. Mas foliis aureis variegatis*.

Aralia chinensis.—To those who have a considerable amount of planting to do, and who do not know the merits of this shrub, I would strongly recommend it. The name by which it is now recognised is certainly much more suitable than *Dunorphanthus mandshurica*, under which it is often met with. It is perfectly hardy, will thrive anywhere, and produces large and elegant foliage, which, however, falls at the first touch of frost. The stems, which are prickly, are quite hardy, and attain a height of 10 feet or so. When once established this subject may easily be propagated by suckers, which arise from the base. During the summer its appearance is considerably enhanced by the large trusses of flower, which, if not individually beautiful, give the plant a further sub-tropical appearance. There are two variegated forms of this shrub, one bearing silver, the other golden variegation. Both are pleasingly marked and totally distinct from each other. As the leaves have a great spread when fully matured, abundance of room must be allotted the shrubs when planting, a matter which might easily be overlooked, as when denuded of their foliage one can hardly imagine them to be the same plants.

Cotoneaster pannosa.—This evergreen Cotoneaster, hailing from Yunnan, is one of the finest berried winter shrubs we have, and has been literally covered with its somewhat small red fruits as compared with some of the other members of the genus. It certainly is one out of the numerous species and varieties now grown that cannot be omitted, and it has been in commerce some time. It makes a splendid specimen for a lawn as we grow it here, as it has quite a graceful habit with its drooping, slender branches and its small greyish green leaves. On our cold, wet soil we have found it quite hardy during the last few winters, though it is one of those shrubs that might be tried against a wall, where it would make a good effect.

Aldenham House, Elstree. EDWIN BECKETT

THE KITCHEN GARDEN.

GARDEN PEAS.

PEA S form one of our most popular garden crops, and may be grown in almost any garden providing the ground is properly prepared for them. The Pea is a deep-rooting and moisture-loving plant, and only when the soil has been thoroughly prepared can the best results be obtained; but, given these conditions, and by frequent sowings, a continual supply of young pods may be kept up from May till October, or even November if the weather is favourable. To grow Peas to perfection it is necessary to trench and prepare the land early in winter and to mix a liberal supply of decomposed farmyard manure with the soil as the work proceeds.

selected for sowing. For instance, a 4-foot Pea should be allowed 6 feet between the rows, and, if necessary, a line of Spinach or some other quick-growing crop may be sown between the rows, to be gathered before the season is too far advanced, as nothing of this kind should be allowed to remain long enough to obstruct the free passage of light and air among the plants. The drills in which the seeds are sown should be at least 4 inches deep, and the seeds covered with 2 inches of the finest soil from the surface of the bed which has been exposed to the weather during the winter, and the soil taken from the drills may be allowed to remain as a protection to the young plants from cold east wind during the early spring. When a few inches high, this soil may be carefully worked in among them before the sticks are placed in position, thus leaving the ground almost level, instead of drawing the soil up to the plants in ridges.

PEA INTERNATIONAL, A NEW LARGE-PODDED MAINCROP VARIETY OF GOOD CROPPING QUALITIES AND EXCELLENT FLAVOUR. (*Much reduced*)

When to Sow.—At Frognore we make our first sowing in the open as early in January as the state of the soil will permit. For the earliest and latest sowings a sheltered position should be chosen, in order to obtain some protection from rough wind, for although young Pea plants will stand several degrees of frost without injury, the effect of rough wind upon them is very detrimental. For the earliest sowings, only hardy, round-seeded varieties should be chosen, and the rows should run from north to south, in order to secure the maximum of light and air. There is great risk in sowing the best wrinkled varieties before the middle of March, and only then if the weather and the state of the soil are favourable. If this rule was more generally adopted, there would be fewer failures with this class of Pea, especially in cold, wet seasons.

Preparing the Drills.—The space between the rows must be governed by the height of the varieties

like manner and casting off the rain-water, which is so necessary for the production of first-class Peas.

For midsummer or maincrop varieties an open position should be chosen, and the seeds may be sown thinner as the season advances, in order to promote robust growth and render the plants less likely to suffer from mildew than if crowded together, as they frequently are. For the latest sowings, which should take place early in June, a position should be chosen with some natural protection from rough west wind, which often proves disastrous during the autumn. This is a very important matter where an unbroken supply has to be maintained throughout the season.

In all cases, before the plants are staked a number of small twigs should be placed as close to the plants as possible, in order to keep them in an upright position until their tendrils reach the sticks.

Pests.—If once the plants are allowed to suffer from insufficient moisture at the roots, the evil cannot be effectually remedied; but it may be prevented to a great extent by timely and effectual watering and mulching. There is no more fertile cause of mildew among Peas than an insufficient supply of moisture. Peas suffer greatly from the depredations of numerous kinds of vermin, and sparrows in particular, which should be guarded against by placing wire guards over the rows or by covering the bed with fish-netting as soon as the young plants appear above the surface of the soil. If slugs are troublesome, there is no better remedy than dusting the plants with soot which has been exposed to the air for some time previous to use, and this should be applied early in the morning, when the atmosphere is moist.

Varieties.—For early sowing there is no more reliable Pea than *The Pilot*, from which we gathered our first supplies on May 24 last year. The seeds were sown early in January on a south border, in trenches 4 inches deep, and covered with 2 inches of fine soil. This Pea was raised a few years ago by Messrs. Alex. Dickson and Sons, and is rapidly gaining favour both in market and private gardens. Other varieties to follow *The Pilot* should include *Veitch's Acme*. This Pea has a flavour quite its own, and it sown at the end of February should be ready to gather about the middle of June. If dwarf varieties are desired for early sowing, they should include *Little Marvel* and *Reading Wonder*, the latter being one of the earliest dwarf Peas in cultivation. *Sutton's Seedling* and *Langley Gem* are also very fine dwarf Peas. For the second division we have *Gradus*, *Early Grant* and *Dame's Matchless Marrow*, all of them fine Peas for second sowing, and will follow the first crop for succession. In main crop varieties *Royal Salute* is one of the best. *Sutton's Superlative*, *Alderman* and *Discovery* are all good. For the latest division, *Cheltenham*, which is a strong-growing variety of the *Ne Plus Ultra* type; *Distinction*, a fine late Pea which resists mildew well; *Rear-guard*, a new late variety of fine quality; and *Autocrat* are all to be recommended. For exhibition purposes there is none to equal *Carter's Quite Content*.

Royal Gardens, Windsor.

JOHN DUNN

GOOD POTATOES FOR SPRING PLANTING.

The garden in which vegetables are grown would be lacking the most important of economic plants were the Potato to be excluded, and, happily, such a peculiar method of cropping is rarely seen. It is often impossible, in these days of small gardens, even attached to houses in the country, where the land cannot be worth many pounds sterling to the square foot, to produce enough of the noble tuber to serve the year round—but space must always be found for a few rows of early varieties

because no Potatoes can be bought that will equal those dug from one's own garden. This should apply to each successive group, but it is much more pronounced with the first earlies than it is with those grown for main crop and late use.

Having convinced one's self of the paramount importance of the Potato crop, it should not be difficult to grasp the value of proper soil preparation, of procuring perfect seed tubers, of planting carefully, and of sprouting the sets before consigning them to Mother Earth. The particular size of set utilised has a substantial bearing upon

A GOOD CROP OF POTATO ROYALTY, A WHITE MID-SEASON VARIETY WITH DWARF, BRANCHING HAULM.

the ultimate results, and experience in many directions goes to prove that an average weight of 30z. cannot be beaten.

Preparing the Sets.—The advantages of sprouting lie in the production of a more vigorous plant, which will have greater powers of resisting the disease than one that has been grown from an unprepared set; in the prevention of gappy lines in a quarter, since the tuber which will produce a strong sprout will give a fine plant; and in the fact that one can plant later and harvest the crop quite as soon. This latter is a point of importance, in view of the injury resulting from late spring frosts. It is wise, too, in addition to sprouting the seed sets, to damp them thoroughly once or twice with Bordeaux mixture with a view to reducing the serious effects of the blight. It is

well known that spores cling in the soil on the skins and also congregate in the buds, and it is from these that the first growths of the murrain appear rather than from resting spores in the soil. The old method of dusting the tubers with lime was good, but there can be little doubt that the copper sulphate solution is decidedly better. The only objection that I have heard raised to the system is that it may prejudice the progress of the plants, but proof to the exact contrary is not difficult to adduce.

Another point in connection with seed sets is to procure them from an outside source every year.

The practice of saving at home is wrong, and has ended in the ruin of more than one magnificent variety. Buy seed from some different soil and climate—any source rather than one's own district; but avoid South of England seed, especially from light, sandy lands, as one would avoid the plague, because it throws too big a proportion of poor plants, and the plants are liable to disease.

In choosing Potatoes one is presented with the difficulty that certain varieties will grow in one garden and not in another, even though only a few hundred yards may separate them. There are, however, some Potatoes which flourish satisfactorily in the majority of places, and it is now purposed to mention them.

Some Good Varieties.—A splendid set is *Carter's trio*, *Early Favourite*, *Royalty* and *Long Keeper*. In regard to the second named, it is worthy of note that the tubers are still in excellent condition and are cooking magnificently, although it is classed as a second-early variety. One could not go in for Potato cultivation without trying *Sutton's varieties*, of which such earlies as *May Queen*, *Ringleader* and *Epicure* have made a reputation which will last for many years, whether one writes of them or not; while *Balmoral Castle* and *White City* are grand for later use. *Sutton's*, by the way, advocate yellow for quality, and they are right in this, as in so many other things that they do.

A Scottish set that will please comprises *Middlethian Early* (probably one of the finest early Potatoes ever introduced), *Prolific* and *The Factor*; and *Dobbie's* strain of the old *Windsor Castle* requires a lot of beating for home use. *Dickson's* recommend *Early Queen*, *New Century* and *Eastern Planet*, and trial has demonstrated that the three varieties are fully entitled to all the good things that the firm claims for them. Irish seed has become renowned in recent years. Mr. Sands is keen on *Erin's Queen* and *Irish Hero*, but he does not forget to speak words of commendation regarding the excellent *Colleen*. One could, however, write far more of fine Potatoes. All growers should select the varieties which they know to be good and try those mentioned above, if they have not already done so, in the hope that one or more of them will turn out superior to the established favourites.

H. J.

GARDENING FOR BEGINNERS.

HOW TO GROW TOMATOES UNDER GLASS.

THE cultivator who can command a fair amount of artificial heat in his glass structure may sow seeds of Tomatoes at once. Those who are only able to heat their structures sufficiently to keep out frost should not sow the seeds for another fortnight, as then the heat from the sun will be of great benefit.

The best position for Tomato plants is one fully exposed to the sunshine, and the atmosphere in the house must be dry; then there will be no diseased leaves or fruits. Even the lower portion of each plant should be quite exposed to the sun's rays; then there will be a possibility of fruit forming from the base to the top, which means earliness and a greater weight of Tomatoes.

Raising the Seedlings.—Through experimenting and experience generally, I have found it best to sow the seeds in some good, new loam which has been stacked about four months, and coarse sand with only a very small proportion of leaf-soil. The resultant seedlings grow very sturdily in such a mixture, and few decay at the soil-level. In a light compost, with a large quantity of leaf-soil in it, many seedlings die suddenly in this way. Do not cover the seed pot or pan with glass or paper, as in such circumstances the seedlings come up weakly. Avoid overcrowding from the seedling stage onwards, the seedlings in Fig. 1 being rather too thick. Under these circumstances the seedlings must be pricked off in the very early stages, as soon as they can be handled, placing them in boxes as depicted in Fig. 2. Until the seedlings have grown about three inches high, apply water by immersing the pots or boxes.

Soil for the Permanent Bed or Pots.—A narrow border is the best in which to plant the Tomatoes, but, as previously stated, it must be fully exposed to the sun. Ten-inch and 12-inch pots are more suitable than boxes if the plants are grown on a stage. In every case thorough drainage is essential to success. If grown on a border in the house and the stems are trained to stakes or strings, the soil must be deeply dug and then trodden firm again before the Tomatoes are planted. Neither chemical nor organic manures must be added to the border soil nor that placed in pots or boxes, as the necessary feeding must be done after the two basal bunches of fruits have set. The first layer of soil should not exceed 7 inches in depth, and later on surface-dressings half an inch deep should be put on the roots. All soils used must be made firm.

Training the Plants.—This simply consists of restricting each plant to one main stem, or the removal, while in a very small state, of all side shoots, keeping the main stem, main leaves and bunches of fruits only; then, if the plants are disposed 18 inches apart, they will have every chance to do well.

Other Necessary Work.—Free ventilation in mild weather is good for the plants generally; a teaspoonful per plant of superphosphate every ten days and weak doses of manure-water weekly

1—TOMATO SEEDLINGS READY TO BE PRICKED OFF. THE SEED IN THIS INSTANCE WAS SOWN TOO THICKLY.

may be given. Other concentrated manures advertised in THE GARDEN may also be used according to the instructions given with them, but not pure nitrate of soda nor sulphate of ammonia. When in flower, the trusses should be gently tapped at noon on all fine days. A bigger "set" of fruit would then result. Frogmore Selected and Sunrise are good varieties to grow. AVON.

HOW TO MAKE AND PLANT A HERBACEOUS BORDER.

WHEN first confronted with the project of making and planting a herbaceous border, the inexperienced cultivator of the plants mostly used is at a loss as to what to do and how to begin the work. Usually, this work is done without much serious thought and consideration as to the kinds of plants to put in, their disposition and their season of flowering. Then there are the minor details, such as height of each kind, the spreading or erect habit, and the very important matters of colour blending, contrast, and the securing of harmony from season

to season. Too often all these vital points are ignored, with the result that one sees herbaceous borders which are eyesores during a great part of the year. The position of the border should be an open one, and the soil the best that is possible. The flowers will well repay the best treatment that can be given, and the beginner should endeavour to excel in their cultivation.

Trenching the Soil.—Soils of all kinds should be deeply trenched before any plants are put in. Herbaceous plants, generally, are improved by frequent lifting, division and replanting; but there is no time more suitable for dealing with the soil than that before the border is filled. If very poor, add some rotted manure to the soil as the work of trenching goes on. Thoroughly break up the sub-soil, but leave it below. The top portion need not be broken so finely, as it will be separated through the planting and by the action of the weather on it afterwards; and if of a heavy, retentive nature, it will also be considerably sweetened.

The Broad Border.—If the border to be dealt with is a broad one—we will say 9 feet wide—the tallest-growing kinds of herbaceous plants may be put in near the back of it; in fact, there will be sufficient space for all the leading kinds of various heights, both at the back, in the centre and in the front portion. Furthermore, each clump of plants must be of considerable size.

The Narrow Borders are more numerous than broad ones, and are more difficult to furnish satisfactorily. Very tall-growing plants must not be used unless as isolated specimens, well apart, the medium and dwarf growing kinds being the best. Whereas in the large border plants may be grouped in fives, sevens and nines, in the narrow border threes and fives are the more suitable. SHAMROCK.

PROPAGATION OF THE LEMON-SCENTED VERBENA.

THIS plant, correctly known as *Lippia citrodora*, may be increased freely during the spring and summer months by adopting the following methods: Place the old plants in the greenhouse or on a hot-bed, and water them. Spray them over daily until growth commences. When the young shoots are from 1½ inches to 2 inches in length, take a very sharp knife and sever them from the plant with a heel attached. Insert them around the edges of small pots, which are filled with very sandy soil. Make the soil very firm. Plunge the pots on the hot-bed, and place over them a hand-light or bell-glass. Provide shade during spells of bright sunshine. Keep the soil moist. Later in the season cuttings may be rooted without the aid of bottom-heat. The pots should, however, always be plunged in some moisture-retaining material, and be covered by a glass as advised above. Success is often attained by these simple methods, while failure sometimes follows attempts to propagate this delightful old plant by a more elaborate system in the stove or propagating house. C. RISE.

2—THE SEEDLINGS ARE TAKEN FROM THE POT AND PRICKED OFF 1½ INCHES APART IN BOXES.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Bedding Plants.—Continue the propagation of all such subjects until the desired stock is raised, potting or boxing off those already rooted as they become fit.

Surplus Herbaceous Plants.—Where large quantities of cut flowers are required, the surplus plants or offsets should be planted in beds in some out-of-the-way part of the garden, and where they may be cut from without depleting the herbaceous borders.

Seed-Sowing.—Many bedding plants are raised annually from seed, and, among others, the following should now be sown: Lobelia, Pyrethrum, Variegated Maize, Ornamental Beet, Statice, Nemesias, Celosias, Alyssum maritimum, Phlox Drummondii, Amaranthus, Perillas and Kochias. Thin sowing and an intermediate temperature are far the best for these plants, as they come more sturdy and need far less hardening off than when subjected, say, to a stove heat.

Plants Under Glass.

Begonias.—Winter-flowering Begonias that may have gone out of flower and been given a rest may now be cut back pretty hard, and if placed in a warm, moist house will soon begin to throw some good cuttings, though it is full early yet to commence propagating the main batch, as rather later cuttings often make the best plants.

Begonia haagiana.—This is one of the foliage Begonias that are exceptionally useful either in the house or conservatory, and stands well for a long time even in a very dark situation. Cuttings put in now, three in a 3-inch pot, may be grown on into 8½-inch pots by the autumn, and without any pinching or training make quite good specimen plants.

Tuberous Begonias.—The present is also a good time for starting these for pot work, shaking them quite free of all soil, and placing them in boxes in a very light mixture of leaf-soil and sand. Here they will quickly make roots, and should be potted before they have made much top growth.

Pot Roses are now well in growth, and may be led liberally as soon as the buds show. Climbers planted out in the houses will likewise be benefited by copious waterings of liquid manure, or occasionally a dressing of artificial. As the days get warmer and more ventilation is necessary, mildew is apt to be troublesome, so the plants must be either sprayed with a fungicide or given a very light dusting of black sulphur. This ought to be done as a preventive, rather than leave it till the plants are badly infested or the beauty of the foliage is lost.

Climbers such as Rose Dorothy Perkins, Excelsa, Tausendschön, Paradise, Goldfinch and Lady Gay may now be introduced into a little warmth, and they will make a nice succession to the earlier batches of Teas and Hybrid Teas. Plenty of room should be allowed between these tall plants to allow a proper development of the lower shoots, or it may be found that the top shoots only will produce good flowers, and thus mitigate considerably the usefulness of this class of plant.

The Kitchen Garden.

Onions and Leeks.—Sown in the early part of the year, the seedlings should now be advanced enough for pricking out, 2 inches or 3 inches apart, in boxes or in frames on a slight hot-bed, where they can remain till put out in the ground during April.

Cauliflowers.—These also will need attention, and though the above system will suit them well, I prefer to pot them off singly in 3-inch pots. A little heat is necessary immediately after pricking out or potting off, but as soon as they get hold of the fresh soil they may be hardened off in the cold frame.

Lettuces should also be pricked off as soon as large enough to handle, and to secure an early crop they also should be pricked off in frames placed on a hot-bed. Seedlings that may have been sown in rows between the Horn Carrots should be thinned out, and as this crop should be cleared off as early as possible, they may be left

moderately close together and cut before they overgrow the Carrots in any way.

Peas and Beans raised in heat should be hardened off before they become at all attenuated, choosing a mild day for removing them to the cold frame. A further sowing of one or two exhibition varieties may be made in pots or boxes. These I find often make better and stronger plants after being planted out than do those raised in the open ground.

Parsley.—Though full early, a sowing should be made on a warm border, making the soil very fine before sowing the seed. This will come in before the main summer sowing, and possibly prevent a gap between this latter and the batch sown in August or September.

Fruits Under Glass.

Peaches.—Continue the disbudding as the trees get sufficiently advanced, and heeling in should also be commenced as soon as the shoots are long enough. Delay in this matter means curved and unsightly shoots, which no amount of attention at a later date will obviate.

Thinning the Fruit.—This is an operation that should be carried out gradually, leaving at least one-third more on the trees than is ultimately wanted for a crop till after the stoning period, this to counter-balance any loss that may be sustained during this critical time. Unfortunately, I have come across several gardens this season where the amount of blossom on the trees will hardly leave any surplus for thinning.

Hardy Fruit.

Apricots, Peaches and Neclarines.—Where tying or nailing has not already been done, it should be proceeded with at once. Many growers leave this as late as possible, keeping the shoots from the walls to delay blooming, and this is a good plan. But all flower-buds are very forward this season, and already those of some varieties are almost open, so further delay is dangerous.

Protection.—Where protection is provided for the above by means of blinds or canvas that can be let down at night, it should be fixed in position, as a severe frost might mean ruin to practically all the bloom-buds. Where no other protection is at hand, a fish-net, doubled, hung at a distance of 1 foot from the wall, will do a lot of good, and such a protection may with advantage be given to the Plums and Pears on the walls, as well as the Peaches.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Primula Sieboldii.—The varieties of this Primula are worthy of more extended cultivation. Here we have several beds of them, and they are gorgeous during the month of May. Those who have masses of them should at this season apply a slight top-dressing of some rich, light material. This is also a good time to plant. Avoid a southern exposure, give them a rich, friable soil with a cool bottom, and success is assured.

Sanguinaria canadensis.—The pure white flowers of this dwarf border plant are rather fragile and short-lived, but it should be in every collection. Those wishing to plant it should do so without delay. Give it a free soil, and it will be grateful for a slight admixture of peat in the compost.

Erica herbacea.—This harbinger of spring differs from most Heaths, in that it can be quite happy without peat, especially if it gets some sand and half-rotted Beech leaves. It will now have almost finished flowering, and may be increased by division. I once saw a large-sized bed of this Heath on a lawn in a Fife-shire garden, and the effect in early spring was very fine. E. h. alba is also good.

Salvia patens.—This Salvia gives us one of our finest blues, and is indispensable. It can be raised from seed in heat, which should be attended to forthwith. Old tubers may also be placed in heat to furnish cuttings.

Calceolarias.—Calceolaria amplexicaulis and any other bedding varieties should now be "lued off" in frames, placing some flaky leaf-mould or the

rough siftings of loam under the compost, so that the plants may lift with good balls at planting-time.

The Shrubbery.

Pruning Evergreens.—Such vigorous evergreens as Laurels and Laurustinus may now be pruned. A start should be made with the Portugal Laurels. Whatever form is adopted, stiffness should be avoided. The knife is generally recommended for this work, but if judiciously used the pruning-shears will do the work equally well and more expeditiously. Where pruning has been neglected, however, the knife should be employed and the offending branch cut back considerably beyond the general surface of the bush.

Tree Pæonies.—Where these are employed in the shrubbery, a light framework should be placed round them for a few weeks, to support the protecting mat, when frost occurs to imperil the young, tender shoots.

The Pleasure Grounds.

Garden Furniture.—The time is not far distant when garden seats, hammocks and tennis nets will again be called into use. The whole should be overhauled, and any necessary repairs executed and painting done. For garden seats, Oak-grained or plain or a quiet olive green are the shades to be preferred. A coat of clear varnish will greatly help to preserve the paint.

Lawns should be well swept to disperse worm-casts and be afterwards rolled.

Plants Under Glass.

Gesneras and Nægeliæ.—These two genera are often treated of as being synonymous, and from the cultivator's point of view they are so. In addition to the named sorts, innumerable varieties of seedlings are in commerce. Such old favourites as zebrina and cinnabarina are indispensable. A batch should now be started.

Deciduous Calanthes.—The present is a good time to start these terrestrial Orchids. They can be grown one pseudo-bulb to a 5-inch pot, or three to a 6-inch pot.

Coleus.—Although not so popular as they once were, many of the varieties are very beautiful, and should find some place in the conservatory during the summer months. Cordelia, with orange red foliage, is a lovely variety while in a young state. C. thyrsoides is also very attractive during winter with its plethora of bright blue flowers. Strike cuttings now.

Sweet Peas.—Autumn-sown Sweet Peas must get their final shift without delay, and have attention given to training them.

Fruits Under Glass.

Strawberries.—Plants whose fruit is swelling should be fed two or three times a week. Liquid cow-manure is excellent if used at moderate strength. A night temperature of 65° will suit this batch. Where the plants are in flower, great care should be exercised in admitting air, especially if east winds prevail.

The Hardy Fruit Garden.

Grafting.—This interesting operation is of some consequence to the private gardener from the utilitarian point of view. Those who have any intentions that way, should proceed with their work at once.

The Vegetable Garden.

Peas.—A sowing of some second-early variety should now be made. Royal Salute and Senator are both excellent sorts, the latter being a great cropper and only 2½ feet high.

Broad Beans.—A planting of some longpod variety should now be made, and I am partial to Bunyard's Exhibition, with its long, well-filled pods. Plant about six inches apart in the row and 2½ feet between the rows. A dash of wood-ashes sown into the drills helps the various leguminous crops.

Carrots.—A sowing of one of the stump-rooted varieties should be sown on a south border to succeed those sown in a frame.

Parsley.—This takes about six weeks to germinate, so that a sowing should be made as soon as convenient.

Potatoes.—Tubers which were started in heat a few weeks ago should now be hardened off in a cold frame preparatory to planting.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mans, Midlothian.

A NATIONAL DAFFODIL SOCIETY.

I CANNOT say that either the letters in THE GARDEN or any of those received privately have altered my opinion as to the suitability of establishing a National Society. I certainly do not write in any hostile spirit to the Royal Horticultural Society, nor yet to the Midland Society. I have seen the inner working of the former for a number of years, and I have come to the conclusion that it is out of its province to completely provide for the legitimate wants of the Daffodil people of the world. The supreme and only power is the Council. The Narcissus committee have no real authority in themselves.

Even the classification lists of 1908 and 1910 had to be submitted to the ruling authority before they could be issued. No money prizes for shows can be offered by the Royal Horticultural Society. This has had to be collected from people who, unless they happen to be members of the Narcissus committee, can have no voice in its spending.

It is everyone's business, I am told, to see to such things as the publication of a year book, the issuing of a schedule at the proper time, the recording varieties exhibited at shows, and such-like matters; but what is everyone's, I submit, is really no one's. As long as the supreme control is in the hands of an impersonal body like the Council, I do not see how it can be otherwise. They have not the driving power which is so absolutely necessary if the attempt is to be a success. The Midland Society has this in the person of Mr. Robert Sydenham. Its commanding position to-day is due to his personal efforts in a very large measure indeed, but the management is too local for it to take upon itself "National" functions, as few, except people who live in Birmingham and an half-an-hour radius by train, are ever present at the annual meetings.

Put in a very short form, my proposals are as follows: (1) A National Society to be formed, with the Royal Horticultural Society's Hall, London, as head-quarters. (2) The Midland to become "The Midland Branch of the National." (3) Each body to be independently managed and financed. (4) Subject to certain conditions, which would be settled by a joint committee of representatives of both societies—this to include such matters as date of shows, classification of varieties, deputations, publication of a year book—a floral committee to act at both shows for making awards to new varieties, &c. (5) A low minimum annual subscription for what might be called the Southern National. (6) The collecting a special fund to start the new society, and form a nest-egg for future use when required.

It is asked by certain growers, seedling-raisers and dealers if all this will help to sell bulbs. I think it will, and I instance the Perpetual Flowering Carnation Society under the able guidance of its chairman. The formation of a National Daffodil Society will enlarge the circle of supporters, as not every Daffodil person by any means is a member of the Royal Horticultural Society. Hence wider interest and an extended market not only for show (to take the more expensive kinds), but also for the garden (to absorb the cheaper ones).

Lastly, as everyone would like to see the volume of support which the new venture is likely to have,

might I ask those who are willing to support the proposal financially, and by becoming members, to kindly send me a post-card with their name and address.

JOSEPH JACOB

ROCK AND WATER GARDEN.

THE FIFTY BEST ALPINES FOR SMALL GARDENS.

IT requires a considerable amount of temerity to submit a list of fifty alpine and to assert that they are the best fifty for a small garden. Criticisms, some of them doubtless well founded, will arise, but it must be remembered that several considerations have had to be taken into account. In a small garden not only is the space limited, but an effort has to be made to prolong the display during as much of the year as possible, and a representation of the various classes of plants should also be included. Then, while the easiest subjects need not always be included, it is necessary to confine ourselves to those which are not among the really troublesome flowers. Most of the strongest growers are omitted, but Aubrietias, Phloxes and Arenaria montana

cannot be banished altogether. Exception may well be taken to the small selection of certain plants given here, but this is due to the necessity of affording as much variety as possible. Unless the owner of the garden is obsessed with his fancy for certain plants, he will be well advised not to make a collection of, say, Saxifrages, worthy though these are of our full consideration, but to cultivate alpine giving a more extended period of bloom.

It will be observed that a few bulbs are named, though the list of these might be greatly extended. For various reasons shrubs, with the exception of one or two, have been omitted. These and other omissions are due to reasons which seemed to the writer to be too powerful to ignore. It may be added with respect to the cultural notes and other information that sandy loam will answer for most of the plants named. Some like June, but all will do without it. In conclusion, it may be said that the list is submitted in no spirit of self-sufficiency, although it is founded on an actual experience of at least thirty years in growing alpine in the rock garden. This really adds to one's diffidence in furnishing it, owing to the full recognition of its many omissions—omissions which may to some appear unpardonable offences against their favourites.

Name	Height, Inches.	Aspect.	Soil.	Colour.	Flowering Period.	How to Propagate.

S. ARNOTT, Dontries.

HOT WATER AS AN INSECTICIDE.

OF all insecticides, water is the cheapest and, heated, is cleanly and effective. The summer before last the drought brought red spider on Apple trees, Gooseberries and other plants, and before the end of the season Vine leaves near the top ventilators were slightly affected. Last year it appeared on the same parts, and spread in a few days down the Vines. These were sprayed twice with perfectly clear water heated to about 180°, and this killed all the spider. "How about the fruit?" it may be asked. Provided the water is clean, no marks are left on the fruit, except here and there on the tip of an odd berry, and, if the foliage is clean, not even that. I have several times recommended washing bug-infested Vines with hot water. Some have tried it; others have been afraid to, though nothing is more effective for Vines in leaf. With the addition of a 3-inch potful of extract of Quassia to four gallons of lukewarm, not hot, water, it is a certain remedy for red spider on Peaches, and for both Vines and Peaches it is important to remember not to use strong insecticides. For aphids on Roses I like nothing better than soapsuds, into which some paraffin is churned with a syringe. A pint will do for a tubful, and this need not be applied hot.

I have once or twice had to deal with Camellias, Hoyas, Ixoras, Stephanotis, Crotons and other tough-leaved plants, which were filthy, not only with insects, but with dirt all over the leaves. In one case a man was kept constantly employed in the endeavour to wash the leaves of Camellias with a sponge and water, but he never seemed to make any progress. A thorough washing through an engine with very hot water, rendered more effective with soft soap in solution, brought off the dirt in scales, and, while moist, the rest was rapidly removed with a sponge. A proprietary wash I have found most effectual in destroying scale is Bentley's Insecticide. Sprayed, it goes a long way; but it is no use whatever spraying or washing with this or any other liquid unless enough is used to reach every part.

For destroying thrips, red spider and mealy bug on the majority of plants, nicotine vaporised is undoubtedly the best insecticide we have. It injures few plants, even when used much stronger than the several brands on the market are recommended to be used. The vapour finds its way where a liquid insecticide cannot, and though expensive, if carefully used—taking its effectiveness into consideration and the facility of its application—it must be allowed to stand at the head of all insect destroyers. What of hydrocyanic acid gas? It is true it is equally—perhaps in some cases more—destructive, but there is always a risk attending its use. Neither this nor nicotine can be used for Vines and Peaches in leaf unless at great risk to the foliage. Paraffin is also a dangerous material to employ unless one is thoroughly acquainted with the proper proportions to use, and usually, for Vines and Peaches, it should be dispensed with. I have found it most useful for destroying ants in vinerias. The method of using it is as follows: A pan is three parts filled with boiling water, and the paraffin added and stirred through the water till it is equally hot. All surfaces on which ants are found are then sprayed with the pure paraffin which floats on the top of the hot water, a few applications destroying strong colonies

of these destructive insects. An application of the same kind, applied while the trees are at rest, destroys American blight on Apple trees. Tobacco powder should always be at hand to destroy insects where circumstances render the application of either a liquid or vapour difficult or impossible. For Chrysanthemums in summer and for Carnations in beds, a pinch of this material is of very real value, applied at the right moment. I have found it very useful, too, for *Eucharis* mite, applied above the bulbs, moisture soaking it down between the scales. Last autumn our Cyclamen were severely attacked with a mite on the foliage and extended to the buds. Besides vaporising with nicotine, the buds have been repeatedly dusted with Tobacco powder, and except a few distorted blooms at the beginning of the season, all the later ones have come perfect.

After all, hand sponging cannot be entirely dispensed with. If there are no insects, there is still a certain amount of dirt that gathers on the leaves, and hand washing is therefore imperative. It is one of the curious facts connected with practical gardening that one finds almost all young men proceed in the same manner. They dip their dirty sponges into the insecticide or wash, and soon render it as filthy as, or more so than, the plants operated on. Now, the way to proceed is to have a somewhat large vessel with clean water, into which to wash the dirty sponge thoroughly every time before dipping it into the insecticide, and a sponge not too wet cleanses better than a saturated one. The insecticide, if the washing is done in this way, never becomes dirty. Some plants can be most effectively cleansed by spraying the leaves lightly over, then rubbed over with a large sponge or soft cloth, the process of cleaning these when soiled being the same as that just noted. Many house plants on which dust settles are best kept clean by rubbing frequently with a dry cloth.

R. P. BROTHURSTON.

CULTURAL HINTS ON NEW AND RARE PLANTS.

TREES AND SHRUBS.

Cornus Nuttallii.—American publications describe this Dogwood as one of the most beautiful objects in the forests of Western North America, for not only are the inflorescences conspicuous by reason of the six large, cream-coloured bracts which surround each head of flowers, but the foliage colours brilliantly in the autumn. To succeed with it in this country it is necessary to provide a sunny position in deep, well-drained, loamy soil.

Triacispidaria dependens, an evergreen shrub with pendulous white flowers which have delicately-fringed petals, forms an excellent subject for a wall. Planted in light, loamy soil with an east, west or south aspect, it may be expected to grow rapidly and give little trouble, save an occasional pruning. Cuttings root readily during the summer, and form a good means of increase. It must not be confused with the red-flowered *T. lanceolata*, which is sometimes called *T. dependens*.

Decaisnea Fargesii is a bushy plant from China, conspicuous on account of its long, pinnate leaves, greenish yellow flowers, and violet, sausage-shaped fruits. It may be expected to thrive in the milder parts of the country if given a sheltered position and light, well-drained, loamy soil.

Hamamelis mollis.—This is the best of the Witch Hazels, for the flowers are larger, clearer

coloured and borne more freely than those of other species. Although usually grown as a bush, it may be made to assume a tree-like habit by judicious pruning. The best results are obtained by planting it in light, loamy soil, into which a little peat has been mixed.

Cotoneaster humifusa may be distinguished from other *Cotoneasters* by its long, trailing branches, which rise but an inch or so above the ground. This peculiarity fits it well for planting about rockwork or to cover an upturned tree butt, for the branches take root wherever they come in contact with a little soil, and spread rapidly over a considerable area. Its evergreen leaves and red fruits are its chief attractions.

Stachyurus præcox.—Although this early-flowering shrub has been known for many years, it is rarely grown, yet when covered with its pendulous catkins of yellow flowers in March it is very attractive. It requires a light, well-drained soil in an open position where the branches can become thoroughly ripened in autumn.

BOOKS.

Crops and Methods for Soil Improvement.*—Books on farming and gardening come thick and fast, some dealing with particular plants, many little better than recipe books, a few dealing with principles. The present volume belongs to the last group, and deals with the basis of all commercial cultivation—the method of maintaining the fertility of the soil. It deals with large cultures, more for the farm than the garden proper, but many of its chapters will prove suggestive to the thoughtful gardener. It preaches the gospel of lime in the first place, and insists upon the need for lime in all ordinary cultures. We are continually meeting with cases in which lime is deficient in the soil, and the latter acid in consequence, the result being poor growth of the more commonly-cultivated crops and the encouragement of many of the more common insect and fungus pests. Clear accounts—and, indeed, the whole book is marked by lucidity of expression—of the forms of lime, the quantity to be applied and the time of application follow the demonstration of its need, and then the question of organic matter in soils comes under discussion.

We would like to have seen a little more concerning the use of green manures other than those of a leguminous nature, but probably their use is greater in the garden than on the farm, where the land would otherwise be lying fallow for a longer period than it does in the garden. In this country gardens are likely to suffer considerably from the increase of motor traction; indeed, the difficulty of obtaining stable manure is already keenly felt in many districts, but green manuring with such rapidly-growing plants as Mustard will help very much to fill the gap caused by the shortage of stable manure.

A chapter on the sources of the necessary nitrogen, potash and phosphoric acid will also be of value and interest to gardeners, while the discussion of crop rotations will also be most suggestive to the grower of vegetables.

We cannot close this brief notice without a further reference to the author's clear style and the freedom of the book from unfamiliar technical terms; but the omission of an index is a drawback not by any means compensated for by the full table of contents at the commencement of the book.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artists or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will always be recognised as acceptance.

NOTES OF THE WEEK.

New President of the Royal Horticultural Society.—We understand that Field-Marshal Lord Grenfell of Kilvey, G.C.B., G.C.M.G., F.R.S.A., has been invited to become President of the Royal Horticultural Society in place of Sir Trevor Lawrence, Bart., who, as we stated in our issue of February 15, feels compelled to relinquish the position on account of failing health. We believe that Lord Grenfell is likely to accept the invitation.

The Caucasian Scabious.—Before the planting season is over, we would draw attention to this useful and beautiful herbaceous plant. For cutting purposes during the late summer and autumn months it is ideal, the long, slender stems, with their delicately-posed, pale blue flowers, lending themselves well to artistic arrangement. Given good soil in an open position, it is not at all a difficult plant to grow, and it can be bought cheaply under the name of *Scabiosa caucasica*.

Black Currants Reverting to Wild Type.—When looking over a large plantation of well-grown Black Currants in the Malvern district a few days ago, the owner told us that he was considerably troubled by bushes reverting to a useless or almost wild type. This reversion had reached rather serious dimensions, and the only remedy was to dig out such bushes and plant others in their stead. Perhaps growers in other districts can give us their experiences with this fruit.

The Golden Valerian in Spring.—The golden-leaved Valerian, *Valeriana Phu aurea*, is not much seen nowadays, but it is useful in spring because of its foliage effect. It is much brighter at that season than later, and many years ago one was much struck with the effect it made in a long herbaceous border, where it was associated with *Orobus vernus*, then in bloom, and with the young growths of the *Heimerocallis*, *Tradescantias* and *Primas*. Here the golden leaves of the Valeriana made a really fine display.

Growing Sphagnum Moss for Orchids.—It is obvious that sphagnum moss which can be procured fresh must possess far better qualities than that sent out for sale after having been kept in sacks for at least several weeks. Where Orchid-growers have a shallow depression which will hold water, says a writer in the current issue of "The Orchid Review," it is quite easy to grow one's own sphagnum. It does not require running water, but likes to have it standing at an even height, it possible a few inches below the level of some Willow clumps, around which it will grow in the greatest profusion. It seems to like shade, direct sunshine on it during the summer months turning it yellow; but, providing water is kept round it, not much harm will be done. The planting of a new bed in the first instance is by no means difficult, and if a general autumn follows, an astonishing amount of growth is quickly made.

Silver-Leaf Disease of Plums.—This fungus is spreading rapidly in many of the fruit-growing districts in this country, and is causing serious loss among Plum trees, the variety Victoria seeming to be the most susceptible to its ravages. It is difficult to understand how it is spreading so rapidly where trees are well tended, because scientists tell us that spores can only be produced on dead wood. Is it possible that some stage of its life-history has been overlooked? Its presence in a tree is manifested by the foliage taking on a silvery grey tint.

Repotting Room Ferns.—Towards the end of March and during the early days of April is the best time of the whole year for repotting ferns that are grown in the dwelling-house. Just at that time root growth is becoming very active, and the new soil is quickly filled with roots and stagnation thus avoided. Good soil for ordinary kinds of Ferns is composed of well-decayed, fibrous turf two parts, one part sweet leaf-soil or coarse peat, and half a part of coarse sand or grit. The loam should be pulled into pieces about the size of pigeons' eggs, and ought to be kept in a warm place for a day or two before repotting. The new soil must be made quite firm when repotting, and thorough drainage and cleanliness of the new pots are essential.

The Tenerife Broom.—A specimen of *Cytisus proliferus*, the Tenerife Broom, is at the present time an important feature in the Himalayan House at Kew. Planted out in one of the borders, the growths are trained to, and clothe, one of the several pillars of this house to a height exceeding 12 feet. A native of Tenerife, *Cytisus proliferus* is occasionally seen thriving well outside in the warmer parts of the South and West. Those who have bare pillars and walls to furnish in large conservatories will find this Broom a most useful climber. Flowering in early spring, the plants respond to liberal pruning after flowering, making young growths up to 3 feet or more in length, which hang gracefully from the pillars wreathed in creamy white blossoms disposed among the ternate leaves.

An Evergreen Bush Honeysuckle.—Under the name of *Lonicera nitida* a valuable evergreen Honeysuckle of recent introduction from Western China bids fair to become permanently established in our gardens. Introduced by Messrs. J. Veitch and Sons, Chelsea, through their collector Mr. E. H. Wilson, it has already received an award of merit from the Royal Horticultural Society. *Lonicera nitida* forms a neat, compact bush, with small, upright shoots clothed with little Box-like leaves, their general appearance suggesting a small-leaved evergreen *Veronica* rather than a bush Honeysuckle. It roots readily from cuttings, and, growing freely in most soils, *L. nitida* should soon be widely grown in borders and as a specimen for the rock garden. In Western China the bushes are said to ultimately attain a height of about six feet; the flowers are creamy white and fragrant.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Crocus candidus sulphureus.—A yellow variety of the charming *Crocus candidus* seems rather a novelty, but we have it in the variety *sulphureus*, which I owe to the kindness of Mr. E. A. Bowles. It is a handsome *Crocus* of good size and with plenty of substance. It is hardly properly called *sulphureus*, as with me, at least, the colouring is considerably deeper than sulphur. It is not only pretty in itself, but is interesting as showing the great range in colouring which exists among the *Crocus* species and their varieties.—S. ARNOTT.

A Good Dwarf Shrub.—I was particularly struck last summer with the beauty of *Gemsta tinctoria flore pleno*, a compact and dwarf-growing shrub, which bore its yellow flowers in the greatest profusion. It grows about twelve inches high and appears to thrive in almost any soil or situation, for I saw it both on the rockery and in a border of herbaceous subjects where the soil was quite a heavy loam. It is undoubtedly a very attractive and bright little plant, which is free-growing, and will thus form a nice spreading patch in a short time. There is also a single form of *G. tinctoria*, but I should certainly select the double variety.—S.

The Colour of China Asters.—Is there any hope that seedsmen may be persuaded to name correctly in their catalogues the colours of the Asters they offer? At present nothing could be more foolish, misleading and exaggerating. When they are fairly correct as regards other flowers, why do they go so much astray when describing Asters? I have suffered in silence, hoping against hope year after year that by selecting carefully (!) named colours, such as blush pink or royal purple, my garden might not be wrecked on the magenta rocks. Last year I made one more attempt. I chose white streaked faint lavender, and white streaked light flesh. How I tended and cared for the little seedlings and watched their growth, and with what joyful expectancy I waited for the first flowers! Alas! I had border after border of Asters white with hard bands of violent purple or pinky magenta. The effect was appalling. If I order a pink coat from my tailor and he sends me a magenta one, I can return it. Why could I not return my nightmare Asters? The whole thing is extremely vexatious. I can see no reason why proper colour names cannot be given to Asters as to other flowers. Is it that seed does not come true, or that seedsmen are colour-blind?

E. M. HADDOX

The Tiger Lily in Pots.—The Lily that we have had in THE GARDEN of late has been particularly interesting to lovers of this beautiful, but in some cases erratic, class of plants. Reference to the forms of the Tiger Lily recalls the fact that all the varieties are not of equal value for growing in pots, a mode of culture which for business reasons I was forced to adopt a few years ago. It was very necessary to have a group of Tiger Lilies in flower at about their normal period of blooming, but they were required to be established in pots. For this method of treatment the variety *splendens* proved much superior to any others. As I have seen different forms bearing the varietal name of *splendens*, it may be as well to say that the one referred to is that grown by the Dutch for very many years, sometimes as *splendens* and sometimes as *Leopoldii*. It differs from the type in several particulars, for the lower

part of the stem is quite smooth and almost black; next, the leaves are fewer in number, but broader and of a deeper green, while the flowers are larger, brighter in colour and with fewer spots. These are, however, larger than in the other forms. Under pot culture the variety *splendens* retains its leaves very much better than any of the others, the very woolly-leaved *Fortunei* being, under this mode of treatment, liable to get bare at the base. The variety *flore pleno*, though the best example of a double Lily that we have, is not to my liking.—H. P.

The Red Cup Moss.—The pretty scarlet fungus known popularly as Red Cup Moss, the botanical name of which is *Peziza coccinea*, is one of the loveliest of the common objects of a country walk in the winter-time. It may now and again be found in the hedgerow, but never in quantity, for growing as it does on rotten wood, it is only where this occurs in abundance that it is at all common, and the most likely spot to find it is in an old wood or spinney where the ground is moist. In one place, close to the road, where an old plantation is never touched from year to year, it is to be found annually in the winter-time in great numbers on the damp ground, the little red cups glowing on the dark wood in dozens. Few, perhaps, are aware what a delightful and lasting indoor decoration this Red Cup Moss will provide if it be only artistically arranged. The scarlet fungi should be carefully taken up, each with the little piece of wood to which it is attached adhering to it, and cautiously carried home in a basket. A shallow dish or china saucer should be obtained and partially filled with water. Sufficient fresh Moss should be placed in the saucer to fill it, this being of a rough and not close-growing description, the so-called Fern Moss, a *Hypnum*, being the prettiest that can be procured. A couple of dozen fungi, if the saucer is large enough, these ranging in size from half an inch to 2 inches across, will afford a charming and uncommon decoration for the living-room during the depth of the winter, and will retain their colour and freshness for a month or more.—WYNDHAM FITZGERBERT.

Primula denticulata.—I heartily agree with your note in THE GARDEN for February 15, page 77, relative to the above and its variety *cashmeriana*. The soil of my garden being very light, I have found it difficult to get a spot sufficiently moist for the summer months in any border, yet during the winter the wet has caused the crowns of the plants to decay, and I shall have to start with a fresh stock. Can you suggest any method of cultivation which would obviate the loss of such beautiful spring-flowering plants? Could they be lifted in the autumn, placed in 5-inch pots in a cold frame and flowered effectively therein?—HIMALAYA. What is really needed is that the plant be afforded some covering in imitation of the deep snow covering of its native home. For this we know of nothing better than a mound of new Coconut fibre, which is at once light, warm and protective. In conjunction therewith the soil should be well drained, despite the fact that the species is of a moisture-loving nature. In winter it cannot utilise the moisture, hence the trouble. With the shelter of a wall and in light, sandy soils heavily dressed with cow-manure, we have grown this in Northern gardens to far greater perfection than is usually attained by treating it as a bog plant. Hence you might try lighter soils and afford the above covering for some while, potting up others in September and giving them cold-frame treatment. We imagine you will

get the finer heads of flowers from the undisturbed plants. The plants should be so covered up while perfectly dry early in November. The covering should be cone-shaped to throw off wet. At the end of February it should be removed.—ED.]

An Uncommon Greenhouse Plant (Amphicome Emodi).—This greenhouse plant is said to succeed on the rockery if protection from wet and severe frosts is afforded. It is, however, usually seen as a pot subject, and its bell-shaped, rose and orange flowers are produced from July to October. Overpotting must be guarded against, and a compost of loam, leaf-mould and sand will be found most suitable. At the present time cuttings made from the young shoots may be inserted in sandy soil and placed in gentle heat, where they will soon root, and if judiciously potted on will form nice flowering plants in a comparatively short time. Seed can also be sown in well-drained pots or pans during the months of March and April, and if arranged in the greenhouse, germination will soon commence. *Amphicome Emodi* belongs to the Natural Order Bignoniaceae. It is rather dwarf in habit and is of a perennial character.—S.

The Flowering of Fruit Trees.—No one can help admiring the exquisite beauty of the white and rose petalled branches of our fruit trees in spring; but they have another interesting phase to which I would draw attention, and that is the order in which they open their flowers. My observations extend over two successive years, but those of last year only are given, while my notes are somewhat restricted owing to the limited number of varieties under my charge, and also to the fact that both years I omitted to note several sorts of Apples. It is my intention to make notes again this season, when I hope to include the previously omitted kinds. In each case the date given is that upon which the first flowers opened. Jefferson's Plum, March 24; Archduke Plum, March 27; Coe's Golden Drop Plum and May Duke Cherry (both growing on a fence), March 31; Victoria Plum, April 2; Czur Plum, Transparent Gage Plum and Archduke Cherry, April 4; Empress Eugénie Cherry, April 6; Pear Williams' Bon Chrétien, April 7; Pear Doyenné du Comice, April 14; Morello Cherry, April 11; Catillac Pear, April 15; Apples—Irish Peach, April 18; Lord Suffield and James Grieve, April 21; Potts' Seedling, April 22; King of the Pippins and Flower of Kent, April 23; Worcester Pearmain and Cellini, April 24; and Lane's Prince Albert, April 25. A comparative perusal of the above varieties and dates will disclose the fact that all early varieties do not open their blossoms before some of the late varieties begin to do so. To the writer, at least, this seems rather strange. One would naturally think that the earliest fruits to mature would be the first to hasten into blossom; but it is not so, apparently, with Apples and kindred fruits. On the other hand, the varieties of Strawberries, Currants and Gooseberries do, so far as I have been able to watch them, open in their order of coming to maturity. Has any other reader ever made like observations, or can anyone suggest a reason for the above methods being followed? Of course, the actual dates on which the flowers open each year will vary, depending chiefly upon four factors, namely, the earliness or otherwise of the spring, the warm or cold nature of the soil, whether grown in the open or a shaded position, and early or late pruning; but these conditions would not affect the order of varietal flowering in any given garden.—C. TURNER.

A Noble Fern.—I send you a photograph of a very handsome Fern, *Aspidium angulare acutilobum* (the Soft Bricky Shield Fern), grown in a beautiful garden in Surrey, at Whitmoor House, Sutton Park, near Guildford, belonging to Philip Witham, Esq., where I often visit, and which garden I helped to remake. The Fern now measures 6 feet across and 3 feet 6 inches in height, and is quite the finest specimen of the kind I ever saw. It was originally growing on an old and badly-constructed rockery close to the house, which was done away with some six or seven years ago, and planted in its present position by the edge of a walk leading to the tennis courts and herbaceous borders, in a kind of semi-wild garden. The position and soil evidently suit it, as it has more than trebled in size.—C. M. WOLSELEY, *Wolseley, Stafford*

Lachenalias, or Cape Cowslips.—I call these always my February flowers. Writing in the early days of the month, I am daily watching my precious treasures colouring and opening. As usual, the famous old Nelson and Rose Barton lead the way, but some of the red edgers are just showing, Ruby, Brightness and Phyllis Paul among the number. This year my patience is being rewarded in a handsome manner. I am about to enjoy what their great high priest, Sir Frederick Moore, has been doing for a long time—that is, the gradual unfolding of a number of my own seedlings. In dwarf pots the best varieties look splendid, and they are so good for bringing into the dwelling-house, as they last a long time in bloom, and if they are grown "coolly" the spikes need no support. After my late awful attempt at classical Latin, and profiting by "G. H. E.'s" wiggling, I am taking refuge in a more doggy style, and say to those who want a flower of much quiet beauty and of great interest, "Growiendia est Lachenalia."—J. JACOB.

The Servian Spruce.—An interesting fact about the Servian Spruce, *Picea Omorica*, is that, though a native of Central Europe, no evidence of its existence is recorded until 1875. It is a native of the mountains of South-West Servia, Bosnia and Montenegro, growing at an altitude of from 2,000 feet to 5,000 feet. Several trees raised from seeds received from Belgrade in 1880 are bearing cones at Kew. These are 1½ inches long, rather less than half an inch in diameter at the broadest part, and borne near the top of the tree. In its native country the Servian Spruce varies from 50 feet to 100 feet in height. The largest trees in this country are from 30 feet to 35 feet high. Compared with the height of the tree, the branches are short, giving the tree a pyramidal outline. A large number of trees are growing at Kew in varying stages from a couple of feet upwards, the tallest tree, twenty-four years old, being about thirty-two feet high. The behaviour of these trees suggests that, particularly considering the atmosphere of Kew, *Picea Omorica* will be a valuable decorative tree for extensive planting. It is one of the flat-leaved Spruce Firs, its nearest allies being *P. ajanensis*, *P. hondoensis* and *P. sitchensis*. In some books the specific name is spelt *P. Omorika*.—A. O.

THE HEATH GARDEN.

PROPAGATION OF HEATHS.

(Continued from page 110.)

PROPGATION is effected by seeds, cuttings and layers, the former being only practised in the raising of hybrids, although self-sown plants of the common Ling are to be found in great quantities on the hills and moors of Britain. A favourable seed-bed for these is, however, only found after a quantity of Heather has been burned off and the ground rendered bare of vegetation for a time. As is well known, where large tracts of Heather are found on grazing land, a portion is burned off annually to provide a succession of fresh young shoots as food for sheep and grouse, but when, for the want of sufficient draught to enable the fire to consume the plants rapidly and pass on before the heat has had time to destroy the roots, the slow combustion may destroy all life and render it necessary to procure

always a few plants in reserve. These should be planted or laid on their sides with the shoots buried up to within a few inches of the tips; when left thus for a year or eighteen months, fresh roots will have been produced from the hard stems, and young plants or tufts of a convenient size for replanting will be easily secured. In replanting the beds with young plants it will not be necessary to entirely renew the soil; the addition of some well-decomposed manure will generally be found sufficient, well mixing it with the compost. Top-dressing the beds annually with stable manure is found of great advantage to the plants; this should be secured, if possible, where the stalks or boxes have been bedded down with moss-litter. A little of the material taken fresh from the stable and shaken among the plants during their season of growth will well repay the trouble by assisting the production of strong, healthy growth and abundance of flowers.

Selection of Varieties. In making a selection of varieties, one must be guided by the extent

A BEAUTIFUL HARDY FERN, *ASPIDIUM ANGULARE ACUTILOBUM*, IN A SURREY GARDEN.

a crop from self-sown seeds, the process is, however, slow, and several years must elapse before it again becomes good seeding ground.

Propagation from cuttings is also slow, but is a successful enough method if carried out with sufficient care. The cuttings should be selected from half-ripened shoots of the current year's growth and placed around the edges of pots filled with a sandy compost. After receiving a good soaking of water they should be placed in a cold frame or under a bell-glass, secure from frost until rooted.

Layering.—The most satisfactory method, however, of increasing the stock of hardy Heaths is by layering, as this can be done in the open, unless where the soil is unsuitable, in which case a cold frame may be utilised, filling it to sufficient depth with a light, sandy compost.

As all the *Ericas* are liable after a few years' occupation of the beds to become leggy or straggling, replanting with fresh dwarf plants becomes necessary, and for this purpose it is a good plan to have

of ground to be treated, by the climate, and whether spring or autumn flowering varieties are most desired. The most interesting selection, however, would be one in which all varieties are represented and planted with a view to having the beds flowering in succession during the greater part of the year. Where a number of beds can be conveniently arranged, each should be planted with varieties flowering about the same time, in preference to having them filled with many sorts flowering at different periods. The grouping of colours should also be carefully studied along with their comparative heights, commencing with those that flower early in the year. A large bed might be devoted to *Erica multiflora*, *E. codonodes*, *E. carnea* or *herbacea* and its varieties. *Arborea*, under favourable circumstances, will grow to a height of from 4 feet to 6 feet, and, indeed, sometimes attains to the dimensions of a small tree. This plant is said to provide the wood from which the so-called hair-root pipes are made, and is largely imported from France to this country.

for that purpose. It may form the central figure of a large bed; the flowers for the most part are white, although several varieties in different colours are recorded. *E. lusitanica* or *codonodes*, occasionally known as *E. polytrichifolia*, closely allied to *E. arborea*, is also a tall grower, reaching a height of 4 feet; this is a most beautiful variety, with white flowers borne very profusely, and having foliage of a pleasing soft green. *E. multiflora* is, perhaps, the earliest to show flower, producing its blossoms of a pale red colour sometimes in the last weeks of December, if the weather at that time is at all favourable. Its average height is about two feet, and is well adapted for planting between the first two named and the dwarf varieties of *E. carnea* with which we would finish the planting of the early bed. *E. carnea* forms dense tufts of pink flowers, and rarely exceeds a height of 6 inches. It is one of the freest, both in growth and flower, of the whole genus, and should be included in every collection. *E. c. alba*, often catalogued under the name of *E. herbacea*, is of slightly dwarfier

compact grower bearing red flowers; this variety requires somewhat closer planting than the others to enable it to cover the ground properly and avoid a certain stiffness in form that it assumes when given too much room. *E. m. hybrida* has somewhat larger and brighter individual flowers on shorter stems, and usually flowers were early, particularly in the southern counties. *E. m. rubra* might be described as a deep pink; *E. m. nana* and *E. m. stricta* both being red. The first four named should serve for most purposes, except where a very full collection is desired. F. WILSON.

(To be continued.)

ROCK AND WATER GARDEN.

THE "MULCHING" OF ALPINES.

In many parts of this country alpine flowers suffer greatly from the want of moisture at

of something which will not only ward off the scorching winds, but will serve as a non-conductor and keep the plant free from excessive changes of temperature, and will at the same time retain moisture. If we can attain this object, and also prevent the plant from receiving injury from excessive rains in winter, we shall overcome many of our greatest difficulties in the cultivation of certain flowers.

The moraine is almost magical in its effects in this direction, but it is not everyone who can have one, although small and simple moraines can be constructed at very little expense. We can, however, give nearly all the benefits of the moraine by mulching our plants with small chips or gravel, or, almost as well, with some rough grit. It is many years since the writer learned from actual trial how beneficial a thing was a thick mulch of the rougher grit from the seashore close to where he lived. With 1 inch or 2 inches of this about the plants, it was wonderful to see the benefits which resulted. Troublesome subjects were much easier to grow, and many easy things were still easier to accommodate, when so mulched with this material. Small chips, such as are now so much employed on roads, are every whit as good, and the mulching may be from 1 inch to 3 inches or even 4 inches in height. An excellent mulch is composed of a combination of the chips and the grit, and its application is followed in many cases by results which are perfectly surprising. Plants which suffer from the drying spring winds are protected at the roots by this material, with its "layer" of air between the stones. Any rain which falls, or any water artificially supplied, runs freely through the mulch and is conserved when it reaches the soil. In times when there is an over-supply of moisture, the parts of the plant which are most liable to rot off are saved by the dry chips about them; and all those which require glass protection, *i.e.*, such subjects as some of the silky *Androsaces* and other things with woolly or very hairy foliage are much benefitted.

This mulching with chips or gravel may be applied at any time, and in the case of low-growing, carpeting subjects it is wise to add it gradually, so as to allow the plants time to grow up among the mulching material, and not to smother them by too thick a layer at once. This "mulching" is simplicity itself, but it is most efficacious. OLD ALPINIST.

SAXIFRAGA GRIESBACHII.

This is a plant all alpine specialists are anxious to grow well, but it rarely thrives up to one's expectations in the gardens of this country. It was introduced to cultivation ten years ago, when it received a first-class certificate from the Royal Horticultural Society and created quite a sensation among the rock gardening community. It was at first thought likely to become a popular subject for the rock garden, but many have found to their disappointment that such is not the case. Now and then, however, one alights upon a garden where it succeeds fairly well. Its greatest enemy is damp, and it appears to give the best results when grown upon a small cone of stones in a sunny position. The plant illustrated is a particularly good specimen, carrying no fewer than five healthy inflorescences. Each rosette develops into a flower-spike, the calyxes and flowers being bright crimson, and, after flowering, young rosettes appear at the base of the flowered crown. *Saxifraga Griesbachii* is a native of the mountains of Albania and Macedonia, and is one of those cherished plants requiring more than ordinary care.

A PLANT OF *SAXIFRAGA GRIESBACHII* WITH FIVE FLOWER-SPIKES

dimensions than the former, but otherwise an exact counterpart in all but the colour of the flowers, which are white. When grown in quantity these lovely little Heaths provide some of the earliest storage for bees, and together with the tall varieties, already named, give a display during the first three months of the year; but before they have quite gone out of flower other varieties are rapidly coming forward. During the period from March to May, *E. mediterranea* in numerous colours will serve to keep up the succession, and several beds may be devoted to this section. The type grows almost three feet high, and has flowers of a pleasing shade of red, and should be planted towards the centre of the bed or well back from the margin of the border; the others, being mostly of a uniform height of from 6 inches to 12 inches, according to the suitability of the soil and climate, may be disposed in patches or blocks to fill up the beds according to the ideas of the planter. *E. m. glauca* is distinct in habit, being a very

the roots during their growing season, and, on the other hand, from too much surface wet at times when they should be at rest. In spring, especially when the parching "March" winds (which, of course, do not always come in the month which gives them their name) lick up every drop of moisture and leave the plants thirsting for the genial rains of the spring, many of these alpine flowers suffer enormously. Often carelessly planted and in uncongenial conditions, they miss the moisture supplied at home from the melting snows, and, alike above and below ground, have much suffering and trial to endure. It is easy to realise the vast difference between the plant growing in the moist soil of the mountain-side with its roots constantly supplied by the melting snow, and the same flower on a dry rockery subjected to the parching winds of some of our springs.

This condition may be mitigated by the roots being singly tucked away under or between stones, but there is nothing so good as a thick "mulching"

THE FRUIT GARDEN.

THE APPLE-SUCKER.

HOW FRUIT TREES ARE ATTACKED: BRIEF LIFE-HISTORY OF THE PEST

THE apple-sucker (*Psylla mali*) is certainly one of the most destructive pests of the orchard. The particular object of its attack is the bud, which it enters immediately the awakening life in spring sufficiently expands the protecting scale leaves to enable it to crawl inside. At this period the tiny creature—a flat, dirty yellow larva (A) with bright red eyes—has just hatched out from the egg, being one of hundreds of others laid the previous autumn on the young

RUPTURED EGG-CASE OF PSYLLA—LARVA ESCAPED (ENLARGED TWENTY-FIVE TIMES).

shoots and fruit-spurs of the tree. Once inside the bud, it feeds by stabbing the delicate tissues, and by suction of the nutritive juices of the young leaves seriously interferes with their normal development. Leaves so attacked (especially if the larvae are numerous) partially lose their healthy green colour, and become pale, shrunk and curled. The vitality of the leaves is lowered, hence their power to manufacture starch is reduced, and this in turn lessens nutrition and weakens the seasonal growth. But bad as this is, it is not by any means the end of the trouble. For so soon as the flowers begin to push out from the bud, the larvae are able to attack the soft, sappy tissues of the lengthening

peduncles (or flower-stalks) and to so injure them that they fail to transmit the necessary food and water, and then, of course, the blossoms wither and die and all chance of fruit is gone for the season. The dead flower-trusses will hang on to the spurs for a long time, and a very large number of gardeners wrongly attribute the damage to late spring frosts, and thus fail entirely to recognise the presence of these dreadfully destructive little pests. The rest of their life-story is soon told. After two or three moults the larvae gradually pass into the nymph stage (B); they grow a little bigger, their colour changes to green, and wings gradually develop, until finally, in late May or early June, they become transformed into first green and then variegated winged adults, from one-tenth to one-eighth of an

THE WINGED OR ADULT PSYLLA (ENLARGED TEN TIMES).

inch in length. In this stage of their existence they are apparently harmless. Towards the middle of September and until about the beginning of November the females begin to lay their eggs, selecting for this purpose the hairy surfaces of the youngest twigs, the leaf-scars round the bases of the lateral buds, and particularly the rough surfaces of the fruiting spurs. The eggs are minute, but, still, they can be easily seen if searched for. They are oval in form and securely fastened to the twig by means of a glue-like material.

Treatment of Trees to Prevent Attack.—The aim of the fruit-grower in his treatment of trees attacked by *Psylla* must be mainly, if not entirely, directed to prevention of entry to the bud, for the reason that once the larvae gain an entrance, there is considerably less chance of arresting the damage or otherwise effecting a cure. Attempts should, therefore, be made to destroy the eggs, or to at least prevent the escape of the young larvae from the shells. There is a real difficulty, however, in this. The shells that serve as a protection to the otherwise exposed ova are of a peculiar horny nature, and only a strongly corrosive wash can penetrate them; and a solution of sufficiently effective strength is just as likely to damage the tissues of the tree as to destroy the eggs. There seem to be good grounds for the belief that the method originally advocated by Mr. Hammond (whose extensive Essex experience as a fruit-grower is well known) is the best course to take in grappling with the difficulty. Mr. Hammond's wash was a solution of a mixture of quicklime and salt, made as follows: Slake half a hundred-weight of *freshly-burnt* lime in a small quantity of water. Then add it to 100 gallons of water,

A

B

LARVA OF PSYLLA (ENLARGED FIFTY TIMES)

NYMPH OF PSYLLA (ENLARGED FIFTY TIMES).

Stir well and strain off to separate all particles of grit. To this thick lime-wash add 20lb. of dissolved salt and thoroughly mix. Theobald recommends the addition of from 2lb. to 5lb. of water-glass to this solution, explaining that by so doing the adhesive power of the wash is usefully increased. In spraying, the object in view is to thoroughly cover the eggs with a lime-salt paste, and so increase the difficulty of the newly-hatched larvae to escape. A special nozzle is almost essential in spraying this rather thick fluid, as clogging is frequent during the operation. The special form of nozzle known as the "Seneca" has been recommended, as it is provided with an arrangement for rapidly clearing the aperture without unscrewing the nozzle; but other types to meet such cases are now on the market.

This is the principal method of prevention, but there are others that may be adopted as supplementary in severe cases. For example, Mr. Pickering recommends that the above work might be usefully followed by spraying with a decoction of Tobacco at the time of the bursting of the buds. The object of this particular spray is to kill any larvae that succeeded in escaping, before they have time to reach the young flowers. This, if successful, will save the fruit. The strength of decoction suggested is that of two parts of strong Tobacco in a hundred parts of water. Suitable nicotine washes for the purpose can, however, be readily obtained from reputable vendors of insecticides. It will be safest and best for amateur fruit-growers to take this latter course. C. O. Hinge strongly recommends spraying the trees with a paraffin emulsion in the autumn, when the winged females are hibernating among the branches and

SPURRED SHOOT OF APPLE TREE IN WINTER, SHOWING ATTACHED EGGS OF PSYLLA

SHOOTS OF APPLE TREE IN SPRING WITH NEWLY-HATCHED-OUT LARVAE OF PSYLLA WAITING FOR BUDS TO OPEN.

engaged in egg-laying, and in large orchards the practice has much to commend it. An attempt at the eradication of this ruthless enemy of Apples is a work that ought to be at once undertaken through the co-operation of all gardeners and fruit-growers in the country. Unlike most other members of the aphid family, its only known food plant is the Apple. This fact gives an enormous initial advantage to the exterminator. Keep the insects off the Apple trees in a sufficiently wide area, and they will become extinct by starvation in a generation or two within that area. The difficulty, of course, in all such troubles is to secure effective simultaneous action. D. Houston.

[The illustrations used in connection with the foregoing article are after Theobald, from blocks kindly lent to us by *Irish Gardening*.]

THE FLOWER GARDEN.

LILIUM GIGANTEUM IN CORNWALL.

THE accompanying illustration represents the best bed of this noble Lily that we have ever seen. Good individual plants are not uncommon, but it is seldom that a whole colony can be induced to flower at one time. The illustration is from a photograph kindly sent us by Major

SWEET PEA NOTES.

A QUESTION which is perplexing many lovers of Sweet Peas is whether or not their favourites are losing ground in general esteem. The streak disease has been so prevalent and so widespread that many people are becoming disheartened, and it will not need many additional failures to cause them to exclude the plant from their gardens, as far as the production of exhibition blooms is concerned. Happily, when plants are grown to yield blossoms for cutting, the plants do not suffer to nearly the same degree as those more highly cultivated with a view to big blooms on long stems, while the old-fashioned, smooth varieties certainly appear to enjoy immunity in large measure, presumably because they are of stronger constitution.

A further fault that tells against the modern race is the lack of perfume; but perhaps some raisers will spare time from their Mendelian studies to remember the old fragrance which was so penetrating and yet so delightful, and will endeavour to find us fresh colours in which it is present in full measure. Given this and healthy plants, the Sweet Pea can never die.

This is the great month for outdoor sowing, and notwithstanding the thousands of seeds sown indoors in the autumn and spring, far larger quantities are sown out of doors in March and April. Endeavours have been made to persuade

is no doubt that the results will be sufficiently good to admirably repay the efforts made.

If the chosen position has not been dug since it was originally prepared and manured, forking over to a depth of 10 inches or so must be done at once, as time for settlement must elapse before the seeds can be satisfactorily sown. Where it has been impossible to dig and manure the ground earlier, do the work instantly, and tread sandy soils hard down prior to seed distribution. In all instances where flowers for the home are wanted, it is unwise to use natural manure to excess, as infinitely superior results follow upon moderate dressings, with supplements of one of the several valuable concentrated foods offered by advertisers in the pages of *THE GARDEN*. If the plants are to be grown in rows, a distance of not less than 6 feet should separate them.

For the reception of the seeds, shallow drills should be cut, and the base ought to be made firm and level. As a rule, a depth of 2 inches suffices; but in light soils a little deeper may be wise, while in heavy land rather less is to be preferred. The seeds must be set 3 inches apart, and later, when the seedlings are through, thinning should commence and continue until the plants are 6 inches or 9 inches asunder.

It is wise to provide protection against birds, and there are excellent devices on the market,

or guards of wood and string can be made at home. Slugs, too, will demand a toll unless they are kept in check, and for the purpose frequent dustings with either old soot or lime are reliable; but the frequency of dressing must be allowed to vary with the weather, more applications being wanted in wet than in dry weather. Constant pricking over of the surface is also most advantageous in checking the ravages of the slimy foe. Twiggy sticks must be put to the plants before they are 3 inches in height to prevent the possibility of falling over. J. R.

A BOLD PLANT FOR THE WATER-SIDE.

(*SENECIO CLIVORUM*.)

OF the numerous plants introduced from China within the last decade or so, it is questionable whether any one of them is more firmly established in the gardens of this country than *Senecio Clivorum*. It is a large, coarse-growing subject, and unless given ample room is calculated to smother surrounding vegetation, and for this reason it is not a desirable plant for the herbaceous border. But for planting in bold groups in a fairly open woodland, wild garden, or, better still, by the water-side, it is quite well adapted. In the illustration on page 123 it is seen in association with the large-leaved *Gunnera manicata*, growing by the lakeside in Gunnersbury House Gardens, and this is a congenial home for both of these robust plants. *Senecio Clivorum* has roundly peltate leaves 2 feet or more in diameter, the branching inflorescence attaining some 4 feet or 5 feet high. The flower-heads are numerous and large, the colour being rich orange. The plant is quick to develop, quite hardy, and of striking appearance when in flower. It is interesting to note that it belongs to a vast genus—probably the most extensive in the vegetable kingdom.

A BEAUTIFUL BED OF LILIUM GIGANTUM IN A CORNISH GARDEN.

G. T. Williams of Manor House, Burton Joyce, Nottingham, and the plants were grown in his garden at Tredrea, Perranwell, Cornwall, in 1911, which was his home at that time. Major Williams informs us that there were twenty-three stems bearing flowers in the bed at the time the photograph was taken. We are much indebted to him for allowing us the opportunity of recording and illustrating such a beautiful bed. We hope other readers who may have interesting photographs will follow his example. By so doing a permanent record is made of many beautiful plants that would otherwise be unnoticed by the majority of flower-lovers.

growers that success is only possible when sowing under glass is done, but this is absurd. Until recent years the seeds were wholly sown where the plants were to flower, and, when the space in and between the lines was abundant, many thousands of superb flowers on splendid stems were produced; and if they were not as big as those seen at present-day shows, they were unsurpassable for the decoration of the house and garden. Amateurs who love Sweet Peas must not have the slightest hesitation about sowing in the garden. If the soil has been thoroughly prepared in advance, the seeds are thinly sown in suitable drills and the plants are correctly managed throughout, there

THE ROSE GARDEN.

SOME UNCOMMON ROSES.

THE many interesting notes that are written about the newer varieties prompts me to write a few lines about those that are now all too little grown in the rush for the more modern sorts. Many of the older varieties have much to recommend them if they are given even moderately good treatment. For covering walls, those I name are really useful. I do not claim for them that they are perpetual flowering. From my knowledge of the newer varieties, some of which are claimed to be continuous flowering, I cannot yet see that any appreciable advance has been made in that direction. Flower of Farneld is said to be an improvement on the older Crimson Rambler, from which it is a seedling, but I am afraid the continuity of flower only extends to a few straggling late shoots that develop flowers in due course.

Gloire de Dijon is certainly perpetual flowering as new growth is made, but even this old favourite cannot be termed a really good Rose for covering a wall, as it has such a habit of becoming bare at the base, also for a considerable way up the wall.

Reve d'Or was introduced by Pernet-Ducher in 1860, belonging to the Noisette class, and for a south wall it would be difficult to find a better variety. In growth it is vigorous, producing a huge crop of deep yellow blossoms which contrast well with the dark-coloured foliage. Where so many err in the cultivation of this Rose is in not pruning it correctly. Many persons leave the whole of the last season's growth to flower, and although a quantity of blooms are produced in this manner, they are ill-shaped and poor in colour; the spring growth does not appear to be vigorous enough to develop the flowers perfectly. The correct method of pruning when the wall is covered with main branches is that all subsequent shoots should be closely spurred in yearly, and from the new growth will come the much-prized blooms in quantity and quality.

Cloth of Gold (Coquereau, 1843) is another variety almost lost sight of, and although this does not flower so abundantly as the former, the individual quality is so extremely fine that one does not notice the lack of quantity.

Celine Forestier (Leroy, 1858) on a south wall is a charming Rose, the pale yellow blossoms being almost extravagantly produced in clusters.

Lamarque (Marechal, 1830) is one of the oldest Roses we have belonging to the Noisette class, and for freedom of flower it would be difficult to find a superior. Out of doors the colour is very pale lemon; under glass, pure white. In growth it is rampant, but the more the vigour the greater quantity of flowers produced, and well into the autumn, too. A system of close annual pruning is desirable. This is a Rose that succeeds on its own roots.

Aimee Vibert (Vibert, 1828) is an almost ever-green variety, quickly making a thick wall covering

and producing its pure white, sweetly-scented flowers in huge quantities.

Ards Rover (A. Dickson, 1898) is a much better climber than many persons seem to think, as it is so seldom seen in this form of growth. The late Mr. Flight of Twyford, Winchester, who was an ardent rosarian, knew the virtue of this Rose as a wall plant, and by closely spurring it in yearly he had an abundant flower crop annually. For richness of perfume and brilliant colouring this is a charming Rose.

Bouquet d'Or (Pernet-Ducher, 1872) is an improvement on *Gloire de Dijon*, in that its flowers are more freely produced and individually of

how long an established plant on a south or east wall will continue to give huge crops of flower. I know of one of the yellow type, over seventy years old with a huge stem, which even now gives its annual quota of flowers.

Swainmore.

E. MOLYNEUX.

THE CABBAGE ROSE.

WHAT a name to bestow upon such a fragrant Rose! Why Cabbage? Its appellation is generally accepted as derivative from "Cabuche" or "Cabus," which are the Cabbages and Cabbage Lettuces of France. Of course, it is generally

SENILIO CLIVORUM EFFECTIVELY GROUPED BY THE WATERSIDE AT GUNNERSBURY HOUSE, ACTON.

better quality, with a little more copper colour in the centre.

Reine Marie Henriette (Lewett, 1873), commonly known as the Red Gloire, is deserving of attention where an early bit of bright wall colouring is required, as this Rose gives its cherry red flowers abundantly. Prune closely.

Isabella Sprunt (Verschaffelt, 1867) will grow 20 feet high and annually give a huge crop of its lemon yellow flowers, which continue in a lessened manner throughout the summer and autumn.

Sinica Anemone is worthy of a place on a south or west wall, where its large silvery pink, single flowers are produced freely, and which contrast so well with the darkly-tinted foliage.

Belle Vichysoise produces its violet pink flowers in clusters early in the season and again in September, when it is most valuable on that account.

Marechal Niel I hardly care to mention, as it seems to have almost dropped out of cultivation as an outdoor variety. Anyhow, given a south wall and liberal treatment to plants worked on the ordinary Briar, magnificent blooms can be obtained, also a wealth of foliage.

I have left the Banksian type till the last, but cannot exclude them, although they have one serious fault—want of continuity. It is surprising

known that the Cabbage Rose belongs to *Rosa centifolia*, but where it originated is not definitely known. Some authorities say one thing, others another. It is rather remarkable that hybridisers have not taken this tribe in hand more, because undoubtedly it is very amenable to cross-fertilisation. It is very sportive, one lovely variety, the Crested Provence, having originated as a sport from the Cabbage Provence, and first noticed on the walls of a convent in Switzerland. I have heard of plants of the Cabbage Rose known to have been in one family for eighty years. Others have related how, on transplanting rooted cuttings from one garden, the plants have sported and produced single blooms.

The Moss Rose is generally believed to have sported from the Provence Rose, and was first introduced from Holland to England some 500 years ago. Now in the Mosses there is a far larger variety than in the Cabbage or Provence Roses. I am certain one could evolve a very fragrant group of Roses from both of these tribes, and I should say it is worth while. One of the sweetest Roses I know is Zenobia, a large-flowered Moss variety, but with very little of the mossy characteristic, and yet it is unmistakably a Moss. I value fragrance so much that I think I would rather have a fragrant

variety that flowered but once than a continuous bloomer that is scentless. That the Moss Rose is able to impart its mossy character is proved by the new hybrid with wichuriana in the variety named Wichmoss; and now that raisers have made a start to use the tribe, let us hope we may soon have other beautiful hybrids from these groups. DANECROFT

TREES AND SHRUBS.

THE DOUBLE-FLOWERED CHINESE CHERRY.

(*CERASIS SERRULATA FLORE PLENO.*)

THIS exceedingly ornamental tree is too well known to need description, for its profusion of double white flowers suffused with pink make it one of the greatest pleasures of the garden in April. The tree makes a fine head with its widely-spreading branches, and for this reason it is

trees and shrubs. Yet in the few instances where the hybridist has gone systematically to work, he has achieved results which are quite equal to those which have crowned his efforts in other directions. Moreover, the several natural hybrids which have occurred among woody plants rank so high in their respective groups that there would appear to be every encouragement offered to the person who takes up the hybridisation of trees and shrubs on an extensive scale.

Everyone is familiar with the gratifying results which have rewarded the efforts of the raisers of the garden Roses, Rhododendrons, Azaleas, Clematises and Syringas, and in a more modest way of the Diervillas, Philadelphuses, Magnolias and Deutzias; yet in each of these groups a great deal of work is still to be done. With the many new Rhododendrons which have appeared during recent years, particularly with those of a dwarf character, it is likely that quite new types could

further efforts, while the popularity and general usefulness of the hybrid *Berberis stenophylla* suggest the Barberries as a likely field for work. Within the last twenty years we have had ample proof of M. Lemome's success with the two genera *Philadelphus* and *Deutzia*, while his garden Lilacs may be found by the dozen; but in each genus there is still considerable work to be done, for there are numerous species yet unworked which suggest themselves as likely parents.

There is already a number of hybrid *Spiræas*, but with such a one as *S. arguta* as an object-lesson the hybridist may well push the work further. *Cotoneaster* is an untouched genus, yet it appeals to one as a likely family to produce interesting results. With the exception of *Hypericum moserianum*, no hybrid *Hypericums* have appeared; yet, although the various species do not cross readily, they should be persevered with. The new kinds of *Clematis*, more particularly the varieties of *C. montana*, crossed with older kinds might be made the parents of a distinct race with the *montana* habit, while the beautiful *C. Armandii* is quite worth trying as a parent. Among hardy Heaths there is a floriferous hybrid, *Erica Veitchii*, raised between *E. arborea* and *E. lusitanica*; but what one would like to see would be the union of the tall-growing Southern European sorts with the hardier *E. carnea*. Whether these species are too widely separated to cross must be considered, but in hybridisation one must take chances and be prepared for a goodly percentage of failures.

Isculus carnea, the red-flowered Horse Chestnut, is a worthy example of a large-growing tree of hybrid origin, and it is probable that others quite as beautiful could be raised in the same genus. The various hybrid *Pyruses* are showy enough to warrant further efforts among the species, while such a genus as *Catalpa* might furnish useful trees. It is only during a very hot summer, however, that the last-named genus would be likely to perfect seed. The few hybrid forest trees which have appeared are generally more vigorous than their respective types, and sylvicultural experts look forward to the time when hybrid trees may be grown as well as, and more rapidly than, species. Except with those subjects, such as Willows and Poplars, which may be raised from cuttings, the day seems far away when hybrid trees will be able to compete successfully with species for forest planting—not, at any rate, until types can be obtained which will breed true from seeds.

Altogether there would appear to be a remunerative future for anyone who takes up the hybridising of trees and shrubs in a systematic manner, although he must be prepared to wait several years before he can hope to see any return for his work. One thing is, however, highly essential to the success of such an undertaking: that is, that strict records are kept of all the work done, not only the actual crossing, but the sowing of the seeds, appearance of the plants, their behaviour in regard to growth and their time of flowering.

W. D.

A BEAUTIFUL SPRING-FLOWERING TREE: *PRUNUS SERRULATA FLORE PLENO.*

an admirable subject for planting as an isolated specimen on a lawn in such a position as that depicted in the accompanying illustration. Although the cutting of specimen trees is by no means recommended, yet this double-flowered Cherry is one of the most useful for room decoration, a few sprays, each wreathed with its little rosettes of flowers, having a most charming effect when arranged in large bowls or Japanese vases. Trees of this beautiful Cherry may still be planted, but the work should be completed at the earliest possible date.

HYBRID TREES AND SHRUBS.

As yet the hybridist has played such an important part in the horticultural world by the raising of new types, or the improvement of existing kinds, of fruits, vegetables and many of our showiest decorative plants, except in the case of a few genera very little work of a systematic character has been carried out in connection with

be raised, especially if such a showy and floriferous plant as *R. racemosum* were used as one parent. The large-flowered Chinese kinds, again, crossed with Hindayan or American species, or with existing hybrids, would probably produce really good varieties, while the several yellow-flowered kinds which are now obtainable are well worth using as parents in order to try to obtain a large-trunked, yellow-flowered evergreen.

Two or three species only have been used as parents among the Magnolias, yet there are many others which might be tried. *M. stellata*, for instance, offers decided possibilities, while the summer-flowering kinds also deserve attention. More will doubtless be done with the *Diervillas*, yet, while the new genus *Dipelta* may possibly prove quite as amenable as the closely-allied *Diervilla*.

The few hybrid *Brooms* are showy enough and distinct enough to encourage the hybridist to

GARDENING FOR BEGINNERS.

HOW TO RAISE ANNUALS.

WELL-GROWN annuals bear such a profusion of beautiful blossoms, and are so varied and rich in colours, that every year amateurs extend their cultivation considerably, and there are many additions to the ranks.

There are the half-hardy and the hardy annuals. The flowers of the latter are as beautiful as those of the former, but the half-hardy kinds and varieties must be raised under glass or given some temporary protection. Amateurs possessing every convenience as regards glass structures—especially in the form of heated frames—may sow seeds several weeks earlier than those persons who are obliged to depend on cold or temporary frames.

Raising Annuals Under Glass.—This may be done in pots, pans, boxes, or on the bed formed in a frame. The actual sowing of the seeds is best done in pots, pans, or boxes. Where great quantities are required, boxes may be used in which to sow the seeds, as the inexperienced cultivator is not so likely to sow them too thickly. It is, however, a good plan to prepare a number of pots, pans and boxes in good time, also the compost; then the work of actual sowing can be quickly done.

All seed receptacles must be clean, especially inside, and well drained. In springtime the sun-heat is strong and the soil dries up quickly on the surface. If the drainage is bad, then the soil will soon become sour through the frequent applications of water. The general compost for the seeds sown under glass should be made up of the following ingredients: Old fibrous loam passed through a half-inch sieve, sweet leaf-soil (both of the above in equal proportions), some rotted manure (1 peck to 6 pecks of the above), and coarse sand or road grit. This will do nicely.

HELPFUL ILLUSTRATIONS IN SELF-SOWING AND PRICKING-OFF ANNUALS. FOR FULL DETAILS SEE TEXT.

The larger seeds may be sown in the coarser compost, but for the very tiny ones the soil used may be again sifted. There is no difficulty experienced in sowing the larger seeds with the hand, but the finer ones may be sown as shown in Fig. A at No. 1. The seeds are placed in a "scoop" formed of half a sheet of note-paper, or even a smaller piece, as shown at No. 2. It is very easy then to distribute the small seeds thinly and evenly. Very tiny or dust-like seeds should be scattered on a white surface formed of sand; then the sower can readily see how thickly the seeds are dropping.

Favourite positions for seed-boxes are the front stages of greenhouses over the hot-water pipes, as shown at No. 3, or on the higher shelves. Over-dryness must be guarded against. When seeds are sown in pots, the latter should be well drained and not be more than three parts filled with compost, as shown at Nos. 4 and 5.

Harden, and even raise, many seedlings in cool frames, as shown at No. 6. No. 7 shows a seedling of Marguerite Carnation ready for the first transplanting, and No. 8 the same plant ready for a second transplanting. No. 9 shows a Helianthus seedling before being transplanted, and No. 10 the same plant seven days afterwards. These will act as guides for an inexperienced amateur as to how the young seedlings must be treated right from the beginning.

How to Raise Annuals in the Open Border.—These should be of the hardy kinds, or, if of half-hardy ones, very early sowing must be avoided. Prepare the soil by deeply digging it and putting in some rotted manure at the same time, and before sowing the seeds well break up the surface.

Whole Borders of Annuals.—Fig. B shows how to arrange annuals in a border near a fence. Nos. 1 1 1 1, Mignonette; Nos. 2 2 2, Godettias; Nos. 3 3 3 3, Stocks (some mixed colours, others distinct); Nos. 4 4 4, Sweet Peas; Nos. 5 5 5 5, Collinsia grandiflora; Nos. 6 6 6, Candytuft (some mixed, others distinct); No. 7, Coreopsis-Burridgei (crimson and yellow); No. 8, Clarkia elegans Brilliant; No. 9, annual Chrysanthemums (mixed); No. 10, Lupinus roseus. Fig. C shows a long, narrow border, tile-edged, with the annuals grown in rows. No. 1, Stocks; Nos. 2 2 Asters (mixed colours); Nos. 3 3, Tom Thumb Nasturtium Beauty of Malvern (rich scarlet). Of course, other kinds may be used; this is simply an example given as a guide. The Nasturtiums are best in poor soil.

HOW ANNUALS MAY BE ARRANGED IN NARROW BORDERS AND NEAR FENCES.

G. G.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Lobelia cardinalis.—This showy subject should now be commencing to grow, and to secure good plants the old clumps should be pulled apart, placing one, two, or three shoots in a 3-inch pot. A little heat may be necessary to give them a start, but after they get nicely rooted they may again be returned to the cold frame.

Clematis Jackmanii should now be pruned hard back, and if the plants are in such a position that the roots are among or under other shrubs, a good dressing of well-rotted manure will help them considerably. Attention must be given the plants as they break into growth, tying up the young, tender shoots regularly, or many valuable flowers will be lost.

Lawns.—The unusually mild weather has been the cause of keeping the grass growing practically all the winter, and in sheltered positions it has attained a good length; but now that there should be no danger from severe frost, mowing must be commenced. Where very long, the scythe must be requisitioned; but where only of moderate length, a light machine, such as a "Pennsylvania," will be the best to use. Needless to say, a good sweeping and rolling a few days beforehand is necessary to get the lawn to look well after cutting, and I never think it wise to set the machine too low for a start.

The Rock Garden.

The various subjects in the rock garden are now growing apace, and the present is a good time for making up any deficiencies. Propagated plants of last season may now be planted out without any fear of injury from frost, as we ought not to get very severe frosts now.

Top-Dressing.—After a year's rain such as we have had, many of the niches, crevices and pockets in the rock garden will be the better for the addition of a little soil, after forking over the surface with a small hand-fork, good leaf-soil and fresh loam being probably the best dressing for most subjects, though in others a little peat or, maybe, limestone chippings will be found more suitable to the requirements of individual plants.

Plants Under Glass.

Cannas.—Stock plants of this useful greenhouse subject should now be shaken out, potting up the young rhizomes singly or two or three in a pot, according to requirements. For flowering on single stems in a 4½-inch or 6-inch pot, a 3-inch or 4-inch pot will be best for the present, while those intended for larger pots or for planting out may be potted two or three in a 6-inch pot. A fairly rich, open compost is best for them, and a brisk growing temperature will ensure them making roots quickly.

Freesias.—Where these are grown on from year to year, they should be given fairly liberal treatment. Now that they are all out of flower, they should be placed in a batch in a fairly cool house or frame and given liquid manure-water till growth is matured, when the manure-water may be gradually withheld as the foliage turns yellow, and the bulbs be given a good drying off in the sun before shaking them out of the soil.

Alocasias.—These are now breaking into leaf, and should be reported before growth is very far advanced, or the plants will receive a check. Good fibrous loam, peat, charcoal, sphagnum moss and silver sand is a good compost for them. Where the rhizomes have attained any great length, the bottom may be removed, just keeping the crown well above the surface of the soil. The old stem, if cut up and placed in sand in the propagating-frame, will readily increase the stock. Plenty of heat and moisture are required for these plants, and the shady side of the stove will suit them best.

The Kitchen Garden.

Seakale.—The present is a very suitable time for planting the things that have been prepared beforehand and which may have already formed small shoots or growths; and to secure good forcing crops for the autumn a well-cultivated and richly-manured piece of ground should be selected. Plenty of space should be allowed between the rows, and the sets placed from 9 inches to a foot in the rows. These should be well firmed by treading,

keeping the crown of the thong (or cutting) just on a level with the surface of the soil.

Radishes.—Weekly sowings should now be made out of doors, at the same time making another sowing in the frame to keep up the supply till the outdoor ones come into use.

Potatoes.—Early varieties may now be planted on warm borders, but only where the soil is naturally light and dry. Tubers that have been started in boxes will naturally be selected for the purpose; but if the growths have attained any great length, they must be planted at a depth where they will not come through the soil too early.

Fruits Under Glass.

Early Vines.—Many of these will now be advanced enough for thinning. If a good set has been secured and there are more bunches than are required, they may be taken off before thinning is commenced, and thus save time and labour, though, where young hands are employed in thinning, it may be advisable to leave on more than is required, in case one or two happen to be spoilt. Generally speaking, early varieties of Grapes do not require quite so much thinning as do the later varieties, but to secure good berries a fair amount of space is required. Many bunches are spoilt by over-thinning of the shoulders, or top branches of the bunch, thereby losing weight as well as shapeliness of the bunches.

Feeding.—Immediately after thinning is an excellent time to give the Vines a good manuring, either in the form of liquid manure or artificial sprinkled on the surface and watered in, and at this time a good, quick-acting manure is far the best, as most growers will have dressed the borders either in the autumn or winter with the slower-acting phosphatic and potash manures.

Ventilating.—To take full advantage of all the sun-heat, great care must now be exercised, and though a temperature of from 60° to 65° may be sufficient if it has to be maintained by fire-heat, a very considerable increase may be allowed with the sun. THOMAS STEVENSON.

(Head-gardener to F. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Border Carnations.—These may be planted as soon as the condition of the soil will permit. Taking it for granted that the ground was previously manured and deeply dug, it should now receive a dressing of soot and ground lime, and then be loosened and made fine with the digging-fork. Allow the soil a few days to settle, and then plant with a trowel about fourteen inches apart either way. Carnations are most effective when considerable masses of a variety are planted together. A dusting of soot when the foliage is damp will help to keep the sparrows at bay.

Iris reticulata.—This Iris is a gem, and as it is now in bloom, it suggests to one to advocate its cultivation on a more extensive scale. With bulbs at sixpence apiece and the certainty of their increasing rapidly, there is no reason why it should not be every man's flower. It is partial to a good supply of moisture if drainage is ample, and it likes a little peat.

Gладиoli.—The finer named varieties of these may now be started in a greenhouse temperature, either in 4-inch pots or in boxes among some light, flaky material.

Tuberous Begonias.—These should now be started in a little heat. Place them in shallow boxes on a layer of flaky leaf-mould, and work in a little of the same material and sand between the tubers, leaving the crowns bare. Spray lightly daily to induce them to push, but beware of giving them too much moisture.

The Pleasure Grounds.

Trimming Edgings.—This work should be attended to before dry weather sets in. Prior to applying the edging-iron to the edgings of lawns and grass walks, the roller should be run along the edge of the lawn twice, and when edging no more should be pared away than is absolutely necessary to ensure a straight edge. Where

curves have to be negotiated, see that the line describes a graceful sweep before commencing to cut. Where long, straight lines occur, the line should be pegged down at regular distances.

Pruning Ivy.—This is an ideal time to prune ivy, just before active growth commences, as it then remains bare for the shortest possible period. Here we use a sharp hedge-bill for the operation, as by means of it the work can be done more expeditiously than with the pruning-shears; moreover, with this tool one can reach points difficult of access when the shears are used.

Plants Under Glass.

Rooted Cuttings.—Cuttings which were inserted a week or two ago will now be rooted, and should be potted off. Give a good watering when potted, but afterwards be sparing of water at the roots till growth again commences. Spray lightly in the afternoons and keep rather close for a time.

Gloxinias.—The main batch may now be started into active growth much in the same way as recommended for tuberous Begonias, but in a rather higher temperature.

Chrysanthemums.—Early-struck stock intended for the production of large blooms will now mostly be fit to shift into 5-inch pots, and the following mixture will be found suitable: Two parts of fibrous loam, one part of good leaf-mould, one part of dried horse-manure, with some sand, soot and bone-meal added. Keep the plants well up to the light in a cool house.

Fruits Under Glass.

Disbudding Peaches.—Some of the later houses will now require attention, and two general principles should be observed—remove buds occurring above and below the shoot for preference, and utilise the buds occurring near the base of the shoot as far as possible.

Potted Trees.—These, whether in an orchard-house or other structure, must be artificially pollinated as they come into flower. A fine feather brush or a rabbit's tail serves the purpose very well. The operation should be performed in the early forenoon. Maintain a rather dry atmosphere at this period and apply no stimulants till the fruit is set.

The Hardy Fruit Garden.

Fighting the Birds.—Bullfinches often do considerable damage to the buds of the Black Currant, and tomtits play havoc with the buds of the Gooseberry and Red Currant. A dusting of soot or slaked lime will generally ward off their attacks till the critical period is past.

Magpie Moth Caterpillar.—When the sawfly caterpillar appears, a dusting of Hellebore powder will annihilate the enemy. Not so with the pest under consideration. This too, however, can be exterminated, and that by spraying either with arsenate of copper at the rate of half an ounce to twelve gallons of water, or arsenate of lead at about eight times the strength indicated. Which ever is used, get it in paste form, and add some treacle to the mixture to make it adhere. Stir frequently during the process of spraying. If there is any suspicion of the presence of the pest, the bushes should be sprayed now.

The Vegetable Garden.

Planting Early Potatoes.—Tubers which were started in a little warmth may, if the weather is mild, be planted out at the foot of a south wall, and should be partly covered with some old potting soil in a rather dry condition. This batch will be of limited size, and will require to have protection afforded it should hard weather occur. The bulk of the early varieties should also be planted whenever the conditions of soil and weather will permit. A good tilth should be secured, and the drills be drawn 2 feet apart with the draw-hoe. A dusting of soot in the drills will be beneficial. Plant the sets about a foot apart. Midlothian Early and Duke of York are two excellent early varieties.

Parsnips may now be sown in ground that has been deeply trenched and has had no rank manure applied to it. Those who are to grow for exhibition would do well to pierce the ground deeply by means of a stont-pointed, round stake and mallet, filling up the holes with sifted rich soil. Sow a few seeds in each hole and thin out to one plant later.

CHARLES COMFORT.

**HINTS ON PACKING
DAFFODILS FOR A SHOW.**

BETWEEN the growing and the staging of our blooms there is a very important operation to be performed, viz., their transference from our own home to the venue of the show. I have been asked to give some hints as to the best way of packing the flowers for this journey.

One of my earliest recollections of Daffodil shows is the arrival of the late Mr. Bourne on the scene at Birmingham with an innumerable number of small boxes that might very well have contained chocolate creams or slabs of nougat, but which, as a matter of fact, were full of very carefully-laden Daffodil blooms. At that time my own flowers used to be brought in the more rough-and-tumble way of just bunching up the different kinds together and then crowding them into boxes *rather tightly*; much, in fact, in the same way as I would pack for market. This worked pretty well. The flowers were too close together to move, but when they were taken out they showed traces of their crushing, and it was long before they completely recovered. A few never did, although they were always some time in water before they were staged.

Material Required.—Nowadays I never pack like this. What I do I am about to explain step by step. The stock in trade from which I draw consists of (1) suitable-sized boxes made of quarter-inch light wood with the ends and bottoms of half an inch to give strength. They must be deep enough to take the longest trumpet. Width and length are more or less optional. A convenient size is: Depth, 4½ inches or 5 inches; length, 33 inches; and width, 12 inches; but in this matter everyone must please themselves, only let them be *deep and long* enough. All the boxes should be exactly the same size for the convenience of tying them together in twos or threes when travelling. (2) Half-inch common white tape; (3) small drawing-pins; (4) white tissue-paper; and (5) some raffia or other tying material.

The First Step is to give all our flowers a good drink. From ten to twelve hours is none too long. Then, before packing, they should be carefully drained and the ends wiped to avoid any liquid oozing out, as has happened to the long stem in the illustration. The box must be lined with paper, and enough left to fold over the flowers when the box is full. I secure the tissue-paper to the bottom by a pin in each corner. As a rule, every bloom is packed singly by securing its stem in two places (sometimes in three), as shown in the partly-filled box. Sometimes, however, it is best to tie three or four together, as is done with the "eyed" flowers. These are secured in a similar way to the bottom of the box. To steady individual flowers I frequently find it advisable to place cushions of crumpled tissue-paper behind them (see the right-hand flower, where such a pad can be plainly seen). These must be firmly pinned to prevent

their working loose. The pieces of tape must be cut long enough to leave a free end to take hold of when the pinning process is completed. Unpacking is thus facilitated, as the pins can be drawn out without any breaking of finger nails, and in consequence, possibly, some not very polite language. The illustration shows only a partly-packed box; but both ends must be utilised for the blooms, leaving the centre for the stalks. With a little practice it is very surprising how many may be got into a box by carefully interlocking, as it were, one flower with another. Space is valuable, as obviously no one wants to take more boxes than are

needed. These, together with some nice fresh green moss, should be in a box by themselves. I always take rather more than I think I will want. In the end I generally use all I have; one can hardly ever put too much foliage in the vases. On the other hand, it is an eyesore to come across blooms set up with too little. In conclusion, may I give this further piece of advice to those who are not adepts at taking flowers to show: Be sure to practise before the exhibition box is to be packed. The interlocking of the blooms into one another, no less than the firm pinning of the stems with the pieces of tape, requires a certain amount of familiarity with the process if it is to be done well. JOSIAH JACOB.

A USEFUL BOX PACKED WITH NARCISSUS READY FOR TRAVELLING TO THE SHOW.

absolutely necessary. If the journey is a very long one, small sponges or wedges of damp brown paper may be introduced among the stems (of course, well secured) to keep the inside atmosphere moist and so preventing the perianths from flagging.

On Arrival at the Show it is hardly necessary to say that the boxes should be unpacked as soon as possible. If there is enough time, about a quarter of an inch of each stem should be cut off with a sharp knife before the blooms are put into water. This undoubtedly aids its absorption. An important adjunct to good flowers is having *plenty* of

WINTER FOLIAGE FOR CUTTING.

JUST now, when flowers are scarce, it may be of use to note some of the kinds of hardy greenery that are available for indoor decoration, with the addition of very few flowers, or even without any. I do not grow many shrubs with parti-coloured foliage, but should not like to be without a bush or two of the gold-variegated *Elaeagnus*. Not only is it handsome in itself and highly becoming to any white or yellow flowers, but two or three short pieces of branch, from their extremely stiff and rigid character, make a convenient support for the flower-stems. It is also durable, lasting well for a fortnight or even three weeks. Every winter, just before Christmas, it comes into special use to accompany a few spikes of *Cypripedium insigne*. The gold-variegated *Privet* is another favourite and a good companion to the yellow Winter Jasmine. Another shrub with a golden effect, though not variegated, is *Cassia fulvida*. The small leaves are dark green above and yellow underneath, but from the set of the branches, so much of the yellow shows that it has a general golden effect. As a garden shrub its defect is a weak habit, the long, yearly shoots hanging out in a way that makes a rather ragged-looking bush. A free cutting of these outer shoots not only provides greenery of a refined and unusual appearance, but helps to keep the shrub in better shape.

Alexandrian Laurel (*Ruscus racemosus*) is a slow-growing plant, but the owner of a few well-established tufts may well spare a frond or two for room ornament, and it lasts so long that the sacrifice is the less regrettable. In a room one can all the better admire its incomparable grace and structure. The same may be said of the Sweet Bay. It is a strange thing that one does not see a Bay tree in every garden. It may be a little too tender for our colder regions, but should be grown wherever the climate allows. As in the case of the Alexandrian Laurel, the beauty of form is an unending wonder and delight, and can best be appreciated when it is brought indoors.

Earlier in the year *Hex* branches are beautiful with flowers, but by this time they are generally spotted and unfit for use. *Skimmia japonica*, and especially the wider-leaved forms *obovata* and

Foremanii, are among the best of winter greens for cutting. No leaves are so good for putting with Stephanotis, the twigs cut short and set in an open bowl. Stephanotis is not flowering yet, but Skim-mia branches, in longer pieces, are admirable with Lent Hellebores, as the flowers, whose inclination is to hang their heads, can be brought up among the stiff, leathery leaves and made to show their inner beauties. But the Hellebores will not last well unless the precautions are taken of slitting up the stems so that they can drink their fill of water, and of putting them overnight in a deep pail or something that will give them a bath of several hours' duration with the water up to the actual bloom.

Two of the Andromedas, namely, *Leucothoe Catesbaei* and *L. axillaris*, have beautiful and long-enduring foliage for winter use; some of it green and some marbled and spotted with red; some even red all over. There is scarcely need to remind anyone of the use of *Berberis Aquifolium*, with its fine colourings of reddish bronze. The almost equally familiar *Aucuba* with the yellow-spotted leaves is not so often used indoors as it deserves. G. JEVETT

ANSWERS

TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

HERBACEOUS BORDER (J. B.).—A border of the width and length you describe would be better treated with two lines of groups, together with low-growing plants at the margin. The Privet, both in the matter of colour and the hungry nature of its ever-spreading roots, is, to some extent, a drawback, though the colour may be obliterated by planting green-leaved subjects—*Galeras*, *Scheuchzeria palustris*, *Delphiniums* and other tall-growing subjects—in the background. In such a case, and more particularly if the Privet is inclined to colour much in summer-time, you should avoid planting white and yellow flowered things; good strong blues, violet, rose and mauve would be better. If the aim is to produce good effect quickly, you should plant three or five of every variety of plant to form a group, arranging the stems a foot or more apart according to their habit and vigour of growth. For example, a back line of groups set at least 2½ feet from the hedge might be made up of *Anchusa Dropmore* variety, *Aster Chimæa*, *A. William Marshall*, *A. cordifolius* ideal, *A. Arcturus*, *Hollyhocks* in rose, pink or red shades, *Phlox Flambeau*, *Delphiniums Duke of Connaught*, *Carmen*, *Persimmon*, *King of Delphiniums*, *Amos Perry* and *Galega His Majesty*. These would have to be distributed throughout the length of the border. In the second line of groups plant *Phloxes Iris* and *L. Mahdi* (blue shades), *Mrs. E. H. Jenkins* and *Sylphide* (white), *Etna* (crimson-scarlet), *Elizabeth Campbell* (pink), *Iris pallida*, *L. p. dalmatica*, *L. aurea*, *L. Queen of May*, *L. Gracilis*, *L. Mine*, *Cheerful*, *Pyrothrums* (single and double), hybrid *Columbines*, *Delphinium Belladonna*, *Trollius napellifolius*, *L. Orange Globe*, *Rudbeckia Newmanii*, *Erigeron Quakeress*, *E. speciosus* superbus and hybrid *Pentstemon*s; while near the margin *Phlox Tapis Blanc*, *Campanula carpatica*, *C. c. alba*, *C. c. Riverslea*, *Mossy Saxifrage*, *Aubrietia*, *Pinks* and other plants of like stature might appear. We cannot enter into the question of cost: the plants enumerated would cost from 5s. to 10s. per dozen. Your better plan would be to invite prices from the hardy plant specialists who advertise in our columns. Prices vary, naturally, according to the size and quality of the goods supplied. You had better allow the Currant bushes to remain, as, in any case, the fruit crop this year from recently-planted trees would not be much.

PLANTING BEDS WITH PERENNIALS (A. O. J.).—The borders on each side of the gravel path, by reason of their varying widths, will require somewhat different treatment. You might, however, observe some degree of uniformity by planting a margin of white *Pink* or *Dr. Jules Anrieta*, royal purple colour. Behind these for the larger border you might arrange *Campanula Hostii*, *C. H. alba*, *C. glomerata danubica*, *C. carpatica*, *C. c. alba*, *C. Riverslea*, *C. Hillside Gem*, *Helium pumilum*, *H. p. magnificum*, *Heucheras* in half-a-dozen sorts, *Arenaria plantaginea rubra*, *Aster sub-cærules*, *Primula japonica*, *P. denticulata* and *Saxifraga cordifolia purpurea*, in another row hybrid *Columbines*, single and double *Pyrothrums* in variety, *Flag Irises* in perhaps a dozen sorts, with *Campanula persicifolia* in blue and white, *Helium cupreum* and the like. If a few taller plants were needed, you would obtain them in *Michaelmas Daisies*, herbaceous *Phloxes*, *Delphiniums* and *Sundewers*. In the narrower border, apart from the margin, there would be room for two lines of plants, and you might for a start take half of the *Campanulas* named above and distribute them throughout the length of the border. By planting in the same line a variety of *Pentstemon*s, great gaiety would be secured, and to these could be added *Phlox canadensis*, *Trollius europæus* and *Aster acris nana*, in the next line a selection of white, blue and salmon coloured herbaceous *Phloxes*, *Iris pallida*, *L. p. dalmatica*, *L. aurea*, *L. Monnet*, *Aquilegia chrysantha*, *Trollius Orange Globe*, *Delphinium Belladonna*, *Aster Amellus* in variety, *A. acris*, *A. crivoides*, *A. c. Desire* and the like. In the lawn beds you had better rely on a few plants. *Aster cordifolius* ideal and scarlet *Pentstemon*s for the central bed, planting the other two with *Lilium speciosum* crimson and white and pink *Pentstemon*s. It is a little unfortunate that the beds are now occupied, as this will make the planting late. Had you arranged for planting in autumn, a variety of good garden Lilies and *Daffodils* might also have been included. If you have but little knowledge of the plants, some advice on the spot would appear necessary in order to secure an effective distribution of the plants.

TREES AND SHRUBS.

IS THUYA OCCIDENTALIS POISONOUS? (G. B. M.).—We have no evidence of *Thuya occidentalis* being poisonous to sheep or horses, and nothing to that effect is mentioned in any of the American publications we have seen. We think that if the tree were really poisonous, something to that effect would be mentioned in the botanical descriptions of the species. It has been in cultivation in this country since 1596; therefore there has been ample opportunity for such properties to have been noted, did it possess them.

PLANTING HEDGE NEAR A RIVER (M. M. C.).—It would certainly be unwise to plant a Yew hedge on ground that is subject to occasional flooding, for there would be little chance of the hedge succeeding. It is possible that *Whitethorn* might answer the purpose, but you would probably do better to plant common Alder, *Alnus glutinosa*. This does not mind the ground being wet, and may be kept fairly compact by strict attention to pruning. Be careful, however, to use plants which are bushy to the ground, otherwise the hedge will be gappy.

SHRUBS FOR A NORTH BORDER (C. E. F. M.).—The following shrubs are likely to thrive in the position you mention: *Berberis Aquifolium*, *B. wallenianum*, *B. stenophylla*, *Ribes sanguineum*, *For-sythia suspensa*, *Spiræa arguta*, *Cotoneaster Laxtonia*, *C. rotundifolia*, any of the *Privets*, *Anemba japonica* and *Escallonia philippiana*. It is rather doubtful whether a *Fuchsia* hedge would succeed in the position, but it is worth trying. Be careful to work the ground well before planting the shrubs, otherwise they will not start away well, and in such a position a good start is half the battle.

CLIMBERS FOR A HOUSE (Mrs. M. S.).—You cannot do better than plant *Crataegus Pyracantha* on the front of your house. It is evergreen, is easily kept within bounds by pruning, flowers well in May and bears showy orange-scarlet fruits in autumn. It is not a self-clinger, but needs little nailing, the main branches only requiring support. *Tropæolum speciosum* may succeed with you if your soil is cool and moist, but it must not be placed in a position where it will feel the full force of the sun. A west or north-west aspect is considered a good one for it. We do not know whether plants take two years to flower if grown from seeds, but it is quite likely that they do.

DISEASED LEAVES OF CAMELLIA (Rev. S. H. B.).—The leaf sent for examination has been injured by a fungus, but the plant from which it was taken must be in a very poor condition if the leaf forwarded is typical of the others on the plant. We imagine that the plant has become weakened by being planted in unsuitable soil. Probably it is badly drained and sour. A little good could be done by removing and burning the worst of the leaves, at the same time cutting the branches moderately hard back and burning the prunings. Then spray the branches once a week for a month or so with Bordeaux mixture or some other fungicide. Syringe with clear water two or three times a day, and as soon as new shoots appear take the plants out of the old soil, remove all the soil, drain the border well with clean bricks and clinkers, and replant in equal parts of good fibrous loam and peat, with a fair addition of sand, bits of sandstone and pieces of charcoal. The replanting could probably be done about the middle of April. There is little doubt that root injury is the original source of the trouble. In the event of the roots being found to be very bad, it would be advisable to destroy the plant and start again with a new one.

DECAY IN OAK TREE (O. M.).—It is not possible to say from the piece of wood sent for examination what may be the cause of the decay of the Oak. The section received is typical of what is often noticed in decaying trunks and branches which have been injured by fungus. The insects present in the wood are only such as inhabit dead wood, and they are not responsible for the decay. Your best plan is to cut all dead branches clean away, making the cuts parallel with the trunk. Then, where decayed places occur, clear away as much decayed wood as possible and paint the surface over with a strong solution of carbolic acid. When that is dry, give all wounds a coat of coal-tar, and where there are any hollows, fill them with cement level with the bark. When the cement is dry, it may be painted with tar to make it less conspicuous. Any of the topmost branches which may be dead should be cut down about a foot below the dead joints, the wounds being tarred over as advised for the others. If the tree is fairly vigorous, a considerable amount of new wood will be formed in the course of the next few years.

PLANT FOR NAME AND TREATMENT (H. C. N.).—The specimen sent for identification is *Acacia armata* variety *angustifolia*. It may be grown in pots or in a border in a cold or cool greenhouse, and in Cornwall and other places where similar climatic conditions prevail it may be grown out of doors. A good compost may be prepared by mixing peat and loam in equal proportions, with one part in seven of silver sand. Pot firmly and stand the plants out of doors in June, letting them remain in a sunny position until September, then removing them to a light and airy greenhouse. Plants grown in indoor borders may be given the same kind of soil, but care must be taken to provide good drainage. When the plants are well rooted, give manure-water twice a week during the growing season, for the object in view is the formation of long, strong shoots which will produce flowers throughout almost the whole length, and the plants must be grown without a check to effect this. As soon as the flowers are over, cut the shoots well back, thinning out any weak or useless wood, and give a little more heat and a closer and moister atmosphere until growth recommences. Any repotting required may be done when the young shoots are half an inch or so long. Cuttings of young shoots, about four inches long, inserted in sandy soil in a close frame, may be rooted in a few weeks' time. The young plants must be stopped frequently to induce a stocky foundation, and, as a rule, they are better if not allowed to flower until they are a couple of years old.

THE GREENHOUSE.

DATES ON WHICH TO STOP CHRYSANTHEMUMS (H. M.).—Treat the varieties as follows: *Countess of Granard*, *D. B. Crane*, *H. E. Converse*, *Lady Talbot* and *Lady Edward Letchworth* stop about April 20 and take the first-crown buds that show in August. They will appear from the 10th to the 25th of that month. *William Turner*, *Lady Francis Ryder*, *Thorp's Beauty* and *Mary Poulton* stop about the middle of April and again in the middle of May, and take second-crown buds which will show during the latter part of August. *F. Chandler* and *Hon. Mrs. Lopes* should be stopped on April 20 and first-crown buds taken. The variety *Mrs. Gilbert Drabble* should be stopped during the last week in March and first-crown buds taken; these will not show too soon in the ordinary way. The other varieties, *Mrs. A. T. Miller*, *Mrs. L. Thora*, *White Queen* and *Francis Jolliffe* should be allowed to make natural breaks, and natural first-crown buds taken.

PERPETUAL-FLOWERING CARNATIONS (W. D. S.).—As your plants are in such good condition, we should certainly advise you to allow them to flower in the pots they are now growing in, as any disturbance at the present time would cause a severe check. Then, when the flowers are over, the plants may be shortened back, not cut down too hard, and after this operation, when the new growth commences to show, they may be repotted and grown on for another season. For the second year pots from 6 inches to 9 inches in diameter can be employed, the size depending upon the vigour of the specimens. These may be treated in the same way as you successfully followed in the past. If you like, you may plant them out in the border when the season is sufficiently advanced to admit of this being done; but this treatment is not invariably a success, some varieties being better suited to it than others. Taken altogether, we think you will derive greater pleasure from growing them a second year in pots than from planting them outdoors.

DIOSMA DYING (Axioms).—Judging by the specimen sent, your *Diosma* is too far gone to restore to health, whatever treatment you may give it. There is little doubt that it has been practically dying for a long time, and whatever is done now will only hasten the dissolution. In order to keep this *Diosma* in health, it needs a minimum winter temperature of 45° F., rising 10° or so during the day. A free circulation of air, too, is very necessary to its well-being. A compost of good peat and sand pressed down firmly will suit it well. You may, if you like, try to renovate your plant by syringing it with one of the several insecticides, say, prepared paraffin emulsion, or Fir tree oil, but be sure to keep well within the strength recommended by the vendor. *Diosmas* are increased by means of cuttings, put firmly into pots of very sandy peat, placed in the warmest and shadiest part of the greenhouse, and covered with a bell-glass. In order, however, to strike them successfully, good, healthy cuttings are absolutely necessary. After having disposed of the seals, you might, if you are inclined to try, cut it back; but, as above stated, we should not be very hopeful of the result. If cut back, it would be a help to hew it over with the syringe two or three times a day.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Office: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

An Effective Floral Combination.—A few days ago we were much interested to see a large vase filled with Harbinger Wallflower and the scarlet Anemone fulgens. Without seeing it one might well imagine that such a combination would be far from pleasing, but we have seldom seen a better harmony of colours. The vase was seen in electric light, and the effect might not be quite so good under natural conditions.

Trimming Ivy on Walls.—We are often asked which is the best time of the year for cutting back Ivy on walls or fences, and for the benefit of those in doubt we may say that there is no better time than March for carrying out this work. By trimming Ivy at this time of the year, new leaves are quickly formed to take the place of those removed, whereas by trimming Ivy in the autumn, the walls or fences appear bare throughout the winter; and the great charm of Ivy is that it is the best evergreen climber for winter effect.

A Free-Flowering Heath.—Erica lusitanica, perhaps better known in gardens as E. codonodes, is one of the most accommodating Heaths for the garden. It succeeds in almost any soil, providing lime is not too abundant. This Heath attains a height of from 3 feet to 9 feet, and its small, bell-shaped flowers in white and pink are produced very freely indeed. Many gardens are now looking the brighter for this beautiful Heath. It is a native of Southern Europe, and is allied to E. arborea, which it resembles. It may be relied upon for flowering from the present time until midsummer.

A Useful British Saxifrage.—Of the number of alpine plants that flower in March, it is doubtful if any are more generally appreciated than the popular Saxifraga oppositifolia. It is everybody's plant, so easily is it grown in the rock garden. Its bright purple flowers are freely sprinkled over the creeping foliage. It is interesting to note that S. oppositifolia is a native of Britain, occurring wild in the mountains of Scotland. There are many beautiful forms in cultivation, such as maxima, splendidissima, alba, grandiflora and coenocia. This lovely native hybridises with S. biflora and gives S. Kochii.

Blue-Flowering Plant for the Conservatory. There is a handsome member of the Gentian family, known as Eustoma russellianum, that is an excellent subject for the conservatory. The usual flowering period is June and July, when the plants are covered with a profusion of large, cup-shaped, deep blue flowers from 4 inches to 5 inches across. Seed of this plant should be sown in pots or pans at the end of March on the surface of light soil and be placed on a little bottom-heat. Occasionally the plant is met with under the name of Lisianthus russellianus, but it is surprising that it is so little known. A native of Texas and Mexico, it was first introduced into this country in 1804.

The Water Lily Tulip.—There are few more pleasing flowers in the outdoor garden just now than this beautiful Tulip, known to botanists as Tulipa kaufmanniana. On a sunny day, when the flowers are fully expanded and their exquisite beauty fully revealed, they much resemble miniature Water Lilies. The creamy yellow colour, with rich yellow base, looks particularly fresh and spring-like, and it is difficult to understand why this Tulip is not more extensively planted. Possibly it is just a little too expensive and variable in its behaviour, but it is a gem among spring flowers.

How to Prune Buddleia variabilis.—The several varieties of this useful flowering shrub, notably variegata and magnifica, are now to be found in many gardens, but the correct method of pruning does not appear to be generally understood. The best plan is to cut them well back at the present time, removing at least two-thirds of the young wood that was formed last year, and which, in some instances, still carries the old flower-heads. This will induce vigorous growths that will flower well in late summer. After the pruning, a generous mulching with short manure should be given.

Giant-Flowered Asters.—The season for sowing seeds of Asters being at hand, attention may be drawn to a comparatively new and improved type of undoubted merit. In Sutton's Mammoth Aster we have one of the largest types of the Chinese Aster in cultivation. Growing 2½ feet to 3 feet in height, the large, bushy plants produce correspondingly large blooms, resembling the flowers of the Japanese Chrysanthemum. Borne on long, stiff stalks, the flowers are unsurpassed for vase-decoration, and they are also of considerable value for borders. In addition to a wide range of colours from a mixed packet of seeds, six distinct shades of colour are offered separately, namely, dark blue, lavender, old rose, scarlet, shell pink, and white.

A Beautiful Golden Bell.—The superiority of Forsythia intermedia spectabilis over the ordinary intermedia is very marked, for the flowers are brighter coloured, rather larger and produced with greater freedom; therefore it should be selected in preference to the type when one sort only is required. The Forsythias, as a whole, are easily-managed shrubs, for, providing they are planted in moderately good, loamy soil, they give little trouble save for an occasional thinning, which should be done as soon as the flowers fade. They are also easily propagated, for cuttings of short young shoots inserted in sandy soil in a close frame in June root in from two to three weeks' time. An excellent way to use this and other Forsythias is to plant them in masses with a carpet of Chionodoxas or late-flowering Crocuses, for then the golden, bell-shaped flowers of the shrubs expand at the same time as those of the carpet plant below, and a charming effect is produced.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

A Well-Flowered Cyclamen.—As a reader of THE GARDEN I have been interested in recent notes on Cyclamen. Although I have none of venerable age, I enclose a photograph, taken about a month ago, of a two years old plant. When photographed it was carrying fifty expanded flowers, but since that time it has carried as many as seventy-two at one time. It is growing in a 7-inch pot. Plants twelve months old have been

more worthy of a place in the first fifty. Where are the plants to supply bloom during the dull winter months and late autumn when our herbaceous borders are almost bare? Take, for instance, the pretty *Ionopsidium acaule*, *Saxifraga Cymbalaria*, in flower all the autumn and winter except when covered with snow. *Cyclamen Coum* and *C. europaeum* between them supply bloom nearly all the year round, and *C. repandum* is superior to *C. neapolitanum*. Also *Pulmonaria arvensis*, backed up with *Erica carnea*, is lovely during February and March. What have *Cypripedium spectabile* and *C. Calceolus* done? They are no harder to manage than those two beautiful

he tells us that Margaret Madison and Walter P. Wright are practically identical with Seamew? What bold man will back him up when he classes Melba as "practically the same thing as Barbara"? Then he sums up Aurora Spencer as similar to Mrs. W. J. Unwin, but larger. This may be so, but it is not my experience, and, indeed, I think that Mrs. W. J. Unwin, shown as finely as it was at the National Show two years ago, was very nearly, if not quite, the largest flower in the show. The raisers of Sweet Peas are but human, and some of them will find their corns unmercifully trodden upon by Mr. Morse. He has discovered, for example, that Paradise is "precisely the same thing" as Countess Spencer, and that Evelyn Hemus and Mrs. Breadmore are "precisely the same thing." What, I wonder, will he said to this by a celebrated lady raiser. On the whole, I am disposed to think it is rather a good thing for Mr. Morse that a good broad strip of blue ocean separates him from the British raiser. With some of his conclusions, however, I am in eminent agreement, and the unstinted praise which he gives to Stirling Stent for its non-burning qualities is amply justified here.—F. HERBERT CHAPMAN.

Varieties of Saxifraga Boydii.—It is more than a little remarkable that while the merits of the original *S. Boydii* were recognised by a first-class certificate so long ago as March, 1891, the even more beautiful *S. Faldonside* only received recognition on the 4th of the present month, when a charmingly-flowered example was exhibited by Sir Everard Hambro, K.C.V.O., from his wonderful collection of these things at Hayes. The apparent omission may be due to a variety of causes, though chiefly, perhaps, because *S. Faldonside* has never before been presented to the floral committee under its correct name. The same variety has, however, been repeatedly exhibited in collections, though usually as *S. Boydii*, and the knowledge that the latter kind had already received the highest award of a first-class certificate precluded its being again presented. It is now many years ago since I first recognised the superiority of some forms of *S. Boydii* over others, both in the matter of outline, size of flower and colouring, and I concluded it was impossible that all could have been raised from one stock plant originally. This idea so grew upon me—it was patent almost to the ordinary observer of such things—that I presently communicated with Mr. Boyd, the brother of the raiser of the original plant, asking for information. To the direct question as to whether all the *Boydii* then existing were the outgrowth of a solitary individual, I received in effect this most useful informative reply. "The original *Boydii* first appeared as a solitary plant. Subsequently, however, seedlings were raised from it, and these, upon flowering, were considered, some sufficiently near to, and others so identical with, the original that all were distributed under the one name. Later developments however, made it plain that some forms were vastly superior to others." Hence it is that in gardens to-day, and in those more particularly where the entire stock has been raised from a solitary plant, it might prove to be wholly *Boydii* or wholly *Faldonside*. The latter is a perfectly circular flower, the petals broad and overlapping without intervening spaces, the flower remaining slightly saucer-formed almost to the last. The clear yellow colour is enhanced by its sparkling effects. I regard this as the finest jewel in the *Boydii* crown. A good idea of its size and form may be had from the accompanying illustration. By some it is regarded as the best grower.—E. H. JENKINS.

SAXIFRAGA FALDONSIDE, A BEAUTIFUL YELLOW-FLOWERED VARIETY OF THE BOYDII SECTION. (Slightly reduced.)

carrying thirty flowers.—R. T. SAUNDERS, *Park-hewer Gardens, Redruth, Cornwall*. [The photograph sent by our correspondent showed a very good plant, but was, unfortunately, not quite suitable for reproduction.—ED.]

Glory of the Snow (*Chionodoxa sardensis*).—The question is sometimes asked: "Which is the most effective of the Glories of the Snow for planting in grass?" For distant effect I have seen nothing to surpass *Chionodoxa sardensis*, which, though smaller in bloom and more drooping than the others, is self-coloured, or practically so, and gives a more telling appearance at a distance. It is generally free from the white eye of *C. Lucilia*, *C. Tmolus* and some others, but in a few cases *C. sardensis* has a white eye. It is an easily-cultivated species, but, like its sister flowers, appears to prefer deep planting, and if planted too shallow will in time gradually find its way more deeply into the ground. Some people are under the impression that it is called *C. sardensis* because it grows on the spot where stood the City of Sardis; but this is an error, as it was so named by Mr. E. Whittall, its finder, because the ruins of Sardis could be seen from the place where it was found.—S. ARNOTT.

The Fifty Best Alpines.—IN THE GARDEN of March 1, page 115, you have an article by Mr. S. Arnott on "The Fifty Best Alpines for Small Gardens." I consider there are a great many plants

gems, *Haberlea rhodopensis* and *Ramondia*, of which *R. pyrenaica* is the best. There is also the lovely *Cytisus kewensis* var. *heuffelianus*. Why not *Arenaria montana grandiflora*, also *A. balearica* to cover some of the boulders? Why miss *Erinus alpinus* and *Saponaria ocymoides*, *Gentiana*, at least *acaulis*; *Phlox pilosa*, much more free flowering than the setacea group; *Phlox divaricata Laphamii*, *Primulas capitata* and *cashmeriana*, *Draba pyrenaica*, *Achillea umbellata*, *Anemone blanda*, *Aubrietia Fire King*, *Campanula G. F. Wilson*, *Dranthus alpinus* and *D. casius*, both easier to grow than the varied forms of *D. neglectus*; *Hutchinsia alpina*, *Lychnis alpina*, and *Saxifraga bathoniensis* as one of the *Saxifragas*?—G. F. HYLAND, *The Gardens, Ashby St. Ledgers, Rugby*.

Mr. Lester Morse on Sweet Peas.—Americans are a strenuous and go-ahead race, and rarely do things by halves, and I have just received from Mr. Lester Morse a copy of his "Bulletin on Spencer Sweet Peas," in which these qualities are strikingly, even startlingly, exemplified. Mr. Morse has set to work with the very excellent motive of (*inter alia*) cutting down the list of names of the Spencer varieties; but I am disposed to think, and I feel that a good many others will agree with me, that the conclusions he arrives at are much too downright and sweeping. To give an instance or two: What keen expert will agree with Mr. Morse when

Diascia Barberæ as a Perennial.—It was interesting to read in THE GARDEN for March 1, page 102, that others have found *Diascia Barberæ* to be a perennial. Here it has remained outside for several seasons; in fact, it seemed more at home without protection than with it. On the rockery it is a great feature, but I must confess that when grown as an annual it blooms more freely and gives finer flowers. I use it freely in place of *Nemesia*, as its flowering season lasts until late in the autumn. It may be mistaken for the latter at first sight.—M. NICHOLS, *The Gardens, St. Clare, Kemsing, near Sevenoaks, Kent.*

The Valerian.—Your note *re* Valerian on page xxii, of March 1 issue is very interesting. There is no doubt that the Valerian (*Centranthus ruber*), commonly called "Pretty Betsy," is a sea-loving plant. Round here it grows freely on any old wall, and flourishes amazingly. Anyone who has seen the rocks at Barmonth covered with this plant must have been struck by the wonderful blaze of colour. I must say it is a handsome plant and a very telling colour.—J. S. HIGGINS, *Glynllivon Gardens, Camarvon.*

Echium Wildpretii.—I see in THE GARDEN for February 22 a reply to "E. T. D." about an *Echium*. I have a seedling, raised from seed sent me from a plant of my own growing in Allassio, that is everybody's admiration. If it is the kind your correspondent wants, and he will send me his address, I will gladly give it him, or her, if the carriage is paid. My plant is of the clear blue kind, and bears huge spikes or clubs of flowers out there. I am not sure of the right name. It will not stand frost unless well covered, and plants bloom the second year from seed.—(Mrs.) GERTRUDE E. WEST, *Shide Villa, near Newport, Isle of Wight.*

Mysterious Disease of Hyacinths.—I am much interested in Mr. Pearson's article in THE GARDEN for February 22 *re* eelworms. My bulbs have been worried by them lately, especially last spring, and I thought it was my ignorance, as I had not had a greenhouse before. I had a collection of Lilies from Ant. Roozen given to me. For some time they did very well; then the buds began to dry up, and I found the roots were as described in the article referred to, and nearly all my bulbs are spoilt. But they were not content; they killed my *Primulas*, spread into other things—*Sutherlandia* and *Arums*—and ate up all my seeds. I tried everything I could think of to get rid of them, washing the bulbs and repotting in soil that had been dressed with Vaporite. I may say that I had no trouble until one *Lily* had some stable manure in the soil. I noticed every pot that was infested with eelworm had little black flies, with white bands on the body, dead on the soil. This year I have learnt that Oats suffer from a frit fly which produces eelworm. Is it possible that the eggs of the fly could have been in the Oats which came into the stables? I have only used artificial manure this year, and have, I hope, got rid of the eelworms. I had potted Hyacinths which I had last year, and had to burn them all.—B. HALL. [Mr. Pearson, in his article, did not attribute the trouble to eelworms, but to a fungoid disease.—ED.]

FORTHCOMING EVENTS.

March 18.—Royal Horticultural Society's Exhibition at Vincent Square, Westminster. Lecture at 3 p.m. by Mr. R. Lloyd Praeger, F.L.S., on "The Romance of Weeds."

A SIXTEENTH CENTURY VINEYARD AT HADHAM HALL, HERTFORD.

GARDENING has its antiquarian side, and I have lately found in the kitchen garden here something which may be of interest to those who care for the history of gardens. This house is an old one, built *circa* 1572 by Henry Capell, and was, in those days, all that a first-class English country house could be. For reasons which, to save your space, I do not here enter into, the Capell family left it in 1667, when most of it was pulled down, the little that was left becoming a farmhouse.

In 1901 it again became a residence, and, living here since that date, I have endeavoured to find out all that the house and garden were at their best. Partly guided by old pictures and partly by excavations, I have restored, on paper, the foundations, terraces, pavilions and statues which went to make up a garden of that date. But besides all these, I have found one feature of special interest. I had to make a kitchen garden, and for the purpose chose a spot some 335 feet long by 200 feet wide, which offered the protection on the north and east of the old curtilage wall of 1572, which yet remained standing. Certain failures among

for a vineyard. We know that houses of this stamp, at that date, all had vineyards; but I have searched in vain in many gardening books of the period for any suggestion of this way of laying them out.

And, yet, what could be better? Aspect due south, a protecting wall on all sides, those on the south and west kept, as we must think, low, the sun would strike directly into the bays of the six Vine walls, nor would the shade from these affect the wall behind if their height was limited to, say, 5 feet, which would amply suffice for a Vine. The Vines planted in the angles of the bays would not only catch the direct sun, but their branches, spreading right and left along the faces of the bays, would also gain somewhat of reverberated heat. Sheltered in the bays, moreover, the Vines would be well protected from the bite of any east or west wind which might strike into the enclosure. The spaces between the walls would, of course, have been available for ordinary garden purposes, while the reverse side of the walls could have served for Plums and Cherries.

Everything seems to point to the arrangement being intended for a vineyard, though, as I say, I can nowhere find any support for the theory. I should be deeply grateful to any of your readers who could, from a better knowledge of gardens of the sixteenth century, establish it as a fact. Once discovered, it seems strange that the idea has not

PLAN OF A SUPPOSED SIXTEENTH CENTURY VINEYARD AT HADHAM HALL, HERTS.

young Apple trees led me to search at their roots for the reason, where I found foundations of brick walls some 2 feet down. These I followed up, and the plan, which represents what was found, will need but few words of explanation.

The oblong space, now the kitchen garden, runs east and west in its longer direction. Still bounded on the north and east by the old curtilage walls, similar, though no doubt lower, walls enclosed it on the south and west. Inside this enclosure, and running parallel with its longer axis, were six walls, built in zigzags, so as to form bays, of which there were eleven in each wall, making sixty-six in all. These six walls were equidistant throughout their length and 27 feet apart.

I can see but one possible explanation for such an arrangement, namely, that it was meant

survived; for, though we no longer grow Vines in the open, yet such an arrangement would surely be of advantage for our wall fruit. WILLIAM MINET.

Hadham Hall, Little Hadham, Hertfordshire.

[We shall be glad to receive brief comments on the interesting points raised by our correspondent.] —ED.]

A GOOD DRY-WEATHER PLANT.

DURING the scorching days of summer, when the majority of the occupants of the herbaceous border are looking far from happy, it is always of interest and usefulness to note any that appear to revel in the brilliant sunshine and not to mind the drought. One such is the *Gaillardia*, or Blanket Flower, the perennial sort that comes up year after year and gives us its charming flowers so profusely over so long a period.

FIGHTING SPRING FROSTS.

HOW TO PROTECT FRUIT BLOSSOM.

ALTHOUGH the protection of fruit blossom from late spring frosts by means of smudge fires has been extensively carried out for some years in California and other parts of America, there are but few places in this country where the method has been given a thorough and exhaustive trial. It has been contended in many directions that the climatic conditions here do not lend themselves to its successful adoption, and, further, that the protection is too expensive to make it worth while. The latter excuse can at the outset be dismissed, because if the use of smudge fires means the difference between a full crop of fruit and a very poor one, it will certainly pay for doing. The position of the grower is this: for a whole year he has tended his trees, cultivated and manured the soil, and gone to a great deal of expense in bringing the trees to as fruitful a

condition as he knows how. Then one night's frost when the blossoms are open may mean the partial or total loss of this outlay of time and money, a loss that might, as we shall endeavour to show, be to a great extent obviated by the further outlay of a few pounds per acre in fighting the spring frosts.

One of the few places where smudge fires have been extensively and successfully used in this country is The Norrest, near Malvern in Worcestershire. Here Mr. F. Paget Norbury has an extensive fruit farm that is run on up-to-date and strictly commercial lines, and it is by his courtesy that we are able to place before our readers particulars of his efforts in combating spring frosts. Owing to curious climatic conditions that exist at The Norrest Farm, the fields occupied by Apples are not affected by these frosts; but in another direction the Black Currant plantations, of which we have never seen finer, are particularly susceptible to damage, and it is here that the smudge fires have been successfully utilised for the last six years. Believing as he does that if a thing is

worth doing at all it is worth doing well, Mr. Norbury has had wires fixed on insulated poles from the field to his house, where they are connected to an electric alarm bell, the power for which is derived from an ordinary cell battery. On a post in the field a thermometer is fixed about three feet from the ground, as shown in Fig. 1. This thermometer is a maximum and minimum recorder, and at two places a thin platinum wire has been carried through the tube by the manufacturer. As will be seen by the arrow, one of these wires goes through the tube at 30° Fahr., or 2° of frost. To these platinum wires the transmitting wires are attached, and when the mercury reaches the 30° mark it effects the connection and the alarm is given in the bedroom. When this happens, Mr. Norbury promptly telephones to one of his men who lives close to the plantation, and he in turn arouses two more, who proceed with torches and light the smudge fires as quickly as possible. By the time the owner reaches the scene these are well on the way, and are kept burning until after sunrise. Just before sunrise dense smoke is created by adding fresh fuel so that the direct rays of the sun do not strike the flowers.

The fires are made in pots designed by Mr. Norbury, in place of the tunnel-shaped Colorado heaters, which are of flimsy construction. The outer construction of these is well shown in Fig. 2. These smudge pots are filled with straw, specially prepared chips and soft coal, so that a

2.—A "NORBURY" HEATER WITH COVER ON READY FOR USE.

dense smoke and some considerable warmth are created when the fires are lighted. When the fruit blossom is about to open, these heaters are placed in position, and torches and additional fuel placed in readiness for immediate use. During a period of six years Mr. Norbury has found it necessary to light the fires about a dozen times, or an average of two nights each spring, sometimes for only a few hours per night.

It will, no doubt, be argued that such elaborate precautions are expensive and scarcely worth while; but the outlay, taking one year with another is not excessive, and the saving in fruit very considerable. The cost of the Norbury heaters, such as we illustrate, and which are made locally under Mr. Norbury's supervision, is 2s. 6d. each, carriage paid, and forty-eight are required for each acre. Thus the initial outlay on pots is 76 per acre. But those illustrated have been in use six years, and will probably last another six, so that the cost per annum for these is about ten shillings per acre. Naturally, the cost of fuel will be rather a heavy item, but then it is only burned if absolutely necessary.

The thermometer illustrated cost 10s. 6d. and the installation of wires and bell was not a heavy item. From experience gained, Mr. Norbury does not think it necessary to have the thermometer fixed far away from the house, so long as it is in an exposed position and at the proper height from the ground. The temperature at the same altitude within a mile radius is not likely to vary more than 1° or 2° , and this, once local conditions had been fully studied and mastered, could be allowed for. Judging by what we saw at Mr. Norbury's farm and by what he told us, the protection of fruit blossom in this way might be successfully carried out in almost any part of the country. At the Worcestershire County Council's experimental gardens at Droitwich these heaters have been successfully employed by the superintendent, Mr. James Udale, for the protection of Apple blossom, and have proved far more economical and effective than the Colorado heaters.

THE HEATH GARDEN.

(Continued from page 120.)

JUNE is perhaps the month in which we find the smallest number of hardy Heaths in flower, that is, at the full expanse of their beauty, for those that were in full flower during April and May have by no means ceased to provide some colour effect in their respective beds, as the plants retain their flowers and colour, though somewhat faded, for a long time after they have lost their freshness. The later-flowering varieties, too, when only in bud provide a certain amount of colour as a promise of what may be enjoyed in the near future. The varieties, then, that we may expect to find in full flower in the month of June are restricted to two, so far as I can gather from my own observations. These are *Erica australis* and *E. Stuartii*, two plants with very different habits, the former being about three feet high, with flowers of a curious shade of colour, which, for want of a better description, I would call purplish red. *E. Stuartii* is a neat little plant about six inches high, with pretty, rose-coloured flowers, and forms a suitable subject for a comfortable pocket in the rock garden.

From July to September a very large number will be found in flower, and, as little difference can be noted as to their respective times for flowering, I give them in alphabetical order. *E. Lawsonii*, a neat-growing dwarf variety with flowers of a clear red shade, forms a suitable subject for edging. *E. mackayana*, a very pretty red variety growing about nine inches high, also a double-flowered form of the same, found in Connemara, give a pleasing variety among a class of plants represented principally by single flowers. *E. mediterranea multiflora* is the only one in the Mediterranean group that flowers in autumn, all the others flowering in spring. This is a distinct and striking variety, having white flowers with prominent chocolate-coloured anthers. A bed of smaller dimensions might be filled with the last three sorts mentioned, none of these being tall growers. *E. m. multiflora* should occupy the centre, with *E. mackayana* next, either in broad bands or suitable-sized patches, and *E. Lawsonii* near the margin.

The Cross-leaved Heath.—*E. Tetralix* is one of the most distinct of the whole genus, known as the Cross-leaved Heath. The whole plant when not in flower is of a greyish hue. Most of the varieties are about six inches high, a few attaining the height of 9 inches to 12 inches. *E. Tetralix*, pale red, also a white-flowered variety, *alba*, and another, *alba major*, having somewhat larger flowers, are similar in habit. Another white variety called *molle* has slightly shorter and denser flower-spikes, but otherwise similar to the former. *Pallida* resembles the last named except in colour, which is of a very light shade of red. *E. T. praecox* grows somewhat taller than any of the above-named, and has white flowers. All are, however, of neat habit, and suitable alike for the rock or Heath garden. The characteristic peculiarities of the foliage of this section are at all times striking and attractive. A new variety, a hybrid between *E. Tetralix* and *E. ciliaris*, and named *E. T. Watsonii*, is well worthy of being included in the list. The flowers are of a pretty rose pink colour. The plant is a free and vigorous grower, with attractive foliage.

The Cornish Heath (*E. vagans*) is perhaps the most vigorous of all the autumn-flowering Heaths,

and although none of its varieties exceed 18 inches in height, they soon form large masses, and are therefore invaluable for planting in quantity either in the Heath garden proper or for clothing banks where the soil may be too poor for the free growth of shrubs. I have also used this extensively for edgings to walks, and if clipped immediately after it has passed out of flower, it will keep in good order for a number of years before it requires replanting. The type is represented by a plant of compact growth about twelve inches high, bearing flowers of a pale purplish red colour, freely produced on slender, wiry stems that are not easily damaged by rough usage. *Alba* (the white form), *carnea* (pink) and *pallida* (flesh-coloured) differ only in colour from the first named; but a variety called *nana*, possessing a dwarf and neat habit, not exceeding 6 inches in

height. There are numerous varieties of this popular Heath, some of which make excellent subjects for grouping in the grounds either in large masses of one colour or judiciously mixed in beds. The white varieties are in much demand, and must be a source of industry in some districts, judging from the quantities that are to be seen on sale as cut flowers.

White Heather for luck, besides being the badge of a Highland clan, is in much demand for wedding bouquets, and there are few sportsmen who will not sacrifice the chance of a good shot to stoop and pluck a sprig of white Heather when discovered amid a sea of the common purple variety. In the selection of the finest of a long list of varieties of *E. vulgaris*, we would give first place to *E. v. Hammondii*, closely followed by *E. v. Alportii* and *E. v. Searlii*, the former being a very free

3.—ONE OF THE NORBURY HEATHERS IN ACTION. NOTE THE DENSE CLOUD OF SMOKE THAT IS EMITTED.

height, is quite distinct. *E. v. rubra* is the tallest of the group, attaining a height of 18 inches when in full growth, with flowers of a bright red colour.

E. Veitchii is a lovely white hybrid obtained from crossing *E. arborea* and *E. codonodes*. This novelty we have as yet only seen as pot specimens, but from its general appearance it gives promise of being a valuable addition to an already extensive collection.

Common Heather or Ling.—*E. vulgaris* (*Calluna vulgaris*), is too well known to need description, clothing our hills and moors, where during the autumn months it transforms the whole landscape into a rich purple mass, presenting a picture of rare beauty not easily forgotten, especially by those who view it for the first time on a bright autumn day on the slopes of the

growing variety about eighteen inches high, with white flowers produced on fairly long spikes and forming a less compact but more graceful-looking bed than many of the others. *E. v. Alportii* is a very pretty dark red variety growing about one foot high, and where beds of mixed colours are favoured, this makes a fine companion for *E. v. Hammondii*.

E. v. Searlii is conspicuous even when not in flower owing to the mossy appearance of its foliage, which is further enhanced on the appearance of the flowers, which are pure white, of fine form and substance. The whole plant does not exceed 12 inches in height. *E. v. alba* and *E. v. alba minor* partly convey in the names their general description. *Argentea* has beautiful silvery foliage, and *aurea* golden. On a first acquaintance with the last named one might be forgiven for

assuming that the plant was in an unhealthy condition, the appearance from a little distance being a sickly yellow colour in the foliage. *Cuprea* possesses a distinct bronzy foliage, which is more pronounced in winter than in summer.

The variety *fore pleno* should not be omitted, as its double red flowers, having a silvery sheen, are very attractive. The plant is tree-flowering, with a compact habit. A few other varieties of *vulgaris* worthy of mention are *decumbens alba*, *tomentosa alba*, *hypnoides*, *pilosa*, *pygmaea* and *rigida*. These are of slow growth, and are better adapted for the rock garden than the Heath garden.

(To be continued.)

TREES AND SHRUBS.

VERONICA HULKEANA IN IRELAND.

THE owners of gardens in the Midlands and North of England cannot appreciate the value of the New Zealand shrubby *Veronicas* to the same extent as those people who have gardens in the South-West Counties, in South Wales, West of Scotland and in Ireland, for in those places shrubby *Veronicas* are looked upon as a necessity in every garden of any pretensions,

leaves less than an inch long. The flowers are lilac or pale mauve in colour, and are produced in very large terminal panicles, which are peculiarly graceful and pleasing. Under pot cultivation it gives the best results when raised from cuttings at least every second year, but when grown under more generous border conditions it continues to give good results for a number of years. D.

SOME GOOD AND INTERESTING SHRUBS: THE CEANOTHUSES.

UNFORTUNATELY, the *Ceanothuses* are not generally hardy, otherwise there is little doubt that they would find a place in every garden, for no shrubs are more floriferous, while many of them have the advantage of producing blue flowers, a colour which is not common among shrubs. In the milder parts of the British Isles, however, they may be grown to perfection, while in other places the hardier kinds can be grown against walls, though they may fall a prey to cold should a winter of moderate severity be experienced.

That the plants are quite worthy of wall space is evident by the illustration on page 135, which shows a section of a wall in Sir Edward Verner's garden at Corke Abbey, Bray, East Ireland. Sir Edward is a most enthusiastic gardener, and he takes a keen interest in decorative plants. In 1906 he decided to give up a considerable

to be carried out in two different ways, for there are two distinct groups of the genus which blossom at different times. Those which bloom in spring are the more tender, and are usually grown against walls. They require pruning as soon as the flowers are over, the pruning taking the form of cutting back any plants which appear to be outgrowing their positions and spurring the breast wood back to the main branches; but when the same plants are growing as bushes in the open, practically no pruning is necessary. The other group blossoms during the autumn, and it is usual to cut the various kinds back moderately hard during the winter or spring. These kinds are frequently planted in beds in conspicuous positions, while some of them are grown against pillars or walls.

All the cultivated species are natives of North America, the majority being found from Oregon to Southern California, others being met with throughout the Eastern United States, Florida and other parts. The best of the spring-flowering kinds are evergreen in character, whereas those which bloom in the autumn are deciduous or sub-evergreen. In the following notes attention is directed to the most suitable sorts for gardens.

Spring-Flowering Kinds.—*C. cuneatus* is a curious species with rather rigid branches bearing small leaves and whitish flowers. One of the hardier kinds, it may be expected to form a small bush in the open border about London. It is found from Oregon to South California. *C. divaricatus* is an excellent shrub for a wall, while it succeeds as a bush in the South of England. Of vigorous growth, it attains a height of quite 15 feet. The branches are somewhat spiny, and the small, oval leaves are bright and glossy. The blue flowers appear towards the end of May. *C. integerrimus*, like the last-named, is a Californian species, and is suitable for wall culture. Bearing thinner and duller leaves than the majority of the species, it also differs by its large heads of light lilac flowers. *C. Fendleri* has a rather extended distribution, for it occurs in Colorado, New Mexico and Arizona. It is of rather stiff, rigid growth, with somewhat spiny branches, and bears whitish flowers. *C. papillosus* may be readily distinguished by its long, narrow, viscid leaves, which are covered with small oil glands. The blue flowers are produced with great freedom in May. A native of California, it is one of the tenderer kinds. *C. rigidus* is certainly one of the most beautiful of all the species. Of vigorous habit, it grows quite to feet high, and is recognised by its stiff branches, small, deeply-cut leaves and rich deep blue or violet flowers, which commence to open in April. Found in California, it is sometimes grown as a bush in the milder parts of the British Isles, but is more at home when planted against a wall. *C. thyrsoiflorus*, sometimes called the Californian Lilac, is one of the hardiest of the spring-flowering kinds. The popular *C. veitchianus* produces a profusion of showy blue flowers during May.

Late-Flowering Kinds.—Few species are to be found among the late summer and early autumn flowering sorts, but the deficiency is amply met by the many garden hybrids which have been raised. Some of these are decidedly superior to the types for ornamental planting, and flower continuously over a period of three months. The two most important species are *C. americanus* and *C. azureus*. The former is widely distributed through the Eastern United States, where it is known as the New Jersey Tea on account of its leaves sometimes being used as a substitute for Tea. It has whitish flowers and forms a bush

VERONICA HULKEANA IN SIR EDWARD VERNER'S GARDEN AT CORKE ABBEY, BRAY, IRELAND.

while even in cottage gardens some of the stronger-growing kinds are used as hedges for dividing one garden from another. Species such as *V. speciosa* is met with as a bush 4 feet high and 6 feet through, covered in its proper season with upright spikes of lilac, purple, red, or white flowers, according to variety, while other kinds are quite as conspicuous. The accompanying illustration bears testimony to the decorative qualities of *V. hulkeana*, as it is grown in Sir Edward Verner's garden at Corke Abbey, Bray. One of the more delicate species, it is often grown in greenhouses as a pot plant, but in this beautiful Irish garden it succeeds quite well in the open. It is naturally of rather loose habit, with slender branches and broadly oval

area of wall space to *Ceanothuses*, and in May of that year he planted six small plants of *C. thyrsoiflorus* from pots in one position. That they have thriven remarkably well is evident from the photograph, which was taken during the flowering period six years later.

Fortunately, *Ceanothuses* are not very fastidious regarding soil, and providing the climate is right, they succeed quite well in any that is of a loamy nature. They may be increased by cuttings of half-ripe wood, inserted in sandy soil in a close frame indoors during the summer, and it is a good plan to root a few cuttings of each of the more tender kinds each year and keep them under cover for the winter in case of a mishap. Pruning requires

3 feet high. There are several varieties, of which *nanus roseus*, with rose-coloured flowers, and *opacus* are most distinct. *C. azureus*, on the other hand, forms a bush 3 feet to 4 feet high, with large terminal panicles of blue flowers. Two of the most showy garden varieties are *grandiflorus* and *Gloire de Versailles*, both of which are renowned for their fine inflorescences of bright blue flowers. Other good kinds are *Ceres*, rose; *Albert Petit*, rosy lilac; *Brilliant*, purplish; *Cigale*, lilac; *Charles Dérivé*, blue; *Esperanto*, lilac; *Felibre*, mauve; *George Simon*, rosy lilac; *Indigo*, dark blue; *La Condamine*, mauve; *Perle Rose*, rose; and *Rosamonde*, blue.

FLOWER GARDEN.

RELIABLE LILIES FOR THE OUTDOOR GARDEN.

THE Lilies that so greatly adorn our gardens have a wide distribution, especially the great *Martagon* family, which is found in Southern Europe, in Asia, and America. Most of these are entirely reliable. *Lilium Humboldtii*, from far California, and *L. szovitzianum*, from the regions of Northern Persia and Mount Caucasus, are among the grandest of the *Martagonian* representatives. The latter is one of the most majestic Lilies in cultivation. I have had it occasionally in my garden approximating closely to a height of 9 feet, considerably higher, Sir Herbert Maxwell tells me, than it grows at beautiful Monreith, where "all sorts and conditions" of Lilies are assiduously and successfully cultivated.

Of the sub-genus *Cardiocrinum*, whose membership is somewhat limited, the most remarkable illustration is the great Himalayan *L. giganteum*, which may expressively be described as a "reliable" Lily, especially when planted in peaty soil, or in leaf-mould with a slight mulching of manure. Its perpetuation is for the most part accomplished through its offsets, of which the largest usually survives; but it takes at the lowest estimate at least four years to build up its magnificent flowering bulb. Sir Herbert Maxwell, who exhibits great patience and perseverance—splendid moral qualities for an earnest horticulturist—in the culture of this Lily, grows it from seed, which it generates in vast quantities. The foliage of *L. giganteum* is exquisitely heart-shaped, as luminous as that of the Laurel or the Holly, and is highly ornamental. There are several other Indian Lilies of distinctive beauty and characteristics, such as *L. nepalense*, *L. neilgherrense*, *L. Lowii* and *L. wallchianum superbum* (called by Mr. Baker of Kew "*L. sulphureum*"), which are only suitable for conservatory cultivation. *L. candidum* would undoubtedly be one of the most effective and richly-fragrant flowers for garden cultivation, were it not subject to the often fatal influences of an insidious disease. *L. longiflorum*, though extremely beautiful, especially in such fine varieties as *Wilsonii* and *giganteum*, is frequently not enduring, by reason chiefly of its productiveness in the direction of miniature offsets. *L. Brownii*, *L. Kramerii*

and the Japanese *L. rubellum* do not, as a general rule, last very long. On the other hand, I have had *L. Henryi*, *L. auratum platyphyllum*, *L. chalcidonicum* and the exquisitely odorous *L. speciosum* flowering at the same positions for many years.

The longest-lived of all my Lilies, a magnificent *auratum*, was obtained from Messrs. James Carter and Co. nineteen years ago. I have only to add to these fragmentary observations that several of the Oriental Lilies which I have characterised as

Star of the East possesses a stronger constitution than the old types.

For this beautiful and useful flower, as well as for a number of other excellent *Montbretias*, we are indebted to Mr. G. Davison, head-gardener at Westwick, Norwich, a full description of the gardens there, with a portrait of Mr. Davison, being published in our issue dated November 30, 1912. These newer *Montbretias* have been put into commerce by Messrs. R. Wallace and Co. of Colchester, and among those of special merit,

CLANOTHUS THYRSIFLORUS AT CORKE ABBEY, BRAY. THESE ARE FOUR PLANTS, WHICH WERE PLANTED FROM SMALL POTS IN 1906.

unreliable are quite "hardy" in the catalogues, but not elsewhere! DAVID R. WILLIAMSON
Manse of Kirkmaiden, Wigloanshire, Scotland.

COLOURED PLATE.
PLATE 1467.

MONTBRETIA STAR OF THE EAST.

THE year 1912 will long be regarded as a red-letter one in the annals of horticulture, and the *Montbretia* of which we present a coloured plate with this issue will long be regarded as an epoch-making one in the history of hardy flowers. When shown before the floral committee of the Royal Horticultural Society on August 13 of last year, this *Montbretia* was awarded a first-class certificate, a very high honour for a variety of any flower, yet it was an honour that was unanimously agreed upon by the members of the committee, and one that was fully deserved. We have only to compare this new-comer, with flowers nearly four and a-half inches in diameter, with the old *Montbretias* that still do duty in many good gardens to clearly see what a wonderful change has been brought about—a change that has been beneficial in every way, inasmuch as *Montbretia*

though not so large and brilliant as *Star of the East*, mention must be made of *Prometheus*, *King Edmund*, *Lord Nelson*, *Lady Hamilton*, *Hereward* and *Norvic*.

Happily, the cultivation of these useful and beautiful flowers does not call for any great amount of skill. Mr. Davison believes in selecting a rather cool position for them, but not one that is shaded by overhead trees. Then the soil should be well and deeply dug, and a good amount of leaf-soil added to it; and if clay naturally predominates, some coarse grit or other lightening material should be well mixed with the whole, a friable rooting medium that contains a good amount of humus or decaying vegetable matter being the ideal to aim at. Planting is best done in March, covering the corns or bulbous-looking roots with about two inches of soil. Bold groups towards the front of a mixed border, or lawn beds filled with them, are very effective during August, September and October, months when too many of our herbaceous plants are past their best. When the tops get blackened by frost, usually at the end of October, the roots should be lifted, the tops shortened to about six inches, and then stored in a cold frame where actual frost can be kept away. During fine days in winter the stored roots should have as free ventilation as possible.

SCIENCE IN RELATION TO HORTICULTURE.

SHORTENING THE REST PERIOD IN PLANTS.

Forcing by Anæsthetics.—Since the early experiments of Johannsen in 1898 on shortening the period of rest in plants, the practice of forcing bulbous plants or certain flowering shrubs by either the hot-water treatment or by etherisation has become quite familiar to gardeners. Perennial plants have an annual period of rest, and under natural conditions there is a certain normal length of time spent in this state. Johannsen's discovery was that this period could be shortened by subjecting the dormant plant to the influence of an ordinary gaseous anæsthetic, such as chl-roform or ether. The vapour acted as a stimulating agent,

means of raising very early crops of fruits. In one experiment, for example, a batch of 600 plants of the variety *Vicomtesse Héricart de Thury* was divided into two equal lots of 300. One lot was etherised and the other not, and both lots were treated in the way usual in ordinary forcing work. He reports that the treated plants were always superior to the untreated ones, that the etherised lot flowered, as a rule, so much earlier than the others that the fruits began to ripen about fourteen days in advance of the untreated lot. He adds that the method is certainly profitable in the commercial cultivation of the Strawberry.

The dose used was approximately .4oz. of ether vapour per 10 cubic feet of air in the enclosed chamber. The time of exposure was varied. In one experiment the plants were exposed to the influence of the ether for sixty hours, in another for forty-eight hours, and it is stated that it makes

it shortened the period of rest and induced an early opening of the flower-buds. The subject used was *Syringa vulgaris*, or common Lilac. The time of year was the end of November or the beginning of December, and the treatment lasted for two days. In later experiments he used radium itself, and with better results. It acted well with Horse Chestnut, not so well with *Acer platanoides*, and not at all with common Beech; but then the latter, as is well known, does not respond to etherisation. At present this method is far too expensive, commercially speaking, to be of practical utility; but, as has been said, it is interesting, especially as radium emanations exert an entirely different influence upon actively-growing plants than they do in the case of plants during their resting period, as Molisch proposes presently to show.

As an illustration of the possible utility of radio-active substances upon plant growth, reference may be made to Ewart and Nightingall's experiments in Victoria. These experimenters used finely-crushed radio-active minerals, which they mixed with soil, in which they raised crops of Wheat with the object of testing the effect of radio-activity upon growth. The results are hardly conclusive enough to establish any theory, but one notable result came out in the experiment. In cases where the seeds actually touched particles of the radio-active mineral, the greatest increase of yield was obtained.

THE GREENHOUSE.

A RARE AND BEAUTIFUL RHODODENDRON.

(R. SCHLIPPENBACHII.)

THIS species is undoubtedly one of the most beautiful of the Azalea section of the genus, but, except in the warmer parts of the British Isles, it cannot be regarded as hardy.

It may, however, be grown successfully in pots, and will prove quite an acquisition in the conservatory during the early spring months. Although described by Maximowicz in 1863, it does not appear to have been in cultivation in this country for many years afterwards, but a plant shown by Messrs. J. Veitch and Sons was awarded a first-class certificate in March, 1894. *R. Schlippenbachii* forms a deciduous shrub from 3 feet to 5 feet high. The flowers, which are produced in loose umbels, are about three inches across, of a very pleasing pale rose colour, having reddish brown spots near the base. The obovate leaves are borne in whorls at the end of the branches, and are usually produced after the flowers open. This *Rhododendron* is a native of Manchuria and Japan. It is allied to the well-known *R. smense* (*Azalea mollis*).

The *Rhododendron* forming the subject of the illustration on this page is now flowering in the Temperate House at Kew, where three comparatively small plants, some 3 feet or 4 feet in height, each carrying a wealth of blossom, have been the admiration of visitors for some weeks past. This is certainly one of the most lovely *Rhododendrons* of the Azalea section, the delightful flowers, pale rose in colour, being light and graceful in the extreme. For pot culture as a cool greenhouse or conservatory plant, this *Rhododendron* has a great future before it. It is to be regretted that it was not given a less unwieldy name. Another species which somewhat resembles *R. Schlippenbachii* is *R. Mamezu*, a tender Chinese species. W. T.

A RARE AND BEAUTIFUL RHODODENDRON (*R. SCHLIPPENBACHII*) NOW FLOWERING IN THE TEMPERATE HOUSE AT KEW.

producing immediate activity, and on condition that the artificially-awakened life was given a favouring temperature, the plant started growth "right away." In the case of bulbs and flowering shrubs, where the flower-buds are formed the previous season, blooms were obtained many weeks in advance of the untreated plants. It was afterwards found that immersion in hot water for a certain length of time produced the same effect.

Application to Strawberries.—Now Strawberries form their trusses of flowers and lay by a store of ready-made food in their stools during the previous season, so that very soon after the starting of growth in the spring the flowers push out; hence a Strawberry is one of our very earliest fruits. M. C. Bultel, a French grower, has for several years (since 1906, in fact) carried on forcing experiments with Strawberries, using etherisation as a

very little difference which is adopted. The longer time seemed to give only slightly better results. It will, of course, be understood that advantage from etherisation can only be obtained by submitting the plants to the stimulus when they are in a complete state of rest. If the operation is delayed until the stools are ready to start growth, it is obvious that no advantage will be gained by etherisation.

Radium Treatment.—As a matter of interest in connection with this subject, it may be noted that a German experimenter (H. Molisch) has been testing the influence of radio-activity upon the rest period of certain plants. In his first experiments he used not the radium itself, but radium preparations (being much cheaper), and found that exposure to radio-active substances acted as a stimulus exactly in the same way as ether, namely,

GARDENING FOR BEGINNERS.

INCREASING THE CHOICER PRIMROSES.

THERE are various methods by which plants are increased, and, perhaps excepting seeds, propagation by division is the most important. In fact, it is the only way to work up a stock of some plants if they are to be absolutely true to name. Herbaceous subjects are usually propagated by this method, and in one illustration is shown a *Primula* of the pulverulenta and cockburniana type ready for division.

I know that they can be raised from seed, but there occasionally appears a better form than the type, or we may succeed in getting a new hybrid, and out of the batch of seedlings one is far superior to all the others. Such a plant can only be reproduced by division.

Some growers divide *Primulas* after flowering, and this is the usual method for *Polyanthuses* in particular; but I have found that just before growth begins in the spring is a good time for many choice *Primulas*, and then few failures are recorded. For the purpose of more distinctly showing the crowns, a plant with rather advanced growth was selected (see Fig. 1). In the second illustration can be seen the same plant divided into several pieces or single crowns, which are ready to plant in the open ground, and if pot culture is practised, they may be potted up in 3½-inch receptacles as depicted in Fig. 2. Where choice *Primulas* are concerned, placing them in pots is a very good plan, and till they are established a cold frame could be utilised, which would protect them from excessive rains. A rich rooting medium is not necessary, but it is advisable to secure some good loam and leaf-mould, three parts of the former to one part of the latter making a suitable mixture. Only a few potsherds are needed for drainage, and the soil should be pressed fairly firm around the crown.

During the summer months the pots may be plunged in ashes, or similar material, as far as the rims, selecting a position on the north side of a wall or hedge where they will be shaded from the direct rays of the sun. The surroundings can be kept moist by sprinkling the plants overhead with a fine-rosed watering-pot whenever the weather is dry and hot, particularly late in the afternoon, which would cause a dew to be deposited upon the foliage, a condition that promotes healthy and clean growth. As the plants grow, additional crowns will be formed, and further division may be taken in hand till a sufficient stock has been raised.

The object of the present note and illustrations is to show

1.—A PRIMULA WITH STRONG CROWN READY FOR DIVISION.

the amateur how to deal with a choice variety or sport that may by some chance appear among his plants, especially with *Primulas* belonging to what may be termed the japonica section. I may add that the chief points when dividing plants are to see that each portion possesses enough roots, to pot or plant out each piece while in a fresh condition, and to give careful treatment for a few weeks after the operation; while propagation by division is most successfully performed when root action and growth commence. S. T.

2. THE SAME PLANT DIVIDED UP. EACH DIVISION MAY BE EITHER POTTED OR PLANTED SEPARATELY.

HOW TO TREAT BEDDING-OUT CALCEOLARIAS.

CUTTINGS inserted in September or October are often left in the frames until they are lifted for planting out in the flower garden the following spring. This is very bad treatment. The cuttings form radials at the base of the stem of each in the autumn, but they rarely produce roots before the end of January. At the time that the roots commence to grow, the tops do so also, and it is when the latter have made about one and a-half inches of new growth that the points should be pinched out. In about a fortnight's time side shoots will be growing freely, and these form the sturdy, bushy plant. To improve their condition, however, the plants should be lifted and transplanted in a nursery bed at this stage, and there left until the end of April, when, if the beds are vacant, the *Calceolarias* must be planted in their flowering quarters. During their sojourn in the nursery beds only temporary protection against frost and cold east winds need be given. Thousands of these plants die annually soon after they are put out in the flower-beds. I have found that the cause is too late planting in June, too deep planting, and lack of moisture at the roots. If permanently planted in April or early in May, the plants get well established before the summer heat comes, and then few fail. B.

RAISING HONESTY (LUNARIA) FROM SEED.

For growing under trees in woodlands and in open spaces between shrubs, as well as in the grass in any wild part of the garden, *Honesty* (*Lunaria*) is a charming plant. The season of flowering is very early, and when the purple blossoms are faded, the shining creamy white shields are invaluable for room decoration. Seeds may be sown in boxes in cool frames or in the open border. If in the latter, a position facing east or west should be selected, for the reason that the moisture in such borders at this season is more regular than in those facing due south, and evenness of moisture is conducive to free germination of seeds and growth of resultant plants. The latter must be transplanted when large enough in a nursery border, and from this to their flowering quarters before the summer is much advanced; then they will soon get established. The plants look well in herbaceous borders. *Lunaria annua*, light purple, is annual or biennial; *L. a. albiflora*, a lovely white, and *L. rediviva*, purple, is a perennial variety. AVON.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Narcissi planted under trees and on banks in the flower garden have in many instances bloomed very early this season, and for the sake of tidiness the flower-stalks should be picked off as soon as the flowers become withered. There is often a decided inclination to cut the grass when these subjects have bloomed, but this should not be done for some time, at least not till the foliage shows signs of turning yellow.

Planting Out Forced Bulbs.—In many instances these are relegated to the rubbish-heap, but there are often very suitable places for planting these in the wilder parts of the flower garden or by the sides of the paths in the copse, which in many instances adjoins the garden proper. By planting at this season one can see that they are not placed on the top of other clumps, which often happens if left till all the foliage has died down in the autumn, and the bulbs are not left about all the summer in the pots.

Hyacinths are now throwing up well in the beds, and in sheltered positions they may thus early require support. It is best to do the staking at once, as one night's wind and wet may break off a good many of the flowers and so spoil the effect.

The Rose Garden.

Pruning.—The exceptionally mild winter has kept many of our Roses in an evergreen state, and though tall early for the general pruning, a start might well be made with the later-flowering Hybrid Perpetuals. Generally speaking, good hard pruning is best for most varieties, especially where quality is desired in preference to quantity.

Pegging Down.—There are, however, many strong-growing varieties, such as J. B. Clark, Hugh Dickson, Frau Karl Druschki and Mme. Jules Graveriaux (this latter a Tea), which make a very fine show when pegged down to within about a foot from the ground, choosing three or four, or even more, of the strongest and best-ripened shoots for the purpose. This system requires a good deal of room; but vigorous varieties, such as those named, are usually planted at a good distance apart, and the quantity of bloom thus obtained is far in excess of that from plants pruned in the ordinary way.

Pricking Over the Beds.—Needless to add, after pruning, all the beds or borders should be lightly forked over, thus burying any manure that may have been given as a top-dressing earlier in the year, at the same time firming any plants with the heel that may have been blown about by the wind during the winter.

Plants Under Glass.

Imantophyllums are among the hardest and easiest-grown greenhouse plants, and may be had in bloom over quite a long season. Plants that have been forwarded in a warm house may now have gone out of flower, and if it is desired to increase the stock, these may be divided to single crowns and potted into 4½-inch and 6-inch pots, in which they will prove quite useful for decorative purposes. Plants throwing up their flower-spikes may be liberally fed with liquid manure.

Hanging Baskets.—These are often a decided feature in the houses or conservatory where there is plenty of head room, and may be made up of a variety of subjects, either of the stove or greenhouse. Among Ferns, *Nephrolepis* is probably the most popular for the purpose, while *Acalypha hispida* and *Musaica* make nice showy baskets in very quick time, and are made more effective by covering the baskets with *Panicum*; while *Crotons*, *Dracena godseffiana*, *Begonias* (both foliage and flowering), *Arhemesus*, *Fuchsias* and lily-leaved *Pelargoniums* are all useful subjects. When once established, baskets will take an almost unlimited supply of water, and for this reason should not be placed where the drip from them is likely to injure other plants.

The Kitchen Garden.

Sweet Corn.—For an early crop a small sowing should now be made under glass, potting the young plants off into 3-inch pots as soon as large enough to handle. A great deal of heat is not necessary

for them, but just enough to keep up a steady growth.

Celery.—For the main crop this should now be sown in boxes, or thinly in a frame on a hot-bed. To obtain the best results a steady growth from the outset should be encouraged, rather than subjecting the seedlings to a great heat at the start.

Beetroot.—A small sowing of Turnip-rooted Beet should be made in light soil not too rich in manure, or the roots will quickly grow beyond a useful size.

Hoing.—The hoe should be kept going whenever the opportunity offers among the growing crops. This will help them considerably by allowing the sun to warm the soil.

Cabbages will benefit greatly also by having a slight sprinkling of nitrate of soda before the above operation is done; but it must be kept off the foliage, or it may spoil its appearance unless it is immediately washed off, and certainly at this season a watering is quite unnecessary.

Fruits Under Glass.

Figs that are commencing to grow nicely should have the temperature increased somewhat at night, and as the shoots lengthen and the fruits commence to swell, they should be pinched at the fifth or sixth leaf. Thinning the fruits also may be necessary in some instances, but only where a very heavy crop is being carried. Shallow borders should be given frequent waterings, a drought at the time the fruits are swelling being disastrous, and possibly resulting in the total loss of the early crop.

Melons.—Every encouragement should be given to the early batch of Melons, and if grown on the cordon system, the points may be pinched out after the plants have made sufficient side growths to ensure a crop. If planted fairly close, it is best to let the first pair of fruits that are set grow away, rather than wait till a greater quantity are set at one time, as it may mean a difference of a week or two in the time of ripening, and the earliest fruits are always the most appreciated.

THOMAS STEVENSON

(Head-gardener to E. Moratta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Removing Protecting Materials.—If the weather is at all reasonable, protecting materials may now be removed from Tritomas, Gunneras and other plants of doubtful hardiness.

Hollyhocks.—These stately, old-fashioned flowers may now with safety be planted in their flowering quarters. The ground, having been previously manured and trenched, should now be forked over, pits taken out, and partly filled with some light, rich compost to give the plants a favourable start. If had in separate colours, Hollyhocks look well in clumps of three or four towards the back of a mixed border.

Anehusa italica.—The Dropmore variety of this Alkanet is a grand subject for mixed beds and borders. Plants in the reserve garden should now be removed to their permanent quarters in soil that has been deeply dug and well enriched.

Montbretias.—New purchases and tubers which have had protection during winter should now be planted out. Montbretias delight in a rich, friable soil with cool, moist conditions. Among the better varieties are *Prometheus*, *Germania*, *George Davison*, *King Edmund*, *Vulcan* and *Hereward*.

Half-Hardy Annuals.—The remainder of these should now be sown in gentle heat, keeping them close and shaded till germination takes place. East Lothian Stocks are apt to damp off if left too long in the seed-box. As soon, therefore, as the first pair of rough leaves are well formed, the plants should be pricked off into deep boxes of light, rich soil, or into a frame that has had a little fermenting material placed in it. Beware of drip, as the plants are very liable to damp off.

The Rose Garden.

Pruning.—In all but very cold localities the work of pruning bush Roses may now be commenced. I have heard of considerable damage among Roses during the past winter, but here

they have come through practically scathless. In pruning, the following is the order in which they should be taken, allowing about a fortnight from start to finish, viz., Hybrid Perpetuals, Hybrid Teas and Teas. Only general principles can be laid down here. In tackling any one bush, first cut away all dead, diseased, extra weak and soft, badly-ripened shoots, after which, where still too crowded, thin out more shoots, retaining those of medium vigour if well ripened. Vigorous growers should have the shoots shortened to ten or twelve buds, while weak varieties should be pruned in fairly hard. If intended for exhibition, Roses should be pruned harder relatively than when only wanted for decorative purposes.

The Shrubbery.

Planting Evergreens.—The planting of evergreen shrubs may be carried out from this time till the beginning of April. The planting of Hollies is best carried out in August, and Rhododendrons should, for choice, be planted in October. The latter, if handled carefully and well watered, may, however, be planted now. When planting, the claims of such subjects as the following should not be overlooked, viz., *Andromeda floribunda*, *Kalmia latifolia*, *Osmanthus illicifolius*, *Skimmia japonica* and *S. laurifolia*.

The Water-Side Garden.

Planting.—Those who are fortunate in having a lake or stream within the grounds, if they have not already done so, would be well advised to invest a little money and labour on water-side gardening, from which great pleasure may be derived. Given suitable soil, most of the subjects will take care of themselves after planting. I can only indicate a few in alphabetical order: *Arundo conspicua*, *Astilbes* in variety, *Carex Fraseri*, *Iris Pseudacorus* and its variegated form, Japanese *Iris* in variety, *Mimulus cardinalis* and the common Monkey-flower, *Myosotis palustris semperflorens*, *Podophyllum peltatum*, *Primulas* in variety, especially pulverulenta, rosea and varieties of japonica, *Rodgersia podophylla* and *Rumex viridis rubrumervum*.

Plants Under Glass.

Caladiums.—Those started in small pots should now be ready for a shift, using pots according to the vigour and size of the plant. A mixture of loam, peat and leaf-mould, with a little dry cow-manure, pounded charcoal and sand, will be found suitable. Start the later batch in small pots.

Mignonette.—The autumn-sown batch will now be showing their flower-spikes. Give abundance of water, adding a little stimulant till the flowers are nearly expanded.

Pelargoniums.—The Royal varieties should be pinched before they become leggy. Zonals which were cut back a few weeks ago and have started into growth should have their balls of soil reduced and be repotted. Seven-inch pots will be generally suitable. Three parts loam to one part dry cow-manure, adding a little bone-meal and sand, will suit them.

Sowing.—A sowing of *Zea japonica* variety (improved variety), *Kochia trichophylla* and *Amaranthus salicifolius* may now be made for autumn decoration.

The Kitchen Garden.

Onions.—Those that were sown in heat in January will now be ready for pricking off. Use deep boxes, place a layer of spent Mushroom manure in the bottom and fill with rich soil. Prick out about two inches apart.

Celery.—The main batch may now be sown in light, rich soil in some warmth. We stick to Wright's Grove White and Pink, the latter for the late winter and spring supply.

Peas.—Another sowing should now be made. There is great choice. Alderman is hard to beat as a tall variety; but if a medium-height variety of good quality and a good cropper is wanted, Senator will fulfil all expectations. Where sparrows are troublesome (and where are they not?), Pea guards must be placed on the early sowings.

Turnips.—Although still risky, a sowing of one of the Milan varieties should now be tried on a south border.

Liming.—Lime is of great value, especially on clayey and peaty soils. Now is the time to apply light dressings of it in the ground form; cover it lightly with a hoe or rake.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mans, Midlothian.

DAFFODIL NOTES.

DAFFODILS AT VINCENT SQUARE.

MARCH 4 AND 5.

THIS show is called in the Royal Horticultural Society's list of fixtures the "Forced Bulb" Show. The intention of those who first suggested the fixture was primarily to provide an opportunity for showing the general public which varieties of Daffodils were the best for pot cultivation; hence the notes that follow are going to be written to carry out this idea. I do not think half enough people know the charm of growing a small and select collection under glass. I could enlarge on this to any extent, but I must content myself with the suggestion of a dozen good varieties that might be grown singly in 5-inch or 6-inch pots. Take Weardale Perfection, King Alfred, Duke of Bedford, Stromboli, Southern Star, Lucifer, Homespun, Castle, Diana, Seagull, Firebrand and a nice Giant Leedsii like White Countess. These would make a charming and varied little lot, which might be still further improved by the addition of a Poet like Homer and a Poetaz like Orient or Jaune à Merveille.

I have, however, in my mind rather what one may call good pot plants; plants, that is to say, which should be grown in the ordinary way in pots, and which seem to me to especially lend themselves to the treatment. One of the surprises of the show was the absence of Topaz. To me it is so pleasing that it seems strange that no one brought it. It has a long, narrow, almost all-red cup, while its creamy white perianth segments are narrow and stiff and throw themselves slightly back. It is a good doer and by no means an expensive variety, being priced at about two shillings and sixpence per dozen. A pot of it was just coming into flower when I left home. Of those that were there, in the front rank I would place Weardale Perfection and Duke of Bedford. These were very well shown by Messrs. Walter T. Ware, Limited. The first named is so immensely improved by being grown under glass that it might easily be mistaken for another variety did one not know its little ways. I heard Mr. Engleheart eloquent on the subject at the Horticultural Club one evening. When he "lets himself go," you may take it from me that there is "a good deal in it." Thora, the beautiful buff-cupped Giant Leedsii, was also on this stand. I have never seen it better done. It is an extremely well-balanced flower, the perianth, which is slightly twisted, going so nicely with the short trumpet or large cup. It is a real gem.

Messrs. Barr and Sons had the three sisters Sunrise, Sunbeam and Mohican in their interesting collection. I mention them because the last named is said to be very good indeed in pots when not forced. As, however, everything came from their new garden near Penzance, the actual flowers staged were no criterion of their pot capabilities. I am rather sorry that it was so, as all the other groups had obviously been grown under glass, and it is quite likely many of the public did not realise this difference. But of these and also of some of the novelties staged elsewhere more will be given next week.

Messrs. J. R. Pearson and Sons (erroneously referred to in last week's report as Mr. J. Duncan Pearson) had their blooms rather on the small side, but they were fresh and clean. Scarletta, grown in their Nottinghamshire home, looked very pretty. The deep cream perianth

blends so well with the red cup. It is a great thing to know that a variety can be grown outside any favoured climatic zone and bear forcing. Firebrand is one of these, and so is Lucifer. Both were on this stand. I was glad to see two nice bunches of Florence Pearson, their grand white trumpet. At present it is expensive, but I have an idea that in the more or less distant future it will be Florence Pearson and not Mme. de Graaff that will be the great white trumpet of commerce.

Messrs. Cartwright and Goodwin had some splendid Incognita and Castile. I have not grown the first named in pots myself, but I have the latter. It is a real good thing for the purpose, and never seems to tail. Lady Margaret Boscawen, Fairy (yellow trumpet) and Olympia also deserve mention. Seagull was also there, but it was not at its best. It is a variety that I think very highly of. With the exception of last year it has never failed to give an excellent account of itself when grown under glass. It was then small, just as the

He had a beautiful group, full of choice new things, such as Roxana, Dazzler, Alpine Snow, Suidbad, Wendy and White Countess. Of these anon I only mention to-day George Herbert, a pretty little round Poet which promises well, as the blooms staged were grown at Bletchley in 1911-12. (Poets that do well anywhere are very much wanted. I hope there is nothing rotten in the state of Denmark, but I have my fears. It is not all gold that glitters, and it is not every Poet that is a garden laureate.) Apricot is another variety that is distinctly flattered by the protection of glass, as it is then that the pink flush is most marked on its pale apricot trumpet; and Orient, the tall, red-edged Poetaz, one of the very best of its class, and of which my friend Mr. H. G. Hawker remarked, as we stood together before it, "Of the whites Orient, and of the yellows Jaune à Merveille; I don't want to grow any others."

All the foregoing varieties that I have mentioned in detail are good in pots. In almost every case I have grown them myself, so I not only

MAZUS RUGOSUS, A RARE DWARF-GROWING ALPINE WITH DEEP MAUVE OR ROSE-VIOLET COLOURED FLOWERS.

vase here was. I hope it is not going to belie its promise of being one of our most valuable pot plants. It comes so easily and it is so very floriferous.

I greatly admired a bowl of Lulworth exhibited by Messrs. R. H. Bath, Limited. I am not, as a rule, in love with growing in fibre. This Lulworth was the exception that proves the rule. It was "jolly good." What a fine companion this would be to W. P. Milner, which, like Weardale Perfection, is only seen at its best when grown under glass!

Among the flowers from Robert Sydenham, Limited, were the two trumpets Olympia and Cornelia. The first is a big, rough flower, which I find appeals to many people on this very account. The second is its antithesis, smooth and refined. Both have their admirers, and so both are mentioned here, for the Daffodil family can indeed be "all things to all men."

The highest award of the day—a silver-gilt Banksian medal—tell to Mr. C. Bourne of Bletchley.

see, but I know, which is far better. *Experientia docet.*

JOSEPH JACOB.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Syringa (Lilac) Hugo Koster.—This novelty promises well as an early forcing variety. The handsome pyramids of flowers as shown were coloured a pale lilac, the individual flowers being of large size and well formed. In its natural flowering season in the open we imagine it would prove one of the most attractive and distinct. From Messrs. Koster and Sons, Boskoop, Holland.

Mazus rugosus.—A neat and pretty early-flowering alpine from the Himalaya and a perfect carpeter of the soil. The violet or deep mauve coloured flowers are produced singly on inch-high peduncles, and are characterised by a three-lobed lip, on which are two sulphur yellow, longitudinal lines marked with violet spots. The flowers are

about an inch or so long, and appear above the carpet of lustrous green, crenated leafage. See illustration, page 139. Exhibited by the Wargrave Plant Farm, The Arcade, Liverpool Street, E.C., and Twyford, Berks.

Saxifraga Faldonside.—This is one of the yellow *Boydii* race, and perhaps the gem of the little set to which it belongs. The perfectly circular flowers are nearly the size of a shilling and of a clear lemon yellow colour. The plant has the reputation of being a better doer than *Boydii*, but in any case it should be given a sheltered place in the rock garden or be grown in the alpine-house. From Sir Everard Hambro, K.C.V.O., Hayes Place, Hayes, Kent (gardener, Mr. J. Grandheld). See illustration, page 139.

NEW ORCHIDS.

What was undoubtedly one of the finest hybrid *Odontoglossums* yet raised was shown by Messrs. J. and A. McBean of Cooksbridge. It is a variety of *O. eximium* named Alpha. The flowers, of remarkably good form, are densely blotched with chestnut red. First-class certificate.

Awards of merit were granted to the following: *Cattleya Trianae* Colossal, from Lieutenant-Colonel Sir George Holford, K.C.V.O., Westonbirt; *Odontioda Mossiae* and *Miltonoda Harwoodii* Moss's variety, both from J. S. Moss, Esq., Bishop's Waltham; *Dendrobium bigibbum* Lady Colman, shown by Sir Jeremiah Colman, Bart., Reigate; *Oncidioda Cooksoniae* Ralli's variety, from Pantia Ralli, Esq., Ashted Park; and *Lælio-Cattleya Smilax* Prince of Orange, from Messrs. J. and A. McBean.

The foregoing awards were made at the fortnightly exhibition of the Royal Horticultural Society held on March 4.

NURSERY NOTES.

ANNUALS AT READING.

FOR some years now we have visited the seed trial grounds of Messrs. Sutton and Sons, Reading, for the purpose of inspecting the vast array of annuals there grown, and, incidentally, to note the differences of the varying stocks of this or that—it may be the Sweet Pea, Aster, Stock, Snapdragon, Carnation, *Eschscholtzia*, or what you will—their trueness to colour, compactness of habit, freedom or superior flowering attributes, or any other matter which for weeks on end each year engages the attention of the firm, and, while making for progress—one of the great aims of it all—stamps this, as indeed all other undertakings of Messrs. Sutton, with the hallmark of excellence.

Novelties may, as indeed they do, exist at the present time in these famed trial grounds; but until they have become of good report, till they have satisfied the exacting requirements of the firm as to their reliability, they are not for the public, nor is the journalist permitted to say anything concerning them. It is all a question of principle, and that phase of it in particular which never starts before being ready, and never adds one jot or tittle that will not sustain the eminence and reputation of this world-renowned firm to the sumptuous volume the firm prepares and distributes.

Perhaps one of the most valuable of the many lessons to be gathered from an inspection of these trials is due to the fact that the majority of the seeds are sown in the open ground; hence we see

such as *Schizanthus*, *Dimorphotheca*, *Kochia* and others affording object-lessons of considerable importance. In such instances the sturdy-habited, well-dressed plants are goodly to look upon, and, hardly grown from the start, have a greater power to endure than others of the same kind raised in warmth. This much was particularly well evidenced in the case of the first two groups named, and the gardener should lay the fact to heart. It is of the greater value, too, in the case of tap-rooted or sparsely-rooting subjects, since upon the retaining of every root-fibre formed is the fullest measure of success assured. There are others, however, such as the Snapdragons (*Antirrhinums*), which, while admitting of being sown in the open in July and transplanted to their flowering quarters in the September following, are raised here for convenience in slight warmth in February and transferred to the open ground in early May, a steady growth being maintained meanwhile. The plants so raised last year were, at the time of our visit in early August, a field of colour difficult to imagine, impossible to describe. Some there are among amateurs to-day who, while delighting in these flowers, just miss the fullest measure of success noted by over-thick seed-sowing and by starving the seedlings before transplanting them. These are the checks from which they seldom recover. Now these *Antirrhinums* are such an important race—hardy, free-flowering and effective when massed—that they are worthy of much consideration. That they exist in the "Tom Thumb" forms at 6 inches high, in the "Intermediates" at thrice that height, and in the "Talls" at a yard or more high, many will know quite well. Yet how few gardeners appear to have dreamed of combining all three of these in a single border, securing thereby one great glorious gallery of flowers, of which, so far as we remember, no other plant is capable. Yet the idea is not only possible; it is easy. The material exists in abundance and in colours to suit all tastes. It is merely awaiting a due appreciation of the fact. One might, indeed, garden with these Snapdragons in a dozen varieties—white, pink, yellow, rose, carmine, crimson and others—in each or all of the sections, and thereby create a display worth a day's journey to see. That the colours are repeated in each section, too, renders the plants suitable for small and large gardens alike, and a border 100 feet or 200 feet long would be a sight to see. In the boldest borders the two taller sections might predominate, while in borders of lesser size the dwarfs and intermediates might prevail. Thus arranged, the plants would become a feature, and Snapdragon-time in the garden would be something to aim at and remember. One of those we saw at Reading was Fire King, a most brilliant flower; while Bright Pink, Coral Red, which has a white throat; Deep Crimson, which is a velvety maroon; Carmine Pink, Rich Apricot, Orange King, Delicate Pink, and Pale Apricot, of orange, pink and white, are others good and distinct. The whole of these come practically true to their kind; hence good effect can be relied upon. We have dwelt upon the Snapdragon at some length because of its hardiness, free-flowering and general popularity.

Quite one of the best object-lessons noted concerned the Tom Thumb *Nasturtium*, which gardeners know objects to richly-manured soils. "Objects" is perhaps the wrong word, for the plant just delights in them, the excessive luxuriance of the leaves quite overwhelming the flowers. The great central avenue in the trial grounds was bordered with these and other showy flowers, and in several

instances the corners of the borders had been temporarily utilised as a "tip" for manure; the result a splendid crop of leaves and few flowers. Beyond the limit of the "tip," The King, the chief variety at the spot, made a most brilliant display, and in soil that had remained unmanured for twenty-five years. In such circumstances the moral is as plain as the double-barrelled "tip," if flowers and not a leafy luxuriance is the aim.

We have referred to the great central avenue here, which was more in the nature of display work than a trial, and for the benefit of our readers who delight in spectacular effects we give in conclusion some of the plants employed. Near the railway, *Nasturtium* The King blazed forth alone; while in other parts the white *Alyssum* constituted its foreground, with *Godetias* Duchess of Albany (white), Crimson King and Marchioness of Salisbury (rosy crimson and white), and Evening Star *Chrysanthemum* at the back. Other sections of this effectively-massed border were made up of *Chrysanthemum* *segetum* varieties, such as Northern Star, Morning Star, Eastern Star and the equally remarkable range of colours found in the tricoloured forms of *C. carinatum*. *Clarkias*, hybrid *Lupines* and the annual *Larkspurs* were alike showy and choice, though to the Orange King *Marigold* must be assigned the pride of place, a plant undeterred by heat or cold or wet, and whose brilliant and free-flowering attributes are alike incomparable.

ANSWERS

TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—*The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

SUMMER BEDDING PLANTS (*An Admirer*).—If the *Geraniums* become so spindly and drawn by reason of the near proximity of the trees, we fear other plants will meet the same fate, and nothing short of repeated experiments with diverse classes of plants will be of much service. For this season at least we should be inclined to try hybrid *Pentstemons* in variety, crimson and scarlet shades, more particularly orange or white flowered tuberous-rooted *Begonias* in their immediate front, and a broad band of *Godetias* as a margin. You might relieve the brilliancy of the first named by interspersing the plants with others of the white *Tobacco*, which is also a free and continuous bloomer. Unfortunately, you do not give either the width or length of the border, hence we cannot assist you other than from the general standpoint.

SNOWDROPS AND DAFFODILS (*J. G.*).—We imagine from the behaviour of the plants that the position is too dry for both, and the first named, after two years, should now be flourishing. These are not strictly moisture-loving plants, though a considerable depth of loamy soil is very much to their liking. If in addition to the sandy and gravelly soil the position is one of exposure, that would account for the small size of the flowers, and unless you can modify these conditions, we fear there will be little improvement. *Narcissus* *princeps* is one of the best to naturalise, but prefers moist woodland clay soil. We know instances of such that have remained undisturbed for twenty years or more, the plants having become giant tufts in the meantime. It is quite possible that deep digging, manuring of the soil and replanting in August may improve matters. At the moment all you can do is to flood the ground, if possible, and apply a little nitrate of soda at the same time.

EDITORIAL NOTICES.

Every description of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Date of Midland Daffodil Show Altered.—The date of the above show has been altered from April 23 and 24 to April 22 and 23.

Increasing Lavender.—Quite large pieces of this plant will root freely if slipped from the old plants and firmly embedded in the soil. With very little attention the majority will soon develop into quite large bushes; and no time should now be lost in getting them planted.

The Purple Pershore Egg Plum.—This Plum is being planted extensively by growers in the Evesham Valley, where it is likely to eventually supersede the Yellow Egg Plum. The purple variety originated as a sport from the yellow type, and has the same characteristics, being worthless for dessert, but excellent for preserving.

Renovating Gravel Walks.—Now that most of the heavy work of the garden is completed, the gravel walks should have some attention. Where the surface is moderately good, it may be turned over with a fork to about a depth of two inches, levelled and rolled well down. A path treated in this way will look fresh and bright for some time. In many cases it is also necessary to add some new surfacing material, but it must be of good binding quality.

The Glory of the Snow.—Few early spring-flowering bulbs equal the delightful effects obtained by liberal plantings of *Chionodoxa*. Of the several ways in which they may be planted in our gardens, one of the best is as a groundwork for beds of deciduous shrubs. In such positions the bulbs flower before the appearance of the foliage on the shrubs, and the soil is seldom disturbed except just on the surface. The bulbs increase rapidly by means of offsets and self-sown seeds.

Propagating Thyme.—If a packet of good seed is procured and sown at once in pans and stood in mild warmth, a good supply of young plants may be quickly raised, and with a little attention will soon develop into a nice useful size for planting in well-prepared beds at the end of April. This is the best plan when there is a scarcity of older plants. If there are enough of the latter, pull off young pieces and plant them in small tufts, burying the older wood rather deeply. Make the soil firm, and water a few times if needed till well rooted.

Mounds of Crocuses.—The planting of these delightful spring-flowering bulbs in grass is being gradually extended, more particularly in public parks and gardens. For some years now Crocus-time at Kew has drawn large crowds of visitors on fine Sunday afternoons in late February and March. The most effective plantings at Kew are on mounds or sloping ground, generally in the vicinity of deciduous trees where the grass is not too thick. With the green grass as a groundwork,

the effect is much more pleasing than the soil of beds and borders. If, however, the position is too open, the grass generally grows too thickly, and in time the Crocus bulbs deteriorate and dwindle away.

Modern Cornflowers.—Unlike most other flowers, the humble Cornflower of our fields has been spoiled by florists in the attempt to secure colours other than the deep, brilliant blue which is the main charm of the wild plant. The so-called rose and white-flowered varieties are washed-out caricatures of one of the most beautiful of our native flowers, and are not worthy of a place in our gardens. Even some of the blue-flowered varieties offered for sale are not so good in colour as those we were wont to see growing in the cornfields.

The Canary Creeper.—Seeds of this pretty climbing plant, also known under the name of *Tropaeolum canariense*, should now be sown in pots of light soil under glass, or placed in the open ground during the month of April. There are a number of situations, both in small and large gardens, where this showy subject could be utilised with telling effect. An old stump of a tree may require covering, arches need furnishing, and a few clumps in the flower border would be an additional charm if allowed to ramble over Pea sticks. Amateurs who take an interest in window-boxes will find the Canary Creeper very suitable for trailing over the sides.

A Shrub to Grow Under Shade of Trees.—*Pachysandra terminalis*, a low-growing shrubby plant, is one of the most useful subjects to thrive satisfactorily under trees, and therefore one well worth including in collections. It is a native of China and Japan, evergreen and of dwarf habit, and has been known for some time, but seeds were recently sent to England among those collected by Mr. E. H. Wilson. From the Continent comes a very attractive variegated form, which appears to be quite as robust as the former. Both have white flowers, freely borne in March and April, and should prove useful shrubs for inclusion on rockeries because of their low and not too rapid spreading habit.

The Protection of Eremurus.—These handsome plants are gradually, but surely, finding favour; but their liability to suffer from early spring frosts is a great drawback. This, however, can be partly, if not wholly, remedied. At the present season they are about to send up their spikes, but unless some means of protection is given, they may be irretrievably ruined by frost. A few pieces of Bracken can be employed, or an Archangel mat supported by a stake or two will prove effective, while various other methods will occur to the thoughtful cultivator. A mistake is often made when selecting a position for these noble plants. The best aspect is north-west, or wherever the morning sun cannot shine full on them.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Lilium sulphureum as an Outdoor Plant.—

As I have twice lately read articles in THE GARDEN on Lilies, where it is stated that *Lilium sulphureum* (or *wallichianum superbum*) cannot be considered a garden flower as it requires heat, I am writing to tell you that I grow it quite successfully in my small garden here. Planted in a pocket of sand in the border, it produces beautiful

as I have done regularly these fourteen years past, usually about Christmas. May I be allowed to add as some slight proof that it has had no untoward effect, that I have been quite reasonably successful in the exhibition tent.—N. W. M.

A Useful Greenhouse Plant.—*Rehmannia angulata* is a most useful subject for the decorating of any cool glass structure. I recently saw a batch of the plants in the greenhouse in Waterlow Park, Highgate, which is thrown open to the public. They looked healthy, with spikes about half grown. At their best they attain a height of 3 feet to 4½ feet, and have a long season of flowering. The

Eustoma russellianum.—Time was when this beautiful Gentian-wort, referred to in "Notes of the Week" of the issue for March 15, was met with far more frequently than it is at the present day. Grand specimens were at times exhibited, and, being particular in its requirements, it was regarded as a good test of the cultivator's skill and attention. It says a great deal for the old-time gardener that with the more primitive structures and system of heating he used to grow fine examples of many plants that may now be sought for almost in vain. This *Eustoma*, which in the olden days was known as *Lisianthus russellianus*, is a native of Texas. The specific name is in honour of one of the earlier Dukes of Bedford. By sowing the seed early in the year and growing the plants on freely it may be flowered the same year, but the most satisfactory way to obtain fine specimens is to treat it as a biennial. If sown in spring and the young plants are sturdily grown, they will by the winter be established in pots from 4 inches to 5 inches in diameter. About the end of February they may be put into their flowering pots. In an 8-inch pot a large specimen can be grown. A mixture of loam, leaf-mould and sand will suit this *Eustoma* well. Like many of the Gentian family, the roots are delicate, so that they must be carefully handled and excesses of drought or moisture avoided.—H. P.

Reliable Lilies for the Outdoor Garden.—

The list of reliable Lilies from your correspondent the Rev. David R. Williamson, page 135, issue March 15, is decidedly limited, and additions might well be made thereto. For instance, what more dependable Lily have we than the old orange *Lilium croceum*? It will thrive in the ordinary border without any preparation, and increase quickly by means of its numerous offsets. That it is reliable enough is proved by the fine examples met with at times in cottage gardens, where they are associated with perennials that are of such a robust constitution that they are able to look after themselves. Apart from the beauty of its orange red blossoms, a desirable feature of *L. croceum* (a feature shared by most of the upright-flowered Lilies) is that it will flower well the first season after planting, and does not need some time to get established as do several of the Martagon section. This renders it a trustworthy Lily for pots, in which I at one time grew it extensively, having to provide a number for the Orange Celebrations which occur at just about its flowering period. Another Lily which seems to me very reliable is one of the most beautiful of all, namely, *L. testaceum*, also known as *L. excelsum*. This Lily, of doubtful origin is exceedingly graceful, and in the mauve tint of its blossoms stands out alone. The tall, slender stems are of far more stability than one might think, though readily swayed by the wind. That garden group known sometimes as *davuricum* and at others as *umbellatum*, near relatives of the Orange Lily, are all reliable, perhaps the best being that known as *erectum*. *L. tigrinum*, too, is a good outdoor Lily. Of the Martagons the beautiful Japanese *L. Hansonii*, whose yellow, wax-like flowers are spotted with dark brown, differs from most of the section in being little, if at all, affected by removal; whereas most of this group take some time to become established. In soil largely of a vegetable nature and moderately moist, *L. pardalinum* does well and becomes thoroughly established. I am completely in accord with your correspondent concerning *L. szovitzianum*, that is, it is given a good, deep, loamy soil and allowed to remain undisturbed for it resents being moved.—H. P.

A BEAUTIFUL GREENHOUSE IRIS, *I. FIMBRIATA*, GROWN BY A READER AT ST. IVES, CORNWALL.

blooms in October. This may encourage other amateurs to try this glorious Lily.—(Miss) A. L. WAUD, *The Haven, Elstead, near Godalming*.

A Well-Grown Plant of *Iris fimbriata*.—I think you may be interested to see the photograph of *Iris fimbriata* which I enclose. I brought the plant from Rome some twenty years ago, and it has only bloomed in a very sparse way twice or thrice during all these years. You wrote me some two years ago as to its treatment, and this is the result, which is most satisfactory, and for which I have to thank you. It has been flowering for a fortnight, and will go on for another ten days, judging from the number of buds on the plant.—T. M. D., *St. Ives, Cornwall*.

Liquid Manure for Rose Trees in Winter.—In answer to Mr. C. Turner's note, page 103, issue March 1, asking for further light *re* above, he may be referred to Foster-Melliar's "Book of the Rose"—still the book for enthusiasts. If he will turn up the chapter on manures and also read the calendar of monthly operations, he will see such procedure advocated. Curiously enough, although not seeing Mr. Stevenson's notes, I chose the week they appeared to give my trees a thorough soaking,

form of the flower much resembles the *Incarvillea*, while the markings in the throat are similar to those of the *Pentstemon*. In the warmer and most sheltered of our Southern gardens it is said to live out of doors the year through. Propagation is by seed and cuttings.—C. T.

The Tenerife Broom (*Cytisus proliferus*).—

I was glad to see the reference to this free-flowering Broom in your issue of March 8, page 117. This little-known *Cytisus* is certainly worthy of extended cultivation as a pillar subject for a lofty conservatory, as instanced by the grand plant that may be seen in the Himalayan House at Kew at the present time. This specimen is clothing a pillar some 12 feet or 20 feet in height. The plant is wreathed with drooping inflorescences of creamy white, pea-shaped flowers. This *Cytisus* is a native of Tenerife, and in the warm parts of this country, such as Cornwall, it succeeds out of doors. In Nicholson's "Dictionary of Gardening" the height of this plant is given as 2 feet to 4 feet. When the trailing growths are trained to a pillar, as in the example referred to, there seems to be no reason why it should not attain six times that height.

Plants Flowering Early.—I have had *Prunella denticulata* flowering in an open border since early in January. I raised the plants from seed last April and planted them out in July. They did not die down, and were a month earlier in flower than those I potted and put in a cold greenhouse. The soil is medium, and I kept the soil very firm round their roots. My Apricots began to flower on March 1 on a sheltered south wall. *Saxifraga Griesbachii* is still in flower, with two large heads and a small one coming on.—M. W. SUGDEN, *Wells, Somerset.*

A Good Cabbage for Spring Sowing.—I am sending you a photograph of Cabbage Carter's Early Heartwell, which is the best variety that I know for spring sowing. As will be seen from the illustration, it makes a good-shaped head, and the flavour and texture are all that one can desire. If seed is sown about the end of March, good Cabbages will be ready for cutting during the early part of June. I notice that Messrs. Carter recommend it also for autumn sowing; but as I have never tried it for that purpose, I cannot say how far the recommendation is justified.—A. B., *Essex.*

Rose Lyon in New Zealand.—I have just been reading in a back number of THE GARDEN how the Lyon Rose varies under different treatment. I should like to tell you how mine behaved. It first flowered with a fine pink Rose, somewhat the colour of Ina Bingham; then on another branch it flowered the true Lyon—"shrimp pink and coral red." I think the catalogues say of it. On a third shoot it bore only coral red Roses; then the whole thing died. I suppose the effort to produce three distinct kinds of Roses at one time was too much for it. I hoped to save the coral red shoot, for I have never seen such a beautiful colour in Roses before or since; but I was unable to do so. I hope this may interest you.—E. O'CALLAGHAN, *Hawera, New Zealand.*

Daphne Genkwa.—On page 96 of issue February 22, Mr. Smith mentions this as the most captivating of the genus, and with that I think everyone who has seen it in flower will agree; it is one that should find a place in every garden where a suitable position can be found for it. Here it has withstood the winter in the open. A few other shrubs worthy of note which are sure to become more popular when better known are *Ceanothus Topaze*, a strong-growing variety, with clear blue flowers; *Cotoneaster Fontanesii*, a lovely plant for the autumn with brilliant red berries, about three feet high; *Cytisus kewensis*, a beautiful plant for the rock garden, with creamy flowers that appear about May. Unfortunately, the rabbits had a special liking for my plants this winter, for they were all eaten off to the graft before discovered. *Exochorda macrantha* has fragrant, snow white flowers which are very fine in the spring. *Philadelphus Virginalis* is a magnificent Mock Orange with fine white flowers. *Veronica hulkeana* is a good climber, planted under a south wall; it has stood the winter again and made good growth. It should have slight protection in very severe weather, and if planted where it gets drippings of water, should have a board or something to carry them off, as the shrub appears to suffer more from these than frost; it flowers in the spring, and the flower-spikes are pale lavender.—W. BEE, *Sumey.*

THE ROSE GARDEN. THE PRUNING OF ROSES.

I.—GENERAL PRINCIPLES

Study the Plants.—In order to prune well, it is, before all things, necessary that the gardener should have a clear idea of the object he wishes to attain and the probable means to achieve that end; and I should like at the outset to point out that for the end in view, theory alone will help but little if it is not combined with a careful personal study of the plants themselves. The habit of growth of the different species and varieties varies greatly; even in individuals of the same species differences of growth will be found, and each variation in habit probably requires some modification in the treatment to be applied.

The Objects in View in pruning are mainly three: (1) To secure the constant production of new wood and so prolong the life of the plant; (2) to obtain finer and better flowers than the plant would produce if left to itself; (3) to fit the plant for the position it occupies in the garden.

Now, the Roses in our gardens are plants in an extremely artificial condition. For the most part they consist of plants budded on the Dog Rose or other strong-rooting wild species. The means generally resorted to by wild Roses in a state of Nature for the production of new growth and perpetuation of the plants are not open to them in our gardens. An interesting illustration of this is recorded by Professor Crépin. He noticed that the American species *R. humilis*, which had once been very common in European gardens, had at one time nearly disappeared, and he found the explanation to be this: In its wild state this Rose pushes out long roots or rhizomes, which produce shoots destined to replace the principal plant, which usually perishes after languishing for some years. In cultivation these shoots have been cut off without much consideration of their place of origin, and so the plant, formerly very common, disappeared from nearly all gardens. To preserve this pretty little miniature Rose, he adds, these shoots must be carefully sought for and removed when sufficiently rooted and planted elsewhere.

This is, of course, an extreme case; but another illustration may be taken from the multiflora and wichurana hybrids, now so commonly used as climbers in our gardens. These produce straight or lax green shoots of considerable length which do not flower the first year, but the year following, from the axils of the buds along the greater part of their length, laterals or side shoots are produced, on which the flower-clusters are borne. Now comes the point. When these flowers are over,

this long shoot, which has turned brown, is finished so far as flower production is concerned. It is true that if the flowering laterals be left they will again send out shoots from their buds, which will flower in a third year, but no more flowering shoots will be formed immediately from the old stem. It is best, therefore, as a rule, to cut it away after it has flowered, leaving the plant to devote its energy to the fresh shoots of the year.

Hard, Barren Stems.—On old standards of Hybrid Perpetuals and Hybrid Teas, particularly those pruned on the long method, it is common to see the growing and flowering part separated from the stem by an ever-increasing length of hard, brown wood which has become useless for flowering purposes and serves only as a carrier for the growing and flowering parts. The longer this brown, flowerless wood becomes, the poorer, as a rule, become the growth and flowers at its extremity, and at the same time the stem itself is liable to attack by frost or fungus, so that it is only a question of time before it becomes necessary to remove it altogether.

In the case of standards, where specially large heads are desired, and for large specimen bushes, it is sometimes necessary to keep these long, barren stems; but, as a rule, for ordinary garden Roses it will be our object to keep as few of them as we can. We cannot, of course, permit our budded garden Roses to renew their young wood by the development of suckers, for this would

CABBAGE EARLY HEARTWELL, AN EXCELLENT VARIETY TO SOW NOW.

soon lead to the death of the budded plant; but we may properly make it our object to encourage the Rose to do the nearest permissible thing to this, namely, to have recourse to the constant production of strong young growths from the collar of the dwarf or the head of the standard just above the point of insertion of the bud. By the encouragement of young wood not only do we increase the length of life of the Rose, but at the same time we improve our chance of obtaining good flowers from our plants. The method we are to adopt to procure this constant succession of young wood must greatly depend on the position the plants occupy in the garden. It is not only

FORTHCOMING EVENTS.

March 28.—Beckenham Horticultural Society's Meeting and Lecture.

March 29.—Paisley Spring Flower Show.

by pruning back that this result can be attained, but also by thinning out weak shoots and pegging or bending down the strong ones. The pegging-down systems can be adopted where we have plenty of room at our disposal and strong-growing varieties to deal with. On walls or screens the strong shoots can be trained fanwise or more or less horizontally, while in the case of many of the Hybrid Teas grown as pillars, bending down the growths for a month or two in early spring is a convenient method of inducing the plants to break from the base. This may to some extent be assisted by careful syringing.

activity by pegging down are from one and a-half times to twice as long as those of severely-pruned plants of the same variety and the same age. A French writer once instituted a comparison between great growth made by a plant of Climbing Aimée Vibert allowed to grow practically unpruned on a house wall and a bed of Victor Verdier Roses, which, after being pruned by expert gardeners for twenty years, were found to weigh somewhat less than when first planted.

In both these cases pruning, far from increasing growth, has materially hindered it. It is, nevertheless, the fact that if we take two plants of

TREES AND SHRUBS.

SOME CHOICE HARDY CLIMBING PLANTS.

THE number of woody climbing plants suitable for the outdoor garden has increased enormously during the last few years; therefore it may not be out of place to direct attention to a few of the choicer and more useful kinds in order that those who are not well acquainted with them may be guided in their selections. As a rule, the kinds referred to may be expected to be hardy in all but the coldest parts of the country; but where there is a doubt about hardiness, it is mentioned in the description. In the selection no attempt has been made to keep strictly to new plants, for some which have been grown in our gardens for half a century are still among the most beautiful and most useful.

Actinidia chinensis.—This is a very vigorous, free-growing plant, and by far the best of the Actinidias. Introduced from China about twelve years ago, it soon became popular by reason of its large, heart-shaped leaves, which, together with the shoots when young, are covered with showy, reddish hairs. The yellow flowers are $1\frac{1}{2}$ inches across, and those of female plants are followed by edible fruits as large as a small Plum. It thrives in good loamy soil, and is an excellent pergola or trellis plant.

Akebia quinata is an older plant, but it is not met with so frequently as its decorative qualities deserve. Of vigorous habit, it may be expected to cover a large bush or a tree 18 feet to 20 feet high. Its five-parted leaves are very distinct, while its purple flowers, which appear in spring before the leaves, are borne in profusion. It is only when planted against a warm wall, however, that its violet-coloured fruit is ripened. A second species, *A. lobata*, is equally worthy of note.

Clematis Armandii.—This is a showy, white-flowered species which was introduced from China early in the present century. The flowers are usually borne in April, and they appear in good-sized axillary clusters, each flower being $1\frac{1}{2}$ inches to 2 inches across. Apart from the flowers, the plant is conspicuous by reason of its oblong, evergreen leaves, which are up to 6 inches long and 2 inches or more wide. It may be planted against a pergola, trellis, or wall.

Clematis montana rubens was fully described and illustrated in THE GARDEN for February 15.

Clematis Durandii should be planted in those gardens where difficulty is experienced in the cultivation of the ordinary garden varieties, for it rarely goes wrong in the way they do; it grows vigorously and bears its large, purplish flowers in profusion. The yellow flowers of *C. orientalis tangutica* make it an object of special interest, and it is well worth a position against the pillar of a pergola. A variety of the old *C. montana* also deserves a word of praise. This is *C. m. Wilsonii*. Its flowers are larger than those of the type, and many open during the autumn.

THE PERGOLA OF HARDY ORNAMENTAL VINES IN THE GARDENS AT GUNNERSBURY HOUSE, ACTON.

It may incidentally be mentioned that there are certain Roses, such as Maman Cochet and its white sport, which will naturally break from the base with very little encouragement. The growth, at first upright, soon bends over after the flower forms, and strong young basal shoots are readily formed. If there is room at our disposal, all we need do in these cases is to remove the old and any unripe wood when pruning. The amount of space the plant can be allowed will in such cases be the determining factor in guiding our operations, for with varieties of this character I have noticed in several cases that we get a greater vigour of growth when little shortening is practised than when the plants are closely cut back. This, however, can only be permitted so long as the plants continue to make good young shoots from the base of the stems.

It is often stated that one of the objects in pruning is to increase the growth of the plant; and some have gone so far as to suggest that where sufficient growth is made without pruning it should not be practised at all. Both statements require considerable limitation. I have found that, with nearly all varieties of very vigorous growth, the stems produced from the basal buds forced into

Hybrid Perpetuals or Hybrid Teas of the same kind and prune one lightly and the other severely enough to start the basal shoots into growth, the length and vigour of the individual growths on the severely-pruned plant will be decidedly greater than on that which has received little pruning, provided the plants are allowed to grow upright and in otherwise similar conditions, and this effect will be increased year by year if in subsequent years the same course is pursued with regard to the two plants. The object of pruning is, however, principally the production of flowers. Vigorous growth is only of incidental interest towards this end. It will be necessary to consider separately the various groups or classes, seeing that the Roses of different groups, and even the members and varieties in those groups, behave very differently in the matter of flower production, just as our demands on them vary, for in some cases we seek a few fine flowers; in others, many flowers, smaller, but well shaped; and in others, caring little for the individual flowers, we seek for a mass of colour in the garden. The appropriate treatment for these different groups and classes will be considered in subsequent articles. WHITE ROSE.

(To be continued)

Wistaria chinensis.—No list of choice climbers would be complete without this, for although it has been an occupant of our gardens for a very long period, it is still one of the most beautiful of all climbers. Of exceptionally vigorous habit, it is adapted for planting against high buildings or for covering good-sized trees, while, as it is amenable to severe pruning, it is well adapted for quite low walls and pergolas. After the required space has been covered, the object of the cultivator should be to secure as many stunted, spur-like growths as possible, for such growths continue year after year to produce a wealth of racemes of fragrant, mauve flowers. The white-flowered variety may also be planted, but neither the double-flowered form nor the kind with variegated leaves is recommended. *W. multiunga*, however, should be planted by all means, especially on pergolas, for its elegant racemes of fragrant, mauve-coloured blossoms are sometimes between 3 feet and 4 feet long. Its white variety is also very beautiful.

Jasminum primulinum is excellent for the milder counties, but is not sufficiently hardy for general cultivation. In places where it thrives it is quite as beautiful as the old *Jasminum nudiflorum*, than which there are few more showy climbers, while its golden flowers are larger than those of the older plant, and often have the curious hose-in-hose arrangement of the corolla, which is a familiar feature in some *Primula* flowers.

Hydrangea petiolaris is worthy of attention, for it is a neat-growing, self-clinging plant. It may be planted against a wall 15 feet or 18 feet in height, and a single plant may be expected to cover a space of 250 square feet and give little trouble except in guiding the leading shoots in the desired direction, and once a year pruning away any breast wood which is not desired. Flowers are borne freely during the summer in large, flattened heads. It is a native of Japan, and has long been in cultivation, although it is not widely grown.

Schizophragma hydrangeoides is a Chinese and Japanese plant closely allied to the above. It climbs in the same way, by means of aerial roots, and may be used for similar purposes. Another useful species may be obtained in *S. integrifolia*.

Celastrus articulatus should be planted where a vigorous climber is wanted for the wild garden or woodland, for it is only seen at its best when allowed to develop freely. It will ascend and cover a large bush or moderate-sized tree, and although of no account so far as flowers are concerned, it is very pretty in the autumn when covered with its orange and red fruits.

Vitis.—There are many excellent kinds of *Vitis* which are first-rate subjects for pergola planting (see illustration on page 144), but space will only allow of mention being made of *V. Coignetiae*, *V. armata* var. *Voitchii*, *V. leucoides*, *V. megadophylla*, *V. Thunbergii* and *V. Thomsonii*, with the showy-leaved *V. henryana* for wall planting. All must have rich, loamy soil.

Rubus, such as *R. flagelliformis*, *R. bambusarum* and *R. ichangensis*, have scandent branches, and

are excellent for the pergola and trellis; while the now well-known *Polygonum baldschuanicum* is excellent for planting against a large bush or small tree, over which its branches may ramble at will, for freely-grown examples usually blossom more profusely than those which have their growth restricted. D.

THE STAR-FLOWERED MAGNOLIA.
(*M. STELLATA*)

No garden is complete without this pretty shrub. It is the first of the *Magnolias* to flower, and this is a distinction very much in its favour in a mild spring, but ending in disaster in a very cold one. Unlike the well-known evergreen *Magnolia grandiflora*, so often used for clothing the walls of houses with warm aspects, the subject of this note is deciduous, and the flowers are borne from the latter end of March and through April before the leaves are fully developed. The starry flowers are pure white, and are greatly cherished for their sweet fragrance.

All *Magnolias* show a dislike for certain soils, and this may explain the reason why they are not more extensively grown. A good loamy soil of free and open texture is probably best, but, above all, it is important to plant in as warm a position as possible. *Magnolias*, again, are very impatient

THE HEATH GARDEN.

(Continued from page 134.)

HAVING disposed of the principal varieties of *Erica vulgaris*, those remaining are generally a little later in flowering, and, with one or two exceptions, are not recommended for planting in large quantities.

The Dorset Heath (*E. ciliaris*), however, makes a very effective mass about a foot in height, bearing pale red flowers, coming in a little later than *E. vulgaris*.

E. cinerea, sometimes designated the Scotch Heath, embraces a fair number of dwarf-growing plants, rarely exceeding 12 inches high, and mostly of red and purple shades. The type is represented by a neat little plant of about nine inches high, with purple flowers shading to lilac. *Alba* and *alba major* are the only white forms we have noted, the former being a fac-simile of the type, except in colour, the major form being slightly larger and later. *Atropurpurea* (9 inches), *atrosanguinea* (6 inches), *coerulea* (6 inches), *purpurea* (9 inches), *rosea* (9 inches) and *rubra* (6 inches) are pretty correctly described in the names they bear. *Spicata* is perhaps the tallest of this section, bearing long

A BED OF THE STAR-FLOWERED MAGNOLIA (*M. STELLATA*). THIS IS A BEAUTIFUL EARLY-FLOWERING SHRUB FOR A LAWN BED.

of removal, a characteristic that seems peculiar to the whole *Magnolia* family; the reason for this is found in the fine fibrous roots that are so easily damaged. Transplanting is sometimes a necessary evil, and in such cases the work should be carried out in the spring just at the time when growth commences, and not in the autumn, as sometimes advised.

Magnolia stellata is most effective when planted in large beds, the bright flowers lending pleasing brilliance to the landscape in the sunny days of spring.

spikes of a dull red, showing somewhat dingy when placed beside those already named.

A rather curious specimen is found in *E. scoparia*, the flowers of which are of a greenish hue; the plant attains a height of about two feet, and the flowers are distributed unevenly on longish spikes.

The Corsican Heath (*E. stricta*) forms a large bush about three feet in height, and possesses more of an upright habit than any of the genus. Its foliage is also especially attractive, particularly in the earlier stages of growth; the flowers are a

pale red colour, and are borne near the terminals of the shoots.

With *E. maweana*, a dwarf-growing variety, rarely more than 9 inches in height, and having flowers of a rich purplish red, which are usually at their best in the month of October, we would close our list of hardy Heaths; but another very interesting genus belonging to the same Natural Order is found in *Menziesia*, and which is usually included among the Heaths, having a similar habit and succeeding under the same treatment.

The Irish Heath (*Menziesia polifolia*, syn. *Daboecia polifolia*, the St Daboec's Heath, and perhaps better known as Irish Heath) is a very pretty plant, and quite as hardy and as free-growing as any of the Heaths. There is a purple and also a white variety each about a foot in height and of upright growth; the foliage is attractive, being a glossy green above and white beneath. The individual flowers are larger than any of the *Ericas*, and are drooping, the white form being very pretty.

M. empetrifolia, a synonym of *Bryanthus empetriformis*, is a neat little bush of about six inches in height; the flowers are reddish purple, and, being clustered near the extremities of the branches, produce a strong colour effect in the group.

M. caerulea, syn. *Phyllocladus taxifolia* (Yew-leaved), is somewhat scarce and difficult to get true. It possesses very shiny, green foliage, and flowers of a lilac colour. The *Menziesias*, when grouped in a bed according to height, have a fine effect, and make a pleasing contrast with the Heaths. All the varieties flower during summer.

Another excellent plant for the hardy Heath border is *Fabiana imbricata*, and, although belonging to the Order Solanaceae, it so much resembles the Heaths, both in foliage and in flower, that it may find a place among them. This has white flowers of exquisite purity, very freely produced on long branches during May and June. The plant grows to a height of 3 feet, and, having a somewhat erect, rigid growth with very attractive foliage, is always conspicuous. In cold districts it requires the shelter of a wall and protection during severe winters. The plant will thrive in light loam without the addition of peat.

It also makes a capital subject for the decoration of the greenhouse or conservatory when grown in pots. There are also numerous varieties of hardy Heaths, especially in the vulgaris group, that make excellent decorative plants when grown in pots, or at least transferred to pots from the open border before showing flower, and if suitable-sized pieces are grown for that purpose they will well repay the little attention they require. It is not claimed that they would rival such varieties as *E. gracilis* or *E. hyemalis* for indoor decoration, but where soil and climate are suitable, a large stock for the purpose can be economically obtained.

THOMAS WILSON.

THE GREENHOUSE.

NOTES ON CHRYSANTHEMUMS.

Exhibition Plants in March.—During this month, especially the latter part of it, cultivators will be very busy moving their forward plants into 6-inch pots, and the more backward of the early-rooted ones into 5-inch pots. In order to grow every variety to perfection, the cultivator should be well acquainted with the habit of them; but it is a fact that the most experienced grower fails to have all varieties at their best in any one season, so that it is wise to grow a few more varieties than

for this potting to leave as many lumps as possible about the size of a Walnut; the potting-stick will soon compress such lumps within the space allowed when potting is done. Furthermore, I prefer to sift out, through a quarter-inch mesh sieve, all the fibreless portion, and so retain the most fibrous. This sifting must be done gently, so as not to disturb the form of the lumps retained. Then sweet leaf-soil, road grit or coarse sand may be added to replace the sandless small lumps, which tend to clog the drainage if left in. I particularly refer to loam of a heavy, or rather heavy, nature. To every bushel of the above combined parts add a 3-inch potful of bone-meal, one of soot,

a 6-inch potful of wood-ashes, and chemical manures according to the instructions given with them, if these manures are favoured by cultivators. Ordinary firm potting is best; avoid undue pressure of the soil, and do not go to the other extreme and leave it too light. Pick out the plants so as to repot only those that are forward enough for the purpose.

Frame Treatment.—Undoubtedly the plants do better in cold frames at this season than in any heated structure. Much heat can be husbanded in a cold frame at this season from sunshine, but a too close atmosphere would result in a weakening of the growth. It is only advisable to keep the frame closed, or nearly so, during the four or five days following the potting of the plants. If the compost was in a medium state of moisture, watering will not be necessary for at least four days if the foliage is gently syringed twice daily on bright days.

Frame Propagation of Border Varieties.—Even an inexperienced cultivator need not hesitate to insert cuttings of border varieties freely either in boxes or the beds in cold frames now. It is better to put them in boxes, because the latter can be taken out of the frame for the hardening of the plants and the freeing of the frame for other kinds of plants in due time. Even if the old roots or stools look well in the borders now, it is advisable to root some cuttings, and those healthy-looking suckers are just the thing; none could be better. If the boxes are 3 inches deep, with holes or slits in the bottom for drainage, put in first a thin layer of rotted manure, then nearly fill the box with a sandy compost, and finally surface the firmed soil with coarse sand. Put in the cuttings 3 inches apart each way, water, and keep the frame closed for two or three weeks. The cuttings will soon form roots, and the young plants will be available for planting out early in May, when they should be given an open position and moderately rich and deeply cultivated soil. For autumn effect in the border these *Chrysanthemums* are indispensable.

AVON.

CARNATION DELICIA, A BEAUTIFUL WHITE-GROUND BORDER VARIETY WITH PINK AND CRIMSON MARKINGS.

are actually required on this account alone. Furthermore, it is a wise plan to adopt, because some varieties fail one season and succeed another, so that from the surplus plants good blooms are often obtained.

Potting Plants in March.—Some varieties do better in small pots, say, 9-inch ones, than in 11-inch, and in order to have all plants in such a condition that the work of potting can be done conveniently and in the best possible way, they must be grown on in pots of at least two sizes while young. The compost used now must be somewhat rougher—more lumpy—than previously. I like to pull the fibrous turf to pieces in every case, and

nothing could be better. If the boxes are 3 inches deep, with holes or slits in the bottom for drainage, put in first a thin layer of rotted manure, then nearly fill the box with a sandy compost, and finally surface the firmed soil with coarse sand. Put in the cuttings 3 inches apart each way, water, and keep the frame closed for two or three weeks. The cuttings will soon form roots, and the young plants will be available for planting out early in May, when they should be given an open position and moderately rich and deeply cultivated soil. For autumn effect in the border these *Chrysanthemums* are indispensable.

THE FLOWER GARDEN.**NOTES ON BORDER CARNATIONS.**

ALTHOUGH these plants are accommodating in the sense that they do not make heavy demands upon the time of the grower through the winter months, they will prove resentful of neglect. Therefore, whether the wintering is done in the open garden or in cold frames, the plants are always in some appreciable degree in one's mind.

It has steadily grown into a regular custom to place a portion of the stock in cold frames for the winter, because several of our most beautiful modern varieties have rather poorer constitutions than the old favourites, and, especially in strong, cold soils in a low-lying garden, the winter losses are apt to be serious. Their treatment all along must be that of hardy plants and not of tender ones, since if the latter course is pursued, trouble and anxiety are bound to arise sooner or later. Exclude torrential rains and heavy snow, but apart from that, see that the plants have all the fresh air and light that it is possible to afford them. This will spell slow and hard progress, and when the time arrives for planting, scarcely any bother and no worry will crop up.

If the positions decided upon have not yet been prepared for their reception, it is wise to attend to the task forthwith, because it is desirable that the soil shall settle well down after the deep moving that is so advantageous, and for the food virtues of the manure to become widely distributed throughout the ground. As far as the actual process of preparation is concerned, let it suffice to say that it is impossible to dig too deeply or too thoroughly, and the advantage of mixing rotten manure, well down, cannot be questioned, though one is opposed to the system which brings the manure in immediate contact with the roots. With the top spit it is sound practice to incorporate a generous dressing of crushed lime or mortar rubble, and if there is some old soot at command, work in some of it as well. The plants are most appreciative of both of these things, and their use tends to improve the flowers considerably.

As a rule it is wise to deter the planting until the end of the month in favourable situations, and until the first or second week of April in cold gardens where the soil is on the strong side. Meantime, let the plants be steadily hardened, so that they will not feel the slightest effects from the change of climatic conditions.

Plants that have passed the winter in the positions in which they are to flower usually thrive better than those that have to be disturbed, provided that the roots are in a friable medium and that they have been promptly re-firmed after the roots have been displaced by sharp frosts.

Mr. James Douglas of Great Bookham, Surrey, has most kindly placed the illustration on page 146 at the disposal of the Editor, and he describes *Delicia* as a fine representative variety of the fancy group; it has a white ground with pink and crimson markings. This leading expert also speaks most highly of Mrs. Elliot Douglas as a pure *Narcissus*

yellow self, and of Mrs. Griffiths Jones as a soft apricot self. Those who are wise will give the trio a good trial this season, procuring some for planting about the beginning of next month. F. R.

THE MULLEINS AND HOW TO GROW THEM.

THE *Verbascums*, commonly known as Mulleins, have been greatly improved during recent years. I know of no plants more noble or picturesque than the newer varieties. Their pyramidal spikes towering up among other border plants are just the very flowers which give the whole border a light, graceful and most natural appearance. The roots enjoy a good deep soil.

How to Propagate Them.—The Mulleins are easily propagated from root-cuttings. Cut the fleshy roots about two inches or three inches in length,

or sand. When the crowns of the plants often appear to be dead, the roots are still alive and in quite a suitable condition for propagating.

Varieties to Grow.—*Mars* is a most peculiar colour of buff, turning red towards the centre. *Caledonia* is a very effective variety. The colour of the flowers is sulphur yellow, suffused bronze. *Ivanhoe*, with its flowers literally packed on tall, branching spikes and of a deep rosy fawn, is very fine. *A. M. Burnie* is rose and bronze. One of the most distinct varieties is *densiflorum*. The foliage is quite distinct from any of the others, and is a beautiful light green. The spikes are not quite so dense as the above-mentioned, but of a more branching habit. The flowers are yellow, with a bronze orange centre. I consider this is one of the most attractive. The above-mentioned varieties all grow from 3 feet to 4 feet high.

A BED OF MULLEINS OR VERBASCUMS. THE PLANTS SHOWN ARE MOSTLY SPECIES AND ARE USEFUL FOR CREATING BOLD EFFECTS IN THE GARDEN.

taking care that the cuttings are kept upright; then place them about two inches apart in sandy soil in pots, pans, or boxes. Insert the roots so that the tops of the root-cuttings are level with the soil; then cover them with about a quarter of an inch of sand. Place them in a cold frame or greenhouse, sprinkle them with water occasionally so as to keep the soil just moist, and they will soon begin to shoot. Spring is the best time to propagate, though it can be done in the autumn quite successfully.

Protecting the Roots.—The plants sometimes die in the winter, but this is not because there is any deception as to their hardiness; but on account of their tree habit they sometimes flower themselves to death. When the stems are cut down, the plants can often be prevented from dying by placing over the crowns (during winter) some fibre, coke-ashes,

Tall-growing Varieties.—Three of the best tall-growing Mulleins are *Miss Willmott* (white), *phlomoides* (beautiful soft yellow) and *pannosum magnificum* (syn. *gloriosa*). The last-named is a giant species and a very noble plant. The foliage forms beautiful tufts during winter of a thick downy silvery white. It throws up large branching spikes to a height of 6 feet, which are literally covered with bright rich yellow flowers.

Graceful Hybrids.—*Wiedmannianum* and its hybrids are a very pretty, graceful-flowering section. They throw up slender stems from 2 feet to 2½ feet high, which are covered with flowers. The different hybrids vary in colour from white to palest rose, pale purple to the deepest purple, and deep rose to copper colour. Another which must be included is *Chaixii alba*. It has strong stems about three feet high, which are crowded with white flowers. J. L. E.

DAFFODIL NOTES.

DAFFODILS AT VINCENT SQUARE.

MARCH 4 AND 5.

(Continued from page 139.)

ONE hesitates about saying very much either for or against the latest comers when we only see them in their pot-grown condition. According to the doctrine of chances or the law of proportion, there will be

the small class, like Weardale Perfection, Firebrand and W. P. Milner, which revel in the kindly protection and warmth of a glass-house, and which are only seen at the top of their form when so treated; and there will be the larger class, where no appreciable benefit is gained from it, but, on the whole, probably rather the reverse. Will readers please remember this in perusing what follows. I may be damning with faint praise this, which, grown more naturally, would show quite a different face, or praising that, which, in the open, would certainly fall below the standard of excellence here presented.

I will deal with Messrs. Barr and Sons' group first, as all the blooms in it were grown in the open. During the day I had a talk with the secretary of the Breconshire Show, in the course of which she incidentally remarked that they had three climates in the county. I have since set myself this sum. If there are three climates in Breconshire, how many are there in England and Wales, and how many in the British Isles? I have nearly forgotten my algebra, but I have a dim recollection that there was a convenient "x" which one could put down to represent any unknown quantity. I unhesitatingly put down "x" as the true answer to my problem. Talk to a Devon man, as I did directly after my confab with the secretary, and he will tell you that his county is not Cornwall, and that North Devon is not South Devon. Then you might chime in, as I did, and say, "Neither is Cornwall Shropshire." Every single variety that I grow, and that was on Messrs. Barr's stand, was in the hard bud stage, or even hardly that, at Whitewell, when they must have been in their full glory at Rosemorrán. Even Lemon Princes and Alert were only just expanding on March 3. Ever since two men bought a £50 stock after reading something I had written in *THE GARDEN*, I feel I cannot be too cautious in what I say, and thus in the very forefront of another season's notes, which the Editor has again kindly asked me to supply, I call attention—I would it were with a megaphone that could reach every Daffodil enthusiast's ear to the enormous differences of climate which our flower has to live in when it finds a place in the gardens of the British Isles.

When you pause before some real beauty and wish it were yours, try to see in the leaves the signalman's green flag, and "proceed cautiously."

Probably by far the most attractive flower in Messrs. Barr's collection was Sunrise, which was shown in excellent condition. It is a lovely thing; the yellow in the perianth only adds to its beauty, and acts like a "softener" in a magic lantern. A representative of one of our most famous British firms, who is not much up in Daffodils, consulted me during the show about purchasing five or six goodish things for their autumn trade. "I want

toward their tips. It is very floriferous and is a quick increaser, equally good under glass and in the open.

In Messrs. Cartwright and Goodwin's group two varieties stood out pre-eminently. Neptune is an exquisite bicolor giant incomparabilis, which I can best describe as a "show" Lady Margaret Boscawen. The perianths of all in that vase would satisfy the most exacting judge. Maiden's Blush was the other one, a very ugly flower, but it was marked "Sold" early in the day. Why? There was an unmistakable pink edge to the short trumpet. Who knows but what this ugly duckling may be the progenitor of a pink-cupped race!

Messrs. W. T. Ware, Limited, had all their flowers in pots, one bulb in one pot. A little lot of Macebearer occupied the top centre. It always reminds me of my favourite Bernardino, but its petals are more formal, and its cup, which is shorter and more expanded, is banded orange-red rather than suffused. Diameter of the flower, $3\frac{3}{8}$ inches; diameter of the cup, one and three-sixteenths inches. White Nun is a taking giant Leedsii, of what I call the squat, well-groomed type; prim but pleasing. I was much taken with a recurvus-looking Poet with a rimmed eye, named Siena. The great difference in the widths of the alternate segments was very pronounced. I do not seem to remember such another. Princess Alice, as its name suggests, is similar in style to Princess Mary. The perianth, however, is a creamy white, and Mr. Ware assured me that its constitution was good, which is more than can be said of its namesake. It is by no means an expensive flower.

I liked Messrs. J. R. Pearson's small, dainty giant Leedsii Capella; Messrs. R. H. Bath's white perianth Barri Star of the East; and Messrs. R. Sydenham's new, almost triandrus hybrid-looking Leedsii White Frank (see illustration), none of them in the front rank as exhibition varieties, but delightful flowers. Mr. Bourne had several of these tip-toppers. He had some excellent Moonbeam, which struck me very much, as it is so very late—the white flag which heralds the summer truce after the heated battles of the shows. Next to it was a single bloom of an even whiter one, Alpine Snow, as white as any triandrus hybrid, and, of its type, *the* whitest in the show. Wendy is a refined flower after Mr. Bourne's own heart. Its distinction and charm lie in the wonderful deep apricot colouring of the expanded cup, which towards the edge passes to a decided buff (size of bloom $3\frac{1}{8}$ inches, by three-quarters of an inch depth of cup, by 1 inch width at top). A last word for his superb blooms of Whitewell. They quite rivalled in their depth of colour that never-to-be-forgotten bloom of Miss Currey's at Birmingham. JOSEPH JACOB.

NARCISSUS WHITE FRANK, A BEAUTIFUL NEW VARIETY SHOWN AT VINCENT SQUARE ON MARCH 4. (*Much reduced.*)

to show you one I would like, and I want to know what you think." I followed him as best I could in the crowd. He took me to Sunrise. "Ah," I said, "you are a pretty good judge of what's what; but if you could buy even a couple of hundred wholesale you would be a lucky man." It is a comfort to know it is a good increaser. I was glad to see Fairy Queen given a prominent place. It is a small, lovely, smooth-petalled little Leedsii, going quite white with age, with a sharply-cut-off cup and the perianth segments gracefully curving

GARDENING FOR BEGINNERS.

HOW TO DISBUD VINES AND PEACHES.

BOTH Vines and Peaches make rapid growth and produce young shoots in great numbers throughout the spring and summer seasons. If all the shoots that grow were left to mature, the Vines would become a tangle like Blackberry bushes on hedges, and the Peaches would be so overcrowded with them that neither the buds nor the fruits would colour and ripen properly. An inexperienced cultivator does not fully realise the importance of early and judicious disbudding, because he is misled by the sparse appearance of the tiny shoots. Early disbudding is essential to success. In carrying out the work the cultivator must not rush it through; that is, although he may be able to remove every surplus shoot in a single day, he should not do so, but only pinch out a few each day, and so spread out the work that it will be completed in about a week. There does not follow any check to growth of either branch or fruit left on when this system is adopted. In the case of Vines, the disbudding should commence when the young shoots are about an inch long, or when the tiny bunches can be seen in the ends of the shoots. It would be unwise to do the work before, as so many good-sized bunches might be sacrificed unintentionally. In the case of Peaches, the disbudding should be commenced directly the shoots are large enough to handle.

The Accompanying Illustrations will enable a beginner to understand more clearly how the work ought to be done. Fig. A shows at No. 1 a Vine rod, a few years old and bearing spurs, ready for disbudding. The shoots, Nos. 2 2, on the lowest spur are worthless and should be removed. The shoot, No. 3, is the one to retain; it bears a bunch of Grapes, which can be seen at this stage at the extreme end of it. On the second spur there are two good shoots, both bearing bunches of Grapes.

No. 4 is badly placed and should be removed. No. 5 is well placed in this instance and should be retained. Where there is only one young shoot on a spur, as shown at No. 6, and that spur is at the proper distance—15 inches, or nearly that—from others on the same side of the rod, it must be left to grow. No. 7 shows how the young shoots must be retained on a young Vine rod, No. 8 denoting the position from which surplus shoots have been removed. No. 9 shows a portion of a

Vine rod on which a young shoot, bearing a bunch of Grapes, has been duly "stopped" at the point. No. 10; then all the strength of the Vine goes to nurture the bunch and the main leaves. The sub-lateral shoots being stopped at the first leaf prevents any overcrowding of foliage. No. 11 shows the wrong way to remove a shoot—to disbud—and No. 12, the right. The young bunch can be seen under a glass, as shown at No. 13, but the leaves, No. 14, surrounding it must never be forcibly pulled back for the purpose, else they may be broken or torn. Fig. B depicts how Peach trees should be disbudded. No. 1 shows one-half of a newly-planted tree properly disbudded, and No. 2, the other half, not disbudded. The centre, No. 3, will always till up. No. 4 shows a large branch bearing both flowers and shoots. Nos. 5 5, denoting shoots and flowers, with crosses near them, must be pinched off. Nos. 6 6, those without crosses, should be left on to grow. A single shoot, or branch, properly disbudded of both flowers (where very numerous) and young shoots, is shown at Nos. 7 7 and Nos. 8 8 8 respectively. Where there are flowers in pairs, as shown at No. 9, with a shoot growing between, the shoot and flower, No. 10, on the under side, must be removed where there is overcrowding. No. 11 denotes a young shoot of medium size a few weeks after the general disbudding. It may be left unstoppped, and side shoots, Nos. 12 12, stopped as shown. The swelling fruit is shown at No. 13. No. 14 is a branch treated similarly to No. 11.

One of the most common errors made by amateurs in the cultivation of Vines and Peaches is that of leaving six shoots when there is only room for one. By following carefully the foregoing instructions the beginner will be able to carry out satisfactory the work of disbudding, which plays such an important part in the resultant crops. G. G.

THE WORK OF DISBUDDING VINES EXPLAINED. SOME GROWTHS ARE REMOVED AND OTHERS LEFT.

HELPFUL ILLUSTRATIONS TO THE CORRECT METHOD OF DISBUDDING PEACH TREES. (FOR EXPLANATORY NOTES SEE TEXT.)

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Tuberous Begonias.—For bedding-out purposes these should now be started in boxes in an intermediate house, or, where large quantities are grown, it may be wise to devote a slightly-heated frame to them. Here they may be just covered with light soil, and if given plenty of room to develop their foliage, may stay in the frame till planting-out-time, hardening them off as growth proceeds. From the boxes they will require potting off when nicely rooted, or may be planted in a cold frame.

Seedling Fibrous-Rooted Begonias should be pricked off as soon as large enough to handle, keeping them growing freely in a warm house or pit. This also applies to the seedling tuberous-rooted plants.

Pentstemons and Antirrhinums sown early in the season ought by now to have made sturdy little plants, and should be pricked off at once. When they have got well hold of the new soil, they may be removed to a cold frame.

Propagation generally must be proceeded with, getting in all the cuttings possible during the next week or two, as after the end of March there is not a great length of time for the young plants to grow and be hardened off before bedding-out-time.

Carpet-Bedding Plants may be rooted in the boxes in which they are to remain till planting-out-time.

Alyssum minimum is a plant much used for edging, and where it is raised from seed it may be sown at once, pricking off the seedlings into a cold frame when large enough to handle. Seedlings do not make such a nice even edging as plants raised from cuttings, but they are certainly much less trouble.

Annuals.—The present is a good time (providing the soil is fairly dry) to sow seeds of annuals either for cutting purposes or for garden decoration. Too thick sowing is not to be commended under any circumstances, the plants growing better and flowering for a much longer season when thinned to a good distance apart.

Plants Under Glass.

Hydrangea paniculata.—Plants plunged out of doors may now be pruned, bringing in a batch as soon as the basal buds have plumped up nicely. Though the plants will stand a little forcing, the best results are obtained when they are allowed a fairly cool greenhouse temperature.

Pelargoniums that are showing bloom should be well looked after in the way of water and manure, especially if in small pots, and as they are sometimes apt to become infested with green fly, a fumigation should occasionally be given. Specimen plants should be neatly staked out, leaving the stakes long enough to give an extra tie to the flowers as they push up well above the foliage.

Malmaison Carnations are now growing freely, and should be given a little more room to allow the side growths to develop properly. An 18-inch stake may be put to each plant, to which to secure the flower-spike as it pushes up. If well rooted, a little manure-water may be given, or a dressing of an approved fertiliser applied about every other week.

Shading Material.—Now that the sun is gaining power, it may be necessary to shade some of the more tender stove plants, as well as batches of plants recently potted. The flowering house is best shaded during the hottest part of the day, so that all blinds should be overhauled and placed in position at once. I am not an advocate of too much shading at any time, but in some instances it is quite necessary and helpful to the plants.

The Kitchen Garden.

Potatoes.—Maincrop Potatoes may be planted at any time now. Those for semi-early use need not be planted so far apart as those for late use. These latter should have at least 30 inches between the rows, especially in heavy soil, and, during the progress of planting, such soil should be well broken up with the fork, or it will mean a great deal more labour during the growing period previous to cutting-up. It is needless to mention varieties,

as nearly every district and garden grows some varieties better than others; but a thorough change of seed every year is extremely beneficial, and well repays the extra outlay.

Runner Beans.—For very early work a small batch should now be sown in pots, three seeds in a 6-inch or 8½-inch pot being a very good plan to adopt, and the latter will carry them quite a long time without them suffering, should the weather be unfavourable for planting out.

French Beans in pits will be growing freely now, and to encourage a stocky growth plenty of air may be given on fine, warm days. When they are near or touching the glass, a good covering must be given at night to ensure them not being injured by frost.

Fruits Under Glass.

Orchard-House Trees.—Plums and Pears, having now set their fruit, might be benefited by a slightly higher temperature, giving the trees a good syringing morning and afternoon on fine days, but sufficiently early to allow of them becoming thoroughly dry before night. A few of the early Apples may be coming into bloom, and if these are kept in a batch by themselves, fertilisation will be easier. Too much moisture at the roots is not necessary at this season, but it must be remembered that if they get thoroughly dry it is very detrimental to the setting and swelling of the young fruit.

The Hardy Fruit Garden.

Raspberries.—If not already done, these should be gone over and matting tied to the wires, allowing a fair distance between each cane. Where stakes are used, it may be necessary to renew them, using good, strong Hazel or Ash stakes which have been prepared beforehand by tarring the bottom for at least 18 inches. These being surface-rooting plants, they should not be deeply forked between, but a little short manure may with advantage be lightly pricked into the surface of the soil.

THOMAS STEVENSON.

(Head-gardener to E. Moratta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Sweet Peas.—These, whether in pots or boxes, must have an abundance of air and light to prevent the plants from becoming drawn and weakly. In fine weather the lights of the frame should be removed entirely.

Sweet Williams.—Self-coloured varieties of these, such as Sutton's Pink Beauty, are very telling when planted in masses, and where they have been wintered in the reserve garden, they should now be planted out, taking care to lift the plants with good balls of soil.

Canterbury Bells.—These biennials are among the most showy of our summer hardy flowers, and should not be overlooked. Planted out now with good balls of soil, they will commence flowering early in July.

Pansies and Violas.—The sooner these are planted out, the sooner they will begin to flower. It is advisable, as far as practicable, to plant them in fresh quarters annually. We have been for several years planting a certain variety of Viola as a groundwork among the bulk of our Roses. All has gone well up till the present, but nearly the whole of the young stock have died during the winter; while of other varieties which have had their summer quarters changed regularly, hardly a plant has perished. The lesson is obvious.

Shrubby Veronicas.—There are a number of barely hardy shrubby Veronicas which deserve attention, such as *V. salicifolia*, *V. Andersonii*, *V. A. Diamond* and so on. If they have been hardened off, they may now be planted with safety. They can either be associated with herbaceous plants or planted immediately in the front of the shrubbery. *V. Andersonii variegata* is a useful bedding plant, and looks well in conjunction with *Salvia patens*.

The Rock Garden.

Scented Plants.—A few of these should find a place in every rock garden, but variety could be obtained by devoting a portion of the rockwork wholly

to these. In the higher reaches Lavender, variegated Mint and Balm could be planted, and, further down, the Sweet Marjorams and Santolinas, finishing at the base with Thymes, dwarf Menthas and *Micromeria Douglasii*.

Plants Under Glass.

Repotting Palms.—Palms, being largely used for the decoration of rooms and corridors, should be grown in as small pots as possible, and with careful watering and judicious feeding they will do with less root room than most plants. Potting must be had recourse to from time to time, however, and the present is a good time to carry out the operation.

Phyllanthus roseo-pictus.—So far as I know, this is the only member of the genus which can be called showy. Its delicately-tinted, graceful foliage, however, well entitles it to a high place among our stove plants. It is easily propagated by cuttings in heat, is not particular as to soil, but prefers a sandy loam, and, so far as my experience goes, has no enemies. If regularly cut well back in spring, a bushy habit will be formed, and the plants will be serviceable for many years.

Cyclamens.—Seedlings, the result of an August sowing, should now be ready to pot off into 2½-inch pots. Use equal parts of loam, good leaf-mould and sand; lift the seedlings carefully, pot rather loosely, and only half cover the combs when potting. Spray twice daily and shade from bright sunshine.

Shading must now be provided for the various plant-houses, although cool houses should receive attention last. Where time and expense are no barriers, movable shadings should be used; but in most establishments fixed shadings are the rule. A useful shading can be made from sour milk and whiting. Newly-slaked lime does very well, but should not be allowed to come in contact with the putty. When applying, form wavy lines in preference to straight ones.

Fruits Under Glass.

Thinning Peaches.—This work must be carried out with discretion. A strong-growing variety will bring to perfection more fruit relatively than a weak one. This principle holds good with trees of the same variety, and once more the principle holds good with regard to different shoots on the same tree. Commence the operation when the fruits are about the size of small marbles, and if fairly well placed, retain the largest fruits. Be careful not to tear away a portion of the bark. Give the fruits a sharp twist and pull towards the point of the shoot.

The Hardy Fruit Garden.

The Black Currant Mite.—It is to be feared that no thoroughly efficacious remedy has yet been found for this destructive pest. If, however, the opening buds are dusted three times between this and the end of April with one part ground lime to two parts of flowers of sulphur, the mite will be well kept in check. The bushes should be damp when the mixture is applied.

Looking Ahead.—The stock of netting should be overhauled and augmented if necessary, as it may be requisitioned on short notice when spring frosts occur while Pears, Plums, Apricots and Cherries are in bloom.

The Kitchen Garden.

Turnip-Rooted Beet.—It is too early yet to sow the main crop of Beet, but a sowing of a Turnip-rooted variety should be made for early use. Several firms now offer varieties superior to the old Egyptian variety. For this class the drills need not be more than a foot apart.

Planting Cabbages.—A planting should now be made from those sown in the autumn. A good plan is to plant a batch of an early variety, and a batch of Wimmerstadt to succeed it before the spring-sown stock turns in. Give the autumn-planted batch another dressing of nitrate of soda or old lath-manure and stir with the Dutch hoe.

Lettuces.—Give the autumn-planted stock a dressing of soot and stir with the hoe. Make another sowing. All have their favourite varieties. We use little but Neapolitan for the main crop; if a Cos variety is wanted, Paris White Cos is hard to beat.

Celery Trenches should be formed and manured when time will permit. CHARLES COMFORT.
Broomfield Gardens, Davidson's Mans, Midlothian.

ROCK AND WATER GARDEN.

MY FIFTY ALPINES.

THE problem of exclusion, so bravely tackled by Mr. Arnott in THE GARDEN for March 1, is one of intense interest. In all such lists and choices there is bound to lie a challenge to other gardeners and different tastes. It is hardly to be thought possible that I in particular could sit quite quiet, in patient peace, beneath a selection which finds no room for Dianthus alpinus! And I trust that Mr. Arnott's choice will stimulate other gardeners also to give theirs. At the same time, it must be understood that I do not in any way cavil at Mr. Arnott's selection. It is the charm of such selections that they are almost bound to elicit the views of other people. Each gardener has his special favourites, to whom he burns to see justice done (and bravo, Mr. Arnott, for putting Ranuncula Nataliae instead of the commoner and dowdier R. pyrenaica). Therefore will I come forward, not to attack Mr. Arnott, but to break a lance or two in favour of some of my especial loves omitted in his list.

The plants to be chosen, let us postulate, must all be of easy and robust growth in any garden, great or small, under reasonable conditions of culture. Shrubs, with one or two exceptions, are to be excluded. And also, as the field among bulbs is as vast as that among alpinos, I think it is hardly fair, in a choice of rock plants, to run the risk of having to crowd out here and there a treasure to make room for such and such a no less treasured bulb. No, it will be (and has, alas! been) hard enough to make a selection among fifty alpinos; if bulbs are to be thrown in, there will be weeping and gnashing of teeth indeed. Of bulbs and monocotyledons for the small rock garden, let us now have a separate list, please, Mr. Arnott. It will be very easily filled up, and will need hardly less drastic selection than the other. Iris and Crocus alone will bring up many fierce rivalries, and half crowd up the list already. No bulbs, then, no annuals, no shrubs as yet (except the indispensable) and, above all, a prolonged season from spring to autumn.

Now for the personal excisions that I must make from Mr. Arnott's list. Out goes Adonis amurensis, a lovely thing as you see it in a Japanese bog garden, just a golden button on the earth and no more; in gardens, of a shrill and venomous green-tainted yellow, like that of so many poisonous Ranunculads (but compare the pure and bland citron of Trollius), and in habit rather ill-bred, to my taste, in its development. I question next Arnebia's claim to front rank, and I do not expect my list will be able to afford more than one Aubrietia, for certainly more Campanulas will be wanted. Erica carnea, again—good, pleasant thing—is "general utility" rather than a first choice. Galax aphylla is surely quite low down among one's loves; not by any means a plant to include at the cost, say, of Gentiana acaulis. Then comes Hypericum fragile, not to be compared, in my eyes (pace Sir Herbert Maxwell), with either H. reptans or H. Coris. After this I chiefly supplement Mr. Arnott's list, though I cannot set pretty, commonplace, useful Silene Schaffa among my first fifty beloveds. Synthesis hardly seems of first rank either, and Shortia galacifolia, though lovely, certainly yields in beauty to S. uniflora grandiflora, and neither is of universally easy culture; at least, I trust there are some gardeners who share my perpetual

inability to make either of them seem really happy. At this rate, if Shortias are to come in, where is Schizocodon, which, at its best, is lovelier than either? Finally, the great races are too scantily represented. Where only two Campanulas are allowed, it is surely unjust to sacrifice indispensable pusilla or amenable Allionii to the stout and comparatively dowdy-coloured garganica hirsuta; and the great silver Saxifrages in themselves are winter furnishing far above Erica carnea.

But the task, however you achieve it, is a cruel and terrible one. I may say that my first choice of fifty absolutely indispensable plants that no gardener in his senses could possibly live without amounted in the end to ninety-five, and the anguish of reduction beggars language. Even then, when one has mingled one's choice into the required limits, there are bound to remain a certain number of tiresome "utility" plants, such as Gypsophila repens and Saponaria ocyroides (or lovely Anemone Hepatica as an early bloomer), that have to be kept in (or ought to be kept in, if one has the heart) at the cost of Campanula Elatines, C. Rainieri and C. Zoysi, or Saxifraga retusa, S. cochlearis and S. longitoba. Not that one is within a hundred miles of liking them so well, but because they can be relied on always for a fine and large display of a commonplace, brilliant nature, under commonplace treatment and conditions, just like any Knotgrass or Goatweed. (For at this moment I hate them heartily and grudge their very existence.)

With regard to the soil mixtures, I believe that, as Mr. Arnott says, a good, light compound will suit nearly all alpinos. Where I have suggested lime, it is not because lime is clearly necessary (as it almost is, I believe, for Gentiana "Gentianella"), but because the species attributed to it seem specially faithful to it in Nature, as, for instance, the Arthritic Primulas, constant to peaty soil on the high limestones, as against P. minima from the same peaty turf, but quite indifferent as to its underlying rock. With regard to aspect, again, each garden and climate has to discover its own rules. I have merely suggested such conditions as seem to answer here in an alpine climate, cool, wet and cloudy. The rules I have hinted at have been, however, as universal as possible. Sempervivum and Papaver, for instance, are universally unfavourable to shade and damp and heavy soil. In cases where I suggest an open aspect, it may be found that in hot, Southern gardens a less torrid position may be better. And now, please, let someone else come forward with another list of fifty indispensable alpinos, or, perhaps, a secondary list, to include the forty-five irreplaceable treasures that I have had to excuse, with breaking heart, from the first choice of universal and glorious rock garden plants.

REGINALD FARRER.

[We shall be pleased to receive further selections of alpinos from readers, or criticisms and comments on Mr. Farrer's and Mr. Arnott's selections.—ED.]

Table with 7 columns: Name, Height Inches, Aspect, Soil, Colour, Flowering Period, How to Propagate. Lists various alpine plants like Aquilegia glandulosa, Androsace lanuginosa, Anemone sylvestris major, etc., with their characteristics and propagation methods.

NOTES ON THE GARDENING ACROSTICS.

THE acrostics are over and the prize-money has been distributed, and we now publish our promised comments. First let us say that we hope they have been acceptable to a good many of our readers, even beyond the number of those who attempted their solution. The short explanatory notes of most of the "lights" were specially printed, in order that, if possible, it might be so. The following extracts are from two of the last letters received on the subject: "I am very pleased to see you are going to give another series next winter." "I almost wish the end of the year had come again so that I might tackle some more of your puzzlers." Such will be the case, we hope. Profiting, however, by our experience, readers will find certain changes. The questions will not be so difficult on the whole, and the marking will be different. Instead of each acrostic counting one and there being no sliding scale between absolute right and absolute wrong, each "light" correctly solved will count 1, and each "firsts" and each "lasts" also 1. Thus, to take No. 1, "China Aster," the full marks would be 12. We quite see that it is hard to count nothing when, as in No. 2, so many had all right except the vineyard "light," which should have been Hoxton, but which a large proportion gave as Hatton Garden. Our "puzzler" is not intallible, and sometimes, either intentionally or unintentionally, he is vague; hence the wisdom and fairness of our proposed amended marking. It will also, we hope, promote increased competition, inasmuch as it will be quite worth while to send in partly-completed solutions, which in the last competition were valueless.

The "difficult" question is not so easy of solution, but we have the satisfaction of knowing that our "Saint Worrier" (to use a name given him by a very well known old-time Liverpool cricketer on account of his blocking tactics in the days of his youth) knows how to temper his worryings to the library opportunities of our readers. Another season's acrostics will not be so severe, although we may have to call in some "Senior Wrangler" to help us in our fractional calculations when the prizes are sent round. There will be eight acrostics, or possibly ten, and if between now and next November any scheme strikes us as feasible by means of which we might make two classes of competitors, we will certainly try it, as our wish is to give as many as we can of our readers at least a "sporting chance" interest in them. We take the acrostics *seriatim*.

No. 1.—No fewer than 172 solutions were sent in, of which 111 were correct. Our acrostic writer got frightened and thought he was too easy, and Nos. 3, 4 and 5 were the result. In the last named only twelve solutions were sent in, and every one was wrong. "Ironwort" was put for "Indian Shot," and "Arbour" or "Arbor" for "Alder."

No. 2.—The stumbling-block was the locality of the vineyard. One hundred and thirty-seven solutions were sent in, and only fifteen were correct. Hatton Garden was a favourite locality, and Walford's "Old and New London," Vol. IV., page 4, was quoted in support.

No. 3. A great falling off. Only thirty-seven sent in, out of which but four were right. The "difficult" plant was variously given as *Iris hiberna* and *I. reticulata*. These would fit in

and would come under the head of "difficult," but *Iris susiana* was the plant intended.

No. 4.—This was undoubtedly too hard. There were fifteen solutions sent in, and only one was correct. We congratulate "White Lady" on being that one. "Singers of an 'O'" puzzled nearly everyone. *Pelargonium* would have done just as well as *Palm*; but we had to keep to our rules.

No. 5.—Twelve attempts were made to solve this, and not one succeeded. Olive in the majority of cases was given as the well-known "green." We cannot find much about it in comparison to the Orange, and would be grateful for a note on the relative importance of the two from any of those who put it as their solution. "Simpling" was a stumbling-block in several cases.

No. 6 was much easier, and out of twenty-two sent in, fourteen were right.

No. 7.—Sixteen solutions came to hand, of which six were correct. Several put *Hepatica* for *Henna* as Mahomed's Flower of Paradise.

No. 8.—This was purposely difficult. We have had several letters asking why "Le Jardin de Hollande" should be translated "The Dutch Gardener." The one is not a translation of the other, but they are both the chosen titles of the French and English editions of van Oosten's little Dutch book on bulbs.

With these brief notes we conclude our acrostic season of 1912-13. If, on reading the foregoing, readers have any suggestions to make with a view to our going "one better" next time, we would be glad to hear from them.

THE KITCHEN GARDEN.

SEASONABLE NOTES ON VEGETABLES.

Potatoes.—In most gardens the earliest Potatoes have been planted for some considerable time, and the chances are that they will demand careful watching to prevent injury or perhaps ruination. Although a position is chosen with a warm aspect and preferably where the soil is light, it is unwise to conclude that no frost of sufficient severity to cut the tops will occur. Have immediately at hand enough light protective material with which to cover the plants, and one may then feel reasonably secure. It is by no means amiss to give 1oz. of nitrate of soda to each 3-foot run of drill just before the first earthing is done, as it tends to encourage finer stems and leaves. The second-early varieties, which will be planted directly the soil and weather are favourable, ought to have wider spacing between the lines, because they grow more strongly and to facilitate passage down the alleys when the time comes to take preventive measures against the disease. As a general rule, 27 inches should be allowed from row to row, and a distance of 14 inches should be given between the sets in them. Each tuber ought to carry two excellent, hard, deep green sprouts to ensure a splendid plant; or, if the tubers have not been prepared, let the shoots be reduced to two with the same object. Drilling in is much preferable to dibbling, and it wood-ashes are at command, scatter some before the seed sets are placed in position.

Sowing Tomatoes.—A common error made by amateurs whose equipment of frames is not complete is to sow their Tomatoes for outdoor culture too early. Where there is only one structure, the middle of April is early enough; but where

there are two of different temperatures, seeds may be sown between the present date and the end of the month. To achieve success it is imperative that the plants shall be hardy and sturdily grown, and the earlier the sowing is accomplished, the more trouble is involved in keeping them in that state. If sufficient small pots are available, sow one seed in each, as this precludes the possibility of root disturbance; if not, sow very thinly in pans or boxes to obviate the necessity of any thinning and to make the task of moving much easier without giving the slightest check. The slower the rate of advance, provided there is no complete stoppage, the better the plants will be.

Successive Peas.—The good grower of vegetables regards an unbroken succession of Peas as a necessity. He is by no means satisfied when he produces exceptionally early or extraordinarily late crops, unless he has had plenty of perfect pods in between times. With a view to securing this he makes sowings at frequent intervals of his favourite varieties, and he fervently hopes that the weather will not develop that peculiar phase which upsets all human calculations. An excellent rule is to sow a fresh row immediately its predecessor is through the ground. The drills should be shallow, flat-bottomed and firm, and the seeding, after heavily coating with red lead where mice cause worry, must be thin to economise seeds and labour, and favour a sturdier, far more prolific plant.

Winter Greens.—The earliest sowings of Brussels Sprouts, and perhaps of other kinds, too, have long been made; but green crops must be available from early in the autumn until late in the following spring, and seeds must, therefore, be sown in batches. Between the present date and the middle of April, according to the soil and district, the principal sowings will be made. Specially-prepared beds for the seeds are desirable, if not necessary. It is customary to select a position on a warm border the soil of which is thoroughly dug to the depth of at least a spit, and with the top 8 inches may advisedly be mixed a generous quantity of refuse manure or flaky leaf-mould. Such material as this is appreciated by the tender roots, which cling to it with considerable tenacity and thereby favour transplantation with a ball of soil attached. Thin seeding and early thinning are details of paramount importance.

Broad Windsor Beans.—A sowing of a good strain of Broad Windsor Beans must be made towards the end of the month. It cannot be claimed that these Beans have the same conspicuous importance as Peas in the vegetable quarters, but in no circumstances must they be omitted. Double lines are usually preferred to single ones, and the flat-bottomed drills, 3 inches deep in most soils, ought, therefore, to be 10 inches or 12 inches wide. Place the seeds 3 inches apart along each side 1 inch from the edge, and later thin out to 6 inches asunder in both lines for fruiting. This allows plenty of air space and profitable plants result. H. J.

TRANSPLANTING ONIONS.

By this time all preparations should be completed for transplanting autumn-sown Onions. Too much stress cannot be laid upon the fact that the Onion is one of the deepest rooting vegetables we have, and in consequence responds to deep cultivation. The young bulbs should be planted 6 inches apart in rows with 14 inches between the rows. It is found that transplanted Onions are less liable to the attacks of the much-dreaded Onion fly.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

NOTES OF THE WEEK.

Potatoes in 1912.—According to the Annual Returns of Crops just published by the Board of Agriculture and Fisheries, the Potato crop in 1912 was the lowest on record, the average yield being 484 tons per acre, the previous lowest figures being 497 tons in 1900. Owing to a larger area being under Potatoes in 1912, the total production was not the lowest on record, though it was nearly 670,000 tons less than in 1911.

A Beautiful Colour Combination.—A very charming colour combination that might advantageously be carried out in many gardens was mentioned by Mr. Dillstone, of Messrs. R. Wallace and Co., when lecturing before the Chelmsford Gardeners' Association recently. This was a broad belt of Lavender, interspersed at intervals with groups of pink China Roses. The broad belt could, of course, be modified, the main idea of combining lavender and pink always being borne in mind.

The Pasque-Flower.—In the gardens at Lauriston Hall, Kirkeudbrightshire, may be observed quite a number of fine plants of the Pasque-flower, *Anemone Pulsatilla*, growing in the ordinary border. It is quite apparent that both the climate and soil suit this Windflower there. The sod is a loamy one, and there is no lime or other calcareous matter in it. The situation is naturally elevated, but the garden lies in a slight hollow, and is inclined to be rather damp and late, this being a somewhat cold part of the Stewartry and known as the "Southern Highlands." It is interesting to see this plant doing so well in such a situation.

Transplanting Laurustinus.—Anyone desirous of transplanting this well-known winter-flowering shrub will find the present time most suitable, and if care is taken, very little check will be given. It is needless to mention that as much soil as possible should be kept on the roots; but if they have been cut to any extent, it is advisable to remove some of the shoots to give the plant a more equal balance. A mulching of manure and occasional syringing, particularly in dry weather, will be found very beneficial. Little pruning is necessary for this shrub when once established, except to keep it in shape; this should be done after flowering.

A Charming Hard-Wooded Greenhouse Plant. Unfortunately, the many showy Australian shrubs which were so popular in glass-houses in this country about the middle of last century have almost disappeared from our gardens, and, with the exception of the Acacias and a few other plants, we rarely see them now. Yet when anyone does produce a well-grown and well-flowered group of these old-fashioned plants there are always plenty of commendatory notices. Quite recently we noted a few excellent examples of *Chorizema varium*, or *C. Chandleri* as it has been sometimes called. The plants were 2 feet to 3 feet high, and composed

of from six to eight branches each, every branch being divided into numerous branchlets, each one bearing many racemes of the pretty orange and red Pea-shaped flowers.

The Double-Flowered Gorse.—The various groups of double-flowered Gorse which are to be seen about the river end of the Syon Vista at Kew are a good object-lesson as to satisfactory clothing of dry, stony banks, for at the present time they are a wealth of golden blossoms, and will continue showy for several weeks to come. The positions in question are built up with sandy gravel which has been excavated at various times from the lake, and the material is wholly unsatisfactory for the cultivation of many choice trees or shrubs; yet with no particular attention the Gorse grows and blossoms well.

A Pretty Shrubby Aster.—For several weeks past a shrubby Aster has been flowering well in the Temperate House at Kew, where it has been one of the most noticeable of the uncommon plants. The species is *A. fruticosus*, a native of South Africa, and although grown in English gardens as long ago as 1750, it may now be considered to be practically unknown to the general horticulturist. Forming a plant 2 feet or so in height, the branch system is made up of numerous wiry branchlets, which are clothed with small, linear leaves, and terminated during late winter and early spring with solitary flower-heads half an inch to three-quarters of an inch across, the ray florets being mauve and the disc florets yellow.

Dressing Tulip Flowers.—A fashion has lately sprung up in Holland of dressing the flowers of Darwin Tulips by turning the three outer perianth segments back and leaving the three inner ones standing upright. We are told that the reason for this practice is that the beautiful colouring of the interiors may be seen. This object is partly obtained, but at the cost of the distortion of the flower. We have noticed a few blooms treated like this at the Royal Horticultural Society's shows, and we cannot say they appealed to us. Why torture the poor Tulip thus? Was it not enough to see the wretched *Nelumbiums* so maltreated last year? It is difficult to improve upon Nature's own way of showing her gems.

Azara microphylla.—This Chilean shrub makes an excellent plant for training against the walls of houses. We do not think its good points when used in such positions are as widely known as they might be. We know a house as far North as Cheshire which is partly covered with this *Azara* on its south and west aspects. It has been there for about twenty years, and in the hardest winters nothing worse has happened than the blackening of the ends of the longest shoots. As, however, it does not mind the knife, and as it breaks again very freely before the summer is far over, the damage is quite obliterated. It is covered with small, inconspicuous yellow flowers in March or early April, which emit a Vanilla-like scent.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

The National Daffodil Society.—Our letters in THE GARDEN have acted as a poker; the Narcissus committee has been stirred up and is now blazing away furiously, as you will see from my notes on page 103.—JOSEPH JACOB.

Gunnera manicata and G. scabra.—When these handsome water-side plants begin to deteriorate, which they will do in course of time, it is a good plan to move them to another place. The best time for the operation is March or early in April. A good piece should be taken from the old plant with as much root attached to it as possible, and carefully planted in some good, rich soil. If possible, a good mulching of cow-manure should be given; in fact, this will be found very beneficial to the plants at any time. Much finer leaves may be obtained if the flower-spikes are removed as soon as they appear.—H. C. P.

Tarragon.—To obtain healthy young shoots of this much-called-for herb, a fresh bed should be made yearly large enough to meet the demand. It is a native of Siberia, and readily multiplied by division, or by pulling up young pieces when about three inches to four inches high and dibbling them about four inches apart in well-prepared beds. Water the soil well if the weather proves dry. There is a plant sometimes grown which greatly resembles the Tarragon. I grew it many years ago, but it was quite destitute of the real Tarragon flavour, and I was obliged to obtain the right kind from a good firm, after which I experienced no further difficulty in maintaining plenty of the true variety.—H. MARKHAM.

Snowdrops in the Grey Moraine.—A remarkably pretty sight here has been a good group of one of the finest of the hybrid Snowdrops at the top of a grey whinstone moraine, at the base of a small wall planted with alpinists. This Snowdrop is called Anne of Geierstein, and is one of a set of hybrids raised by a Lanarkshire amateur between *Galanthus plicatus* and *G. invidiosus* a number of years ago. It is tall, and has large and shapely flowers of the purest white, save where that is relieved by the usual green markings. Against the wall, and at the top of this grey moraine, associated with Saxifrages, Dianthus and other plants, this Snowdrop is most beautiful among the grey whinstone chips which surmount the moraine. We are beginning to see how long a period of grace will be given by the moraine, when we find that many of the bulbs do so well in it. With the earliest Saxifrages, Snowdrops, Scillas, the smaller Narcissus and so forth, the moraine may be a perfect picture in early spring.—S. ARNOTT, *Dumfries*.

A Beautiful Blue-Flowered Greenhouse Shrub.—Flowers of a bright and attractive shade of blue are always admired, either indoors or out. In the greenhouse blue flowers are not at all numerous, and among the shrubby occupants of this structure *Leschenaultia biloba major* stands out almost alone. The general aspect of this *Leschenaultia* is that of a Heath, but the leaves are thicker and more fleshy than those of Heaths. The flowers, which are freely borne in loose clusters at the points of the shoots, are about an inch across and of a lovely shade of blue, somewhat deeper when first expanded than they are later on. This *Leschenaultia* needs much the same treatment as the greenhouse Heaths, and, like them, it was formerly grown as a specimen plant. It is a native

of Australia, as, indeed, are all the other members of the genus. The last exhibitors of *Leschenaultia biloba major*, at least in quantity, were Messrs. Balfour of Brighton, who at that time had a branch nursery at Hassocks, where they flourished not only this *Leschenaultia*, but many other almost forgotten hard-wooded plants, all of which grew luxuriantly in the pure air of the South Downs. What is more, the blossoms under these conditions acquired a depth of colouring such as one rarely sees elsewhere.—W. T.

Early-Flowered Indian Azaleas.—A variety of this class of Azalea which has become very popular of late years is *Mme. Petrick*, whose distinguishing feature is the early season at which it may be had in bloom. It is of good habit, and the flowers, which are freely borne, are semi-double and of a deep rose colour. Where these Azaleas are required early, the merits of this variety must on no account be overlooked. The best of the double or semi-double whites for early flowering is, and has been for a long time, *Deutsche Perle*, whose blossoms are particularly pleasing when partially expanded, as they are then just like tiny Rosebuds. Another early-flowering variety which has come prominently forward during the present season is *J. B. Varome*. It belongs to a section of these Azaleas which has of late years gained many admirers; that is to say, those whose flowers are of a salmon or rosy salmon tint, with a light-coloured margin and, in some cases, a pale centre. In *J. B. Varome* the salmon is more pronounced than in some of the others, the result being a pleasing flower. Its most prominent desirable feature is, however, the fact that it blooms earlier than any others of its class.—H. P.

Mr. Lester Morse on Sweet Peas.—I had not intended to address you on the subject of the necessity of tackling the question of Sweet Pea nomenclature, because I was interested to read the opinions of the lay public and wished to see in what direction the trend of opinion might lead. The mention, however, of two of my varieties by Mr. F. Herbert Chapman in your issue for March 15, page 130, makes me think it may be opportune to offer a few remarks. If the floral committee of the National Sweet Pea Society were a strong body, it seems to me that it would be a simple affair to grow all the 600 "varieties" and reduce them straightway to less than 200, and give names by priority of introduction or, in cases of doubt, by lot. With the help of local horticultural societies it would be possible to ensure that these names should be adhered to, and the approved varieties could be grown every year against new challengers. There are various difficulties, but they can all be got over, and I hope to take active steps to institute reform during the ensuing winter. One of the points that arises is that touched upon by Mr. Chapman, viz. with regard to differences, real or imagined, in varieties that to the American eye, and perhaps the casual English eye, look alike, as instanced by Evelyn Hemus and Mrs. C. W. Breadmore. The former would, no doubt, retain the name, having been shown first and given two awards of merit, while anyone having anything that he considered superior to it could describe it as Evelyn Hemus (Smith's or Jones's stock). This would reduce the list for the public, and at the same time enable the seedsman to take credit for his efforts. It can never be possible for any committee to decide between two stocks down to the last decimal point; nor do I think it necessary. For instance, one difference between Evelyn Hemus and Mrs. C. W.

Breadmore is that the former does not grow coarse, as the latter does. If, nevertheless, it were decided by an independent body that all cream terra-cotta peepers should be known as Mrs. C. W. Breadmore, I should willingly acquiesce.—HILDA HEMUS.

Mazus rugosus.—With reference to *Mazus rugosus*, for which we were granted an award of merit at the Royal Horticultural Society's meeting on March 1, and which was illustrated on page 130 of THE GARDEN for March 15, we send you the following particulars, as there appears to be some doubt existing as to whether it is a perennial. The plant originally came from the Himalayas, and spreads by means of procumbent stems, which root as they grow. These produce flowers 1 inch in height. The fact that each rooted stem had a flower when exhibited seems to have given the impression that it was a pan of seedlings. When established it literally covers itself with flowers during the early spring months, and also produces a few solitary flowers during the summer, which are of a deep mauve colour, freely spotted orange on a white ground. The plant is undoubtedly perennial. Johnson's "Gardening Dictionary," 1868, describes both *M. rugosus* and *M. Pumilio* as hardy annuals, but there can be no doubt that this is erroneous. *M. Pumilio* is quite a distinct plant. It produces slender underground rhizomes, and the leaves are spatulate, with slightly-waved edges, which are about an inch long. It only produces its flowers during the summer months, whereas *M. rugosus*, as we have before stated, flowers during the early spring and summer months. We are not quite sure about the date of introduction.—THE WARGRAVE PLANT FARM, LIMITED.

Root-Pruning by Dynamite.—I witnessed an interesting experiment recently which should be of value to fruit-growers. Mr. Robert Holmes of Tuckwood Farm, Norwich, has a batch of healthy, young Apple trees growing upon his strong, loamy soil, but they are growing too luxuriantly and do not fruit owing to their excessive root action. For a long time horticulturists in Australia and Canada and the keen growers of the United States have sought the aid of dynamite in breaking up subsoil for such purposes as planting trees, also for further increasing the fertility of the soil, and in some cases had found the value of this agency for lifting the trees for root-pruning purposes. Mr. Holmes, ever on the alert for something new in the horticultural world, had come across this method and decided to become proficient in the use of the explosive. On the occasion referred to, thirty-two trees were lifted bodily. It may seem rough treatment to the trees, but where a large number have to be done, time and labour count for much, and, furthermore, observations have proved that the plan answers just as well as the methodical way of digging round and cutting under the tree. The method adopted is to bore with a stout crowbar a hole about fifteen inches from the trunk to a point about two feet six inches deep, in a slanting direction, to about the centre of the tree. A cartridge with a long fuse is then inserted, and the hole filled up and rammed hard. A light is then applied, and the operator has ample time to move away, just a few feet being sufficient. At the explosion there is an upheaval of the soil, and the thick roots are torn asunder. It is then the work of a very few minutes to adjust the soil and make it firm again. One could see that the force of the explosion descended as well as ascended. The whole operation of lifting thirty-two trees took less than an hour.—AVICHO PEAS.

A Useful Greenhouse Plant.—Among stove and greenhouse berried plants, *Callicarpa purpurea* occupies a foremost place, the berries being numerous and bright, glossy, deep violet in colour. It is usual to cut the old plants back in spring and start them into growth, and when the young shoots are 1 inch or 2 inches long they may be taken off as cuttings, but only those with short joints ought to be chosen. When rooted, pot off in 2½-inch pots, using the usual compost, and placing them in a temperature of 65° Fahr. Pinching back the shoots must be practised till August and all flower-buds removed. Good fruiting specimens may be obtained from pots 6 inches and 7 inches in diameter, and they must not suffer from lack of moisture, or red spider will appear. Plenty of light and air is essential, particularly after they are permitted to flower, and during this stage an occasional shake of each plant will help to secure a good crop of berries.—S

A Beautiful Early Crocus (*C. biflorus*).—This Crocus, frequently flowering towards the end of January, is a charming harbinger of spring, sending up its beautiful silvery white cups from between the very narrow, conspicuously striped and somewhat lax leaves. The buds as they rise are slender and graceful, while the rich feathering on the outside of the petals (appearing at first glance to be dark brown) proves upon close examination to be rich purple, which colouring sometimes tips the petals also. The central zone of the flower is rich yellow, as are the three stamens, while the stigmata, as in so many species of Crocus, are of an intense shade of orange. Frequently the petals are semi-transparent, so that the dark feathering shows through them when, under the influence of a sunny day, the flowers open wide. The corms appear to thrive in sandy, fibrous loam, though I generally add a little leaf-mould and grit to keep it open, my soil being rather heavy. As the corms are cheap—merely 7d. per dozen—there is no reason why they should not be extensively employed in the rock garden, where the flowers give a delightful touch of brightness during the dull winter days.—REGINALD A. MALBY.

ROCK AND WATER GARDEN.

ANNUALS FOR THE ROCK GARDEN.

A ROCK garden or rock path is a charming sight when well furnished, providing rock or stone of suitable colour is used and the permanent subjects planted to cover it are carefully chosen and rightly placed. However, as it is some time before the plants will cover their allotted spaces, during the first year or two one must have recourse to quicker-growing subjects. There are so many annuals now, both dwarf and tall, which may be used that they are indispensable, and I am sure, when once seen, will be looked for again. Many may be sown in the open, others are

and there is now plenty of variety. The dwarf forms may be planted in masses of one colour, and should be given a bold position, when their beauty will be much enhanced. The intermediate varieties, which grow about eighteen inches high, may be used in the same way. The *Antirrhinum* is not particular as to soil, therefore may be planted where more fastidious plants in this respect would fail.

Annual Larkspurs and Pinks.—*Delphinium Blue Butterfly* is very pretty, and should be sown early to obtain the best results. This should be given good soil in a position where it will not get too dry, and it will then present its true character. It is one of the best blue-flowered annuals we have, and will flower over a long period. Then come *Dianthus chinensis*, or Indian Pinks, which are

AN EARLY SPRING CROCUS (*C. BIFLORUS*) IN A GARDEN NEAR LONDON.

FORTHCOMING EVENTS.

April 1.—Royal Horticultural Society's Meeting and Exhibition at Vincent Square, Westminster. Lecture at 3 p.m. by Mr. Arthur W. Paul on "The Literature of the Rose." Horticultural Club's Meeting. Scottish Horticultural Association's Meeting. National Amateur Gardeners' Association's Meeting.

April 2.—Royal Horticultural Society's General Examination in Horticulture. North of England Horticultural Society's Show at Liverpool (two days).

April 3.—Linnean Society's Meeting. Huntingdonshire Daffodil and Spring Flower Show.

April 4.—Kingsbridge Daffodil and Spring Flower Show.

April 5.—Société Française d'Horticulture de Londres Meeting. New York International Flower Show (eight days).

best sown under glass and afterwards transplanted, and of these latter I will give a selection. There are, first, the *Ageratum*s of soft blue, lavender and white, ranging in height from 4 inches to 18 inches; *Abronia umbellata* (the Sand Verbena), rosy pink and of trailing habit. Then comes the annual *Alyssum*, Snow Carpet or procrembs, which should be planted in good masses to produce the best effect. Seed of this may also be sown where the plants are to bloom. The individual plants spread out very quickly and remain in bloom a long while. The flowers are very minute, but produced in the greatest profusion. To go from white to scarlet, there is *Alonsoa Warscewiczii compacta*, which is the best. Planted in soil that is not too rich, it will not grow too tall and will flower more freely.

The Useful Snapdragon.—The next we come to are the *Antirrhinum*s of the dwarf and intermediate sections. Though not true annuals, they are usually treated as such. They have been much improved as regards colour and form of late years,

really biennials, but if sown early and treated as annuals, make lovely pieces of colour. *Salmon Queen*, *The Bride*, *Jaciniatus*, *Queen of Holland* and *Eastern Queen* are all good varieties of different heights. The *Nemesia* is quite at home in the rock garden. It enjoys plenty of sun, and its roots should be kept moist and allowed good soil to grow in. The flowers are of all shades of yellow, red, cream pink, and white, and seen under strong sunlight are most gorgeous. There are now some new hybrids of a lovely pale blue, and another of pale lemon colour. These are dwarf in growth, and I should say would be very useful.

Another beautiful little plant is *Phacelia campanularia*, of a lovely deep blue. The flower is something like a blue *Gentian*, both in colour and form, and produces a striking effect, however planted. The foliage also turns a pretty shade with age. The next on my list is the *Portulaca*, a half-hardy annual especially suited for rockwork gardens, and one that will thrive in a dry, sunny position, where it will be seen at its best. It

quickly covers the ground, grows about six inches high, and the colours are various shades of orange and yellow.

The *Silenes* are very pretty, and should be sown in the summer and transplanted to bloom in the spring. They are very dwarf, seldom reaching more than 6 inches high, and prefer soil not too rich and an open position. Empress of India has crimson flowers and flower-stalks. Snow King and pendula alba are two good whites, and pendula compacta and Double Pink are two first-rate pinks. The latter is a very showy plant.

Although *Statice*s, the next on my list, are mostly perennials, there is one exception, *Statice Suworowi*,

The *Candytufts*, which are so free-flowering and sweet-scented. There is the White Spiral, which grows about a foot high, and also lilac, purple, carmine, crimson and cardinal, which are some-what dwarfer. All are very beautiful, and should be sown in good-sized patches of one colour. Pick the faded flowers off, and stir the soil occasionally to promote new growth.

Dianthus aurantiaca is a decided acquisition. The colour is a rich orange, with a black disc, and the flowers are little affected by the weather, although the plant is at its best when warm and sunny, and the flowers also open better. The various coloured hybrids should also be included. Another

attractive plant when in bloom. The colours are very pleasing and dainty. *Insignis* is a Cambridge blue; *l. alba*, white; *maculata*, white, with purple blotch; and *atrocærulea*, bright blue, with small spots. They all grow from 3 inches to 6 inches high and are very hardy. Two or three sowings at intervals should be made, as the plants do not last so long as some annuals. They may also be sown in autumn to bloom the following spring. *Saponaria calabrica* is an annual of rose colour, and there is also a white form. Both are old favourites with many. They are both very dwarf, and may be used in the front portion of the rockery. I conclude my list with the Swan River Daisy (*Brachycome*), a flower very much like a small *Cineraria stellata*. From a mixed packet of seed one may get many shades, or they may be purchased in separate colours. It should have fairly good soil, and be well watered if the weather is dry. The foliage is very light and pretty, and the plants grow about a foot or even less in height. It remains in bloom a long while and, though last, is certainly not the least of those I have mentioned. There are many more that I could name, but those I have mentioned will be found very useful and add greatly to the beauty of the rock garden.

R. W. THATCHER.

The Gardens, East Carlton Park, Market Harborough.

THE SHAGGY PASQUE FLOWER

(*ANEMONE VERNALIS*.)

OF the many members of this lovely family, none appeals to me so forcibly as *A. vernalis*, the Shaggy Pasque-flower. As the snow recedes from the highest alpine pastures, leaving the ground sodden and black with the previous season's decaying foliage, there rises from a few prostrate, deeply-divided leaves a beautiful bud covered with brown silky fur. When this opens there emerges a dainty, somewhat *Crocus*-like, *Anemone* flower, white or pale pink in colour, flushed with amethyst, supported on a shaggy stem rarely more than 1 inch or 1½ inches high. After pollination the petals and calyx again close over the vital organs, and, the stem elongating, allows the embryo fruit to assume a pendent habit. In our gardens this dainty Windflower has rather a bad reputation, since (as it is one of the first to open its blossoms in the mountains—frequently being in full flower within a few feet of the receding snow) it is very apt to attempt to throw up its blossoms during one of the many mild or soft intervals which characterise our winters, when, of course, it promptly mildews off, not infrequently infecting the whole plant. I have found that it grows very satisfactorily in my moraine. This *Anemone* is easily raised from seed, and I now have several plants showing flower-buds, the seed of which was sown in February, 1911, a satisfactory result when we consider that many *Anemones* take several years to come to maturity.

REGINALD A. MALBY.

THE EDELWEISS.

(*LEONTOPodium ALPIMUM*.)

THIS very popular alpine may be grown satisfactorily in a lowland garden, providing that congenial surroundings can be found for it. In the first place it is necessary to find a suitable niche in the rock garden—the position should be exposed, for anything in the nature of heavy shade from trees is very harmful to the Edelweiss. The soil should be of an open sandy nature, for a heavy adhesive soil, where moisture is likely to collect, would only be followed by disastrous results.

THE SHAGGY PASQUE-FLOWER (*ANEMONE VERNALIS*) IN A SOUTH WOODFORD GARDEN.

a plant of singular appearance. The foliage looks something like a Dandelion leaf, and the flower-spikes are thrown up from the centre. The colour is rosy pink, and the individual blossoms are very minute, packed closely together on stalks about eighteen inches high.

Sowing and Thinning.—I will now name some that may be sown where they are to bloom, and with proper attention to sowing, thinning and keeping clean will produce equally as good results as those that are raised under glass and planted out. The great thing with all annuals is to thin them out sufficiently, according to the kind, and give them every encouragement afterwards. I first mention the Pimpernel, or *Anagallis*, to give it its proper name. There are two colours, pale blue with a black blotch in the throat, and a brick red shade with the same markings. They remain in bloom a long time, especially if the faded blooms are kept picked off. They should be given a warm, sunny position, or the flowers do not open well.

Another effective plant is *Cacalia cœcinea*, the Tassel Flower. This grows about a foot in height, and has flowers like a double Daisy on slender stems. The foliage is very luxuriant and of a nice green shade. It is a plant that is always noticed by reason of its very bright colour. Then come

pretty plant is *Ionopsidium acule*, the Violet Cross, a tiny thing covered with little lilac-coloured blossoms. It is admirable for sowing in narrow crevices between the stones, and should be kept moist at the root, or it is apt to shrivel up. It does not grow more than 2 inches high, and does not spread like many dwarf plants. Then come the *Linarias* or Toadflax, indispensable little plants. *Aurea reticulata* is crimson and gold, and *bipartita splendens* is purple and light blue. Both grow about a foot high, and should be sown thinly and not thinned out too much, as they are very slender in growth. The blooms are very small and something like a miniature *Antirrhinum*. I consider them among the prettiest of our dwarf annuals. *Lunaria grandiflorum rubrum* is a dark shade of red, as the name suggests, and is very nice in contrast with some of the lighter-coloured flowers. Then the

Dwarf Nasturtium deserves a place, and is another plant that flowers better in soil that is not too rich, and also in a dry season. Two or three sowings should be made to prolong the season. The flowers are all shades of yellow, crimson, scarlet and rose, and some are spotted and veined with deeper markings. Some have golden foliage and others are silver variegated, which produce a fine effect even if they never flower. The next that claims attention is the *Nemophila*, a most

THE GREENHOUSE. THE FLOWER GARDEN.

CARDINAL'S FLOWERS.

A CHARMING COOL GREENHOUSE PLANT.

(CALCEOLARIA ALBA)

ALTHOUGH discovered in Chile so long ago as 1844, this pretty plant is seldom met with in our gardens. I must confess to never having seen it until a year or two ago, when an amateur friend gave me a few cuttings to root for him. This I did; but when my friend discovered that this Calceolaria required greenhouse treatment he had no use for it, so I secured the lot, and a really handsome and useful plant it has proved. Like all Calceolarias, it requires very little artificial heat; indeed, the cooler it is kept the better it appears to thrive. After the cuttings are well rooted they should be pinched to induce a bushy growth and be grown steadily on. A compost of good turfy loam, leaf-mould and sand suits them admirably; but the addition of a little well-rotted manure and bone-meal is an improvement. The flowering pots need not be larger than the 6-inch size. Moderately firm potting seems desirable. After the pots are well filled with roots, an occasional soaking of weak liquid manure, or lithemic Guano in water, is very beneficial. Slender stakes about eighteen inches long must be provided in good time, and the shoots lightly tied to these. Like all the members of the family, this variety is very liable to be attacked by green fly. It is well, therefore, to vaporise occasionally to keep these pests in check.

Coming into bloom in July, the plants continue in full beauty for three months at least, and even on November 23 last there were a few nice blooms left. It is a plant that claims attention at once, as it is so unlike any of the other inhabitants of the cool greenhouse. Every visitor here last summer was interested in it, and not one knew what it was. The foliage is light and graceful, and not at all like any of the herbaceous or shrubby kinds usually cultivated in our gardens. When out of flower, several people have mistaken this Calceolaria for the perennial *Alonsoa*. The foliage is, indeed, very similar in size and shape, but the Calceolaria when touched has the sticky feeling of *Diplacus glutinosus*. The flowers are pure white, small in size and borne in graceful sprays on wire-like stems. They are excellent for cutting, and altogether it is a very desirable plant. C. BLAIR
Preston House Gardens, Lullithgow.

ASPARAGUS SPRENGERI.

If seedlings are transferred at an early stage to 4-inch pots, it is surprising what nice little bushy plants they make before any very long shoots are formed. We have seen these used very effectively for corners of dinner-tables and on small tables in drawing-rooms. They remain a considerable time in this small state, and, being easily raised, seed may from time to time be sown to provide succession.

PRICKLY PEARS IN THE OPEN AT CAMBRIDGE.

NOT the least interesting feature of the famous Botanic Gardens at Cambridge is the large colony of Prickly Pears, or Opuntias, that for years have been established in a sunny position near to the range of glass-houses. *Opuntia robusta*, a particularly well-named species, seen in the foreground of the accompanying illustration, has so far grown beyond bounds that it would be an extremely difficult task to enter by the greenhouse door, even if one wished to do so. The flat, more or less circular branches, studded with spines, are from 1 foot to 1½ feet across. The plants are literally growing wild, and just revel in their warm, sunny position outdoors. The less formidable but equally rampant Prickly Pear spreading over a wide area in the background of the picture is *O. cantabridgensis*, the origin of which is unknown. There are many and diverse forms of *Opuntia* in this collection, and among others might be mentioned *O. arborescens*,

but all perennial *Lobelias* have much of interest in their history, and a certain degree of mystery attaches to the varieties at present cultivated by hybridists having so mixed the progeny of species that it is impossible to unravel their pedigrees. Those which I cultivate were selected from seedlings of many colours, the deep crimson ones alone being retained. So early as 1621 *Lobelia cardinalis* was cultivated in England, the stock having arrived *via* France from Canada. It was then known as "*Trachelium americanum flore ruberrima sive Planta Cardinalis, the rich crimson Cardinal's Flower*." In 1695, Rea incidentally mentions the introduction of *L. siphilitica* in these words: "There is another of this kind (which lately came from Virginia) with blew flowers"; and it is worth while noting that the early authorities called the plant "*Cardinal's Flower*" and not *Cardinal Flower*, as we do to-day. Valuable additions were obtained in *L. fulgens* in 1809 and *L. ignea* in 1838 (see Paxton's "*Magazine of Botany*," Vol. VI.), the flowers of this being blood red and the leaves coloured. A writer in Harrison's "*Floricultural Cabinet*," in which the flower is also portrayed, recommends the stems to be stopped to induce

PRICKLY PEARS OR OPUNTIAS GROWING OUTDOORS AT THE CAMBRIDGE BOTANIC GARDENS.

a native of Mexico, said to attain a height of 20 feet to 30 feet at its southern limits, but so far of dwarf dimensions at Cambridge; and *O. monacantha*, the One-spined Prickly Pear, a native of Brazil.

It might be mentioned that the illustration was prepared from a photograph taken only a few days ago, the plants having wintered in the open. The economic uses of *Opuntias* are varied. The fruits, known either as Prickly Pears or Indian Figs, are edible. Some species are grown in warmer climes as food for the cochineal, while others are appropriately used for hedge-making.

a bushy habit, which might do for pot culture, but would inevitably retard the production of bloom out of doors. The name *Lobelia*, it may be added, was bestowed upon a stove shrub now called *Scavola Plummeri*, by Father Plummer, which was introduced by Catesby in 1724. Though one of the most glorious of all autumnal flowers, it is seldom seen at its best, and in the majority of gardens one visits it is never seen at all. It is too true that it is sometimes a difficult plant to preserve over the winter, a fact recognised by Rea, who gives very good instructions for its preservation. But by consistent attention to a few details, losses

may be reduced to a point not worth taking account of. Warmth is inimical to the plant in winter, for, though not hardy enough to stand every winter unharmed in the open, it is at least sufficiently hardy to be preserved in a cold frame. The plan I have practised for many years is to lift each plant with a ball of soil, packing the plants close together in 4-inch-deep cutting-boxes, which are afterwards arranged in frames and deeply covered with dry, flaky leaf-soil. In very frosty weather a further covering of dry straw above the leaf-soil is sufficient to enable them to withstand the winter.

Propagation is effected by division in spring, when the boxes are transferred to one of the plant-houses, the bulk of the leaf-soil removed, and the plant, for the first time since being lifted, watered, and afterwards given moisture as required. Division does not take place till growth is well advanced, when each piece contains three or four growths, and is replanted in an open rich compost in other boxes, in a week or so being again transferred to cold frames, and finally planted about the end of April. A highly manured soil, with summer mulchings, is essential to success. Equally important is the way the plants are arranged, which should always be in masses. Single-stemmed pieces planted widely apart can afford no good idea of the decorative value of the plants; therefore, when grouped by themselves, they should almost touch each other. That is the way I use them in mixed borders. But for the best decorative effects they must be arranged in large beds or borders with other suitable plants. In the present year I shall use about 1,500 plants in large oblong beds, mixed with *Centaurea Cyanus* to a width of about 6 feet, with *Tritomas* and blue Stock-flowered Larkspurs behind. Last year, in an arrangement that gave much satisfaction, the *Lobelias* were thickly dotted as an under-ground to heavy masses of the same Larkspurs in batches of five, which formed pillars 7 feet in height. A few tall yellow *Antirrhinums* were also introduced, with a dwarf mauve *Ageratum* filling any odd vacancies. Where many cut flowers are a necessity, a portion of the stock should be grown for the purpose of providing material to cut. The flower-spikes cannot be surpassed for richness of colouring, and few things last better. Very brilliant flowers for table decorations have been condemned, but not everybody disapproves of strong colours, and for this purpose, too, the flowers are greatly valued. In fact, there are a great many uses to which these brilliantly-coloured flowers may be put, both in a growing and a cut state, and it is difficult to understand why they are not more extensively grown. They are well worth taking some pains over, and are sure to be highly appreciated if grown to anything like perfection.

Prestonkirk, N.B.

R. P. BROTHERSTON

A JULY BORDER.

THE portion of flower border shown in the accompanying illustration is in the garden of Mr. Walter Jesper, Beechwood, Menston-in-Wharfedale, Yorkshire, who kindly sent us the photograph and the following notes: "The photograph was taken when the border was at its height of beauty, i.e., about the second week in July. The flowers just showing at the bottom right-hand corner are *Campanulas*. High above them is the splendid *Delphinium Reynaldo*. Between this and the *Cupressus* is the beautiful creamy *Delphinium Beauty of Langport*, which shows to great advantage against the dark foliage behind. Just below is a young plant of *D. Belladonna*, in front of which

A MIXED BORDER IN A YORKSHIRE GARDEN, FROM A PHOTOGRAPH TAKEN IN JULY.

rise the handsome, tall leaves of *Iris Monnieri*, not yet in bloom. Below this is a spike of the white Mallow, while on the stone edging are *Saxifrage* and the charming little *Campanulas pusilla* and *pusilla alba*. In the centre of the picture, just to the left of *Delphinium Beauty of Langport*, are the graceful spikes of *Anchusa italica Opal*. Beyond is an old-established plant of the early-flowering white *Phlox*, and near the edge of the border is a group of *Veronica spicata alba*. Further groups of *Delphiniums* are seen in the background. Altogether, the effect of this long border (some 12 feet wide) in what we call our 'blue fortnights' in July is one that lingers long in the memory, even when winter is upon us."

AN INTERESTING EASTER FLOWER.

(*FRITILLARIA MELEAGRIS*.)

FRITILLARIA MELEAGRIS, commonly known as the Snake's-head *Fritillary*, is one of the gems among British plants. There are a few places in England where it may be seen growing freely, particularly in the meadows round Oxford, where children gather the flowers in large bunches as a rule about Eastertide. It also occurs among the rich limestone pastures of North Wilts, where the flowers are called *Toads'-heads* by the natives. Near to the village of Oaksey are two or three meadows, where it can be seen in magnificent profusion. Concerning *Fritillaria Meleagris* in this particular neighbourhood, it is a source of wonder to the natives that the colony is on the march, ever moving, though but slowly, in an easterly direction. A most interesting article on this subject by a correspondent, "F. J. F.," appeared in *THE GARDEN*, July 29, 1911, from which we take the following: "As regards the gradual eastward march, I have a very respected relative who has lived continuously in that village the whole of her life, something over ninety years. Within her memory the *Fritillarias* have moved across several fields. I cannot help thinking that three or four centuries ago the original stock was planted in the gardens attached to Malmesbury Abbey, fostered there by those monks to whom we owe the preservation of so much. As in course of time the Abbey, with its gardens, fell into decay, so these flowers, in accordance with the direction of the wind at the time the seeds were ripened, sowed themselves on their eastern front, while the old bulbs on the western rear gradually died out. My theory may be wrong, but it is very feasible, and certainly is able to account for this isolated colony of a very rare and very beautiful native flower."

There are many beautiful varieties of this subtle flower, one of the finest being that named *Emperor*, illustrated on page 159. There is a belief among country folk that no one can successfully transplant the *Snake's-head*; but this, no doubt, is the result of lifting when in flower, which would, naturally, end in disastrous results. The bulbs may be removed with impunity in August, and will thrive in the border or the rock garden if given congenial soil.

As pot plants, with several bulbs in a pot, the varieties of *F. Meleagris* are exceedingly dainty. Moreover, they may be grown in bowls filled with fibre, in much the same way as *Hyacinths*, *Daffodils*, *Tulips*, or *Crocuses*, that are now so extensively grown as room plants. We have quite recently seen some excellent bowls of *Snake's-heads*, but the bulbs require very careful treatment when grown in this manner.

ROSE OLD GOLD.

COLOURED PLATE. THE ROSE GARDEN.

PLATE 1468.

ROSE OLD GOLD.

THE wonderful colours, or blendings of colours, we are getting in our modern Roses were certainly never dreamed of by Rose-growers of years ago. In the *Florist* of October, 1855, the late Thomas Rivers wrote: "One almost fears the point of perfection has been attained, and that no better Roses than those we now possess can, or will, be originated." Whether Mr. Rivers referred to form, colour, or vigour one does not know, but surely all three attributes have been vastly improved since those days. Even as far back as twenty years one would not have ventured to prophesy that we should be having such colours as raisers are now giving us. Certainly one of the most delightful will be the Hybrid Tea Old Gold, the splendid production of Messrs. S. McGredy and Son. As I saw it at Portadown last July it was truly marvellous, and I was not surprised to find that this variety secured for the lady decorator the first prize for a table display. It was thought, when the same raisers gave us Mrs. Alfred Tate, that they had scored a triumph, and now we have Old Gold, which seems to be a replica of Mrs. Alfred Tate in all save colour; in fact, I think I am right in saying that the latter Rose was one of its parents. That it will be a popular garden Rose is already assured, and I predict for it a great success.

Where these raisers are obtaining these glorious shades is a mystery. Of course, they have, as all raisers have, their own "bloods," and I fancy they have still more wonders in store, for I question if there has ever been seen a house of Rose seed to equal that at Portadown last year. Fancy one house 90 feet long containing plants carrying some 7,000 cross-fertilised pods of seed. Upon one plant alone I saw some 300 pods, all tallied, and this plant, a seedling, had already produced Roses for its owners that had gained four or five gold medals. This firm has some of the most glorious canary yellows I have ever seen. One or two especially took my fancy, for the flowers were produced on stems as rigid as a Mrs. Theodore Roosevelt, and all who have much to do with bedding Roses know what a valuable trait this is in a Rose. I only hope Messrs. McGredy will not keep us waiting long for them, and I almost wish they would send out a dozen novelties every year, although our collection now is so embarrassing, I am not one of those who bemoan the influx of novelties, providing they are really good and an advance upon existing sorts. By all means let us encourage them in every way we can. Some old-fashioned florists may repudiate these newer artistic Roses and say they are wanting in form and substance; but I know which are most popular with the general public, and these are the decorative kinds, of which Old Gold is a beautiful example.

DANECROFT.

THE PRUNING OF ROSES.

(Continued from page 144.)

HYBRID PERPETUALS

HYBRID PERPETUALS are generally nice, easy subjects to prune, and it is perhaps possible to grasp the general principles of pruning dwarf plants more readily with them than with most other groups of Roses. It is, therefore, worth while to consider their pruning rather carefully. It should be taken in hand during March, and in the writer's opinion the earlier in that month the better, and even the end of February may often be convenient if there are many to get through; but this view is not accepted by all rosarians. However this be for reasons which will appear later, the earlier in the year we prune these Roses, the harder they may safely be

buds at the top of the pruned stem will grow out and produce flowers, and, besides this, sometimes in the first growing period, but more often during the second period, the third, fourth and occasionally the fifth bud from the top will break and form shoots; but the lower buds and the invisible or dormant buds at the base of the plant will not grow either in the first or second growing period. This effect and mode of growth may be traced in the left-hand branch of the plant shown in the illustration (Fig. 1) of a Hybrid Perpetual before pruning. This method of pruning may often be noticed in old-fashioned gardens. Its disadvantages are, first, that it does not allow of the replacing of the old wood, basal shoots being seldom produced; and, secondly, the growing and flowering parts of the plant in a course of years gradually rise further and further from the roots. Turning now to the opposite extreme, when the pruning has been too severe, we may perhaps

A BEAUTIFUL SNAKE'S-HEAD FRITILLARY, FRITILLARIA MELEAGRIS EMPEROR.

cut back. Whether we desire our flowers for exhibition or for our own enjoyment in the garden, there should not be any very great difference in our treatment of the plants, for in the case of Hybrid Perpetuals the object in view will, in both cases, be the production of well-shaped specimen flowers. The difference in treatment between these Roses when grown for exhibition flowers and for the garden will generally occur later on, when the thinning out of the superfluous shoots takes place in May. The best course to pursue in pruning will be most simply shown if we consider first the effect of pruning these Roses too little, and then of pruning them too severely.

As is well known, the Hybrid Perpetuals have two flowering periods in each year, each flowering being preceded by a period of growth, the first taking place in spring and early summer, the second, in late summer, ultimately carrying the autumn flowers. The effect of leaving the stems too long at pruning-time will generally be that one or two

find a single shoot only starting from the cut-back shoot of the previous year, and, this being insufficient to absorb the sap sent up by the roots, the dormant buds at the base of the plant are forced into premature growth and push up strong, sappy, basal shoots, called by the Americans "watershoots" and by the French "gourmands." They usually occur on the same side of the stem as that on which the bud was originally inserted, and absorb the energy of the plant, to the detriment of the higher and more useful branches.

It is probable that in most cases the best flowers are obtained when only two of the buds on the young stems of the previous year are allowed to develop in the first or summer growth, and they should be as near to its base as practicable; but the cutting back should not be sufficiently severe to induce the dormant buds in the collar of the plant to take part in this first growth. These basal shoots, however, will generally develop in the course of the second or autumnal growth.

It is true the autumn flowers on these particular basal growths may often be poor, but they will not be the only flowers, and if the stems have been formed early enough to ripen well, they may be retained and utilised for the production of the flowering shoots of the following spring, the old and now branched stem which had produced flowering shoots the previous summer being cut right away. But it is often well to retain one or two of the best of these old stems.

By following this method we practically work each stem on a two years' system, and the renewal of the young wood becomes continuous. We may now see why it is that the later in the season pruning is deferred, the more buds should be left on the stems, and, conversely, the earlier we prune, the harder it is safe to cut back. Although the great bulk of the food supply comes from the leaves, yet early in the year, before these have developed, the material for the formation of the early growth must of necessity come from the reserve material stored in the roots and carried up by the rising sap. Early in the season the flow of sap and reserve material is not great, and if the plant be then pruned hard back, though only a few visible buds are left, yet these will slowly develop without starting the dormant buds in the first growing period. Not so, however, if the same course be pursued later on in the season, when the flow of sap and reserve material is in full swing.

The system indicated above may seem simple enough to read of, and so it is in practice with free-growing Hybrid Perpetuals which readily make ripened shoots in their second growth; but they do not all do this, particularly the weaker-

growing varieties, such as Duchess of Bedford and Prince Arthur. Some of these plants will often fail to push up any young basal shoots at all, or such shoots as are produced in this way may be sappy, unripe and quite unreliable. What is the pruner to do then? Dogberry charged his watch to bid any man stand in the Prince's name. "How it a' will not stand?" said the watch. "Why, then," answered Dogberry, "take no note of him, but let him go . . . and thank God you are rid of a knave." Many a good man before and since Dogberry, when dealing with a subject, whether animal or vegetable, which declines to act in the manner expected of it, has found no better answer than Dogberry's. Here, in fact, the pruner's art, his experience and judgment come into play. The plant may be healthy enough, but it has perhaps been neglected, and he must consider how to restore it for the production of useful new growths. It may be sufficient to prune the plant to one or two eyes of the last summer's growth, or the shoots may be left longer and partially bent or pegged down; or, again, pruning may be deferred somewhat later than is usual, so that the sudden check may induce it to break back. In the case of Roses that have been freshly planted in the previous autumn and do not seem to have come through the winter well, it is often policy to delay pruning somewhat beyond the ordinary period. Everything must be done to promote new growth, and, in particular, that from near the base of the plant, while if, when all has been done for this end that is practicable, success does not result, then take Dogberry's advice and let him go, to make way for a better plant.

In cases where strong-growing Hybrid Perpetuals, such as Frau Karl Druschki, Hugh Dickson and Commandant Felix Faure, are grown in isolated beds and the long, autumnal growths are objected to, it is sometimes advisable that the growth of the previous year should be left longer than usual, something, in fact, like the plant shown in Figs. 1 and 2, in order to check its tendency to form basal shoots; and some even go so far as to lift the bushes and replant every autumn with a similar end in view.

There are also a few Hybrid Perpetuals, mostly of recent introduction and single-flowered or nearly so, at least with rather small and numerous flowers, such as Maharajah, Comander Jules Gravereaux, Ards Rover and, if it can be included here, Gloire des Rosomanes, where the production of a large quantity of bloom is of first importance, and here, again, very little pruning is necessary; in fact, it may be confined to thinning out old shoots which have already flowered, where necessary, to give room for younger shoots to develop.

Let us now turn for a moment to the illustrations. Fig. 1 shows a rather vigorous Hybrid Perpetual before pruning, and Fig. 2 is the same plant after

2.—THE SAME BUSH AFTER PRUNING. THE PLANTS WERE LIFTED AND POTTED FOR CONVENIENCE IN PHOTOGRAPHING.

the operation has been performed. Taking the stems which remain after pruning in order from the left No. 1 is an old stem on which two shoots of the previous year have been retained. As this old stem is to be kept, one or two buds of the young shoots from it must also be retained. Next comes No. 2, a young, vigorous stem; No. 3, another old stem with two young shoots; No. 4, a vigorous young growth; and No. 5, pointing towards us, a rather less robust young shoot. For strong growers, such as Frau Karl Druschki, Duke of Edinburgh, or Hugh Dickson, this amount of pruning would be about right; but with the majority of the Hybrid Perpetuals it would be better to shorten still further. In the case of a variety rather less vigorous than those named, such as Victor Hugo, Nos. 2 and 4 should be shortened to about half the length shown, choosing, of course, an outward pointing bud for the top one retained. No. 3 might be removed altogether, and No. 5 shortened by about one-third of the length shown in Fig. 2. It would probably in any case be necessary to leave No. 1 in order to keep the plant nicely balanced, but not more than three good buds should be left on each of the two young branches.

But whichever mode of pruning is adopted, something yet remains to be done. There is the end of a stump left in the middle of the tree, and two stumps may be seen at the base. If these are left, they will only die, and perhaps lead to the introduction of disease. They must be pared right away with the pruning-knife, often an awkward job, and the wound painted over with some styptic, such as knotting or priming paint. This styptic may also be applied to the cut tips of the branches.

I have dealt with the Hybrid Perpetuals at considerable length, because the theory of the operation is more readily grasped with Roses of this class than with any others. In my next article I propose to apply this method to the Hybrid Teas, Teas and Chinas. The pruning and training of the multifloras and wichurianas should have been finished before January was out, and the rugosas are usually pruned in February, so I do not propose to deal with them at present. WHITE ROSE.

(To be continued.)

1.—A HYBRID PERPETUAL ROSE BEFORE PRUNING.

GARDENING FOR BEGINNERS.

ANNUAL FLOWERS WITH CLIMBING HABITS.

THE value of climbing annuals for quickly covering bare fences, clothing ugly corners, or hiding up any unsightly object in the garden can hardly be overrated. Speaking generally, the cultivation of climbing annuals is simplicity itself. The spring-sown seedlings grow rapidly, and beyond an occasional tie or a little care in training the shoots, very little attention is required.

Foremost among the climbing annuals must be mentioned the ever-popular Sweet Pea, but when grown with the idea of forming a screen it is advisable to select those varieties known to be strong growers and to avoid particularly those of salmon shades, such as Henry Eckford, that are not of robust habit.

Although not usually grown as an ornamental subject, the Scarlet Runner Bean forms one of the most effective annual screens that can be desired. The beautiful orange scarlet flowers are by no means appreciated as they should be, and here it might be mentioned that the colour of the Scarlet Runner flower was long sought after by raisers of new Sweet Peas.

The Morning Glory (*Convolvulus major*) is another easily-grown subject that commands admiration, especially when the flowers are seen at their best. Its uses as a climbing annual are manifold, and in the accompanying illustration it is shown clothing what would otherwise have been a bare and by no means beautiful lamp-post. For such a purpose there is nothing to excel the Morning Glory, as it is a rapid grower and attains a considerable height, while it readily entwines itself around strings arranged from the ground to the top of the lamp-post. The Morning Glory, however, is none too hardy, and seeds should not be sown before April.

One of the most popular of climbing annuals is undoubtedly the Canary Creeper (*Tropæolum canariensis*). This, again, is none too hardy, and the most satisfactory way of growing it is to sow the seeds in frames in April, afterwards transplanting the seedlings to their flowering quarters. Its harder relative, the common Nasturtium in climbing form (*Tropæolum majus*), is everyone's plant so far as cultivation goes. It should, however, be grown in a poor soil in preference to a rich one. If the soil is heavy manured, the plants will grow apace and make an overabundance of growth and green foliage; but one may look in vain for the flowers. Indeed, most annuals give better results on a poor or moderate soil, the Sweet Pea being a notable exception.

Although not an annual in the strict sense of the term, *Cobæa scandens* is grown as such in many gardens in the South. In one of the London parks the writer has often seen this handsome climber used for clothing dwarf trees or shrubs that may have died from some cause or another. By utilising a climber in this way, bare gaps in the

have come very much to the fore in recent years, and are specially suited for growing singly up stout Larch poles.

A very simple arrangement for growing climbing annuals is to fix three stakes in the ground in the form of a triangle, securely binding them together at the top to form a tripod. Such climbers as *Convolvulus* and Canary Creeper look very pleasing when grown in this way.

A LAMP-POST CLOTHED WITH ANNUAL CONVULVULUSES BY A CARRIAGE DRIVE.

shrubbery may be avoided. *Cobæa scandens* and its variegated form are most often met with as greenhouse or conservatory roof climbers, and when grown under congenial conditions the plants are of perennial duration.

Ecremocarpus scaber is another very useful climber. It is particularly suitable for arches and pillars, where its orange flowers are seen to perfection.

Neither must we omit to mention the Japanese Hop (*Humulus japonicus variegatus*), which should be sown without delay for the coming season's display. Finally, we mention the ornamental Gourds, in diverse and fantastic types. These

COLUMBINES FOR SHADY BORDERS.

AMATEURS are often unable to satisfactorily fill shady borders with flowering plants. The above-named plants are very suitable, as both the foliage and flowers come so fresh when developed in light shade. Furthermore, the plants are splendid for growing in damp borders, providing the soil is well drained. By damp borders I mean those that are low-lying, and in which moisture collects regularly in consequence. The ordinary *Aquilegia*, or Columbine as they are often called, cast their seeds, and the resultant seedlings spring up and thrive amazingly; but the rarer varieties require much more careful treatment. Instead of putting out the young seedlings in their flowering quarters among strongly-growing herbaceous subjects, they should be first transplanted in a nursery bed. First put down a layer of well-rotted manure 2 inches deep, then one of gritty soil 4 inches deep. In this bed put out the young plants 6 inches apart each way.

Early in the spring the young plants must be transferred to their permanent positions, the soil of which should be deeply dug and well enriched with road grit, leaf-soil and rotted manure if it be of rather poor quality. Plants so treated will make good specimens by the summer and bear some flowers.

If overcrowded in a herbaceous border while they are small, they rarely make good flowering plants the same year. By placing the rotted manure under the soil in the nursery bed the cultivator is enabled to lift the plants with nice balls of soil attached to the roots, so that the plants do not feel any check and continue to grow steadily. The flowering season is from June to the end of August. *Aquilegia californica*, scarlet; *A. cærulea*, violet and blue; *A. e. albiflora*, white; *A. chrysantha*, golden yellow; *A. chrysantha*, double; *A. Stuarti*, blue with white cap; *A. glandulosa*, blue with white corolla; and the many long-spurred hybrids are all very charming varieties.

G. G.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Pleasure Grounds.

Mowing.—This will now become a weekly or bi-weekly operation, according to the weather and strength of the grass; and if a good, firm, green lawn is desired, it is advisable to keep the mowing well in hand. If left for too long a time, the grass has to be gone over twice, and if the growth is thick, the bottom soon turns pale in colour, and is very easily injured by the frosts that we are still likely to get.

Feeding.—Where the growth of the grass is weak, a dressing of some approved grass manure should be applied during the next few weeks, preferably during showery weather, or, failing rain, it may have to be washed in with the hose.

Worms.—Although these are credited with being beneficial for the drainage and feeding of a lawn, the casts thrown up during mild, showery weather are anything but pleasant to see. A special effort should be made to rid tennis and croquet lawns of worms, and by far the best means of doing this is to use Carter's Worm Destroyer. This, evenly distributed and well washed in, will thoroughly clear a lawn of worms for a year, and in some cases even longer.

The Rose Garden.

Pruning.—Now that the month is drawing to a close, it will be well to complete all the Rose-pruning. After finishing the Hybrid Perpetuals, all the Hybrid Teas may be done.

Plants Under Glass.

Chrysanthemums.—The early-rooted Japanese varieties may be ready for potting on into 6-inch pots, and this should be done, before the roots become too densely matted, in 4-inch or 4½-inch pots, or the plants will sustain a check. January and February rooted plants may not require a shift just now, but any lack of attention as to watering and potting will eventually show itself in the plants, either in loss of foliage or premature hardening of the stems.

Cuttings for growing on as single-stemmed plants may be rooted now, and these, if well looked after, make excellent plants for grouping either in the conservatory or at exhibitions.

Fuchsias.—Old plants that have been pruned and placed in gentle warmth will now have made sufficient growth to warrant their being partially shaken out, or the old ball reduced and repotted into the same-sized pots. Young plants that are being grown on as specimens must be given a slight shift as often as they require it, using a fairly rich and light compost. These plants like a moderately warm, moist atmosphere while making their growth, and, according to the shape the plants are required, so they must be pinched. Pyramids are perhaps the most useful, though standards of some varieties are exceptionally pleasing in certain positions in the conservatory.

Pandanus Veitchii is one of the occupants of the stove which are much admired and very easily grown. The old plants are now throwing small suckers from the base, and if these are removed, inserted singly in small pots and placed in the propagating-frame, they will soon make roots. To maintain good variegation in the foliage, a very light and porous compost should be used, putting very firmly when placed in 4½-inch pots.

The Kitchen Garden.

Vegetables in Frames.—Peas, Broad Beans, Cauliflowers and any other vegetables raised under glass for planting out should now be given all the air possible to harden them off preparatory to planting, and though this may not be permissible for a week or two yet, the hardier they are the better will they grow away when placed in the open.

Herbs.—The herb border should now be gone over, digging up and replanting anything that requires it, splitting up such plants as Thyme, Chives and Tarragon, while small sowings may be made of Borage and Chervil.

Mint.—To keep up a supply of Mint till well into the autumn, I prefer to make a small plantation each spring, pulling up the young shoots with a piece of root attached and dibbling them in a piece of fresh ground in rows 1 foot apart and 4 inches between the plants or cuttings. By about July

such a bed will have made sufficient growth to warrant the old bed being dug up. For an early supply for forcing next season, such shoots, pricked off in boxes 3 inches apart and grown on all the summer, give a much better return than lifting the roots and placing in a frame, as a box may be placed indoors every week or ten days, according to the quantity required.

Fruits Under Glass.

Vines.—Too heavy disbudding of young shoots should be avoided, as occasionally there are losses when the shoots are being tied down, and it is easy to remove a shoot or two when it is found that the desired number are quite safe. Alicante and one or two other very strong growers are the worst sufferers in this respect, and need very careful tying.

Stopping the Shoots.—Generally speaking, the shoots should be stopped two leaves beyond the bunch; but where there is ample room between the rods, this rule need not be rigidly adhered to. In fact, where the Vines are none too strong and the foliage small, I believe it is an advantage to extend them an extra joint or two. All lateral growths should be rubbed out to the bunch, pinching those beyond the leaf at the first or second joint, according to the space at command. Overcrowding of the foliage should be avoided, as one well-developed leaf is better than two or three anæmic-looking leaves that are partially stifled for want of light and air.

Melons.—Plants that have set their fruit should be top-dressed with good loam and a little manure, which, as soon as filled with roots, may have the help of a weekly dressing of a good artificial manure. The present is a good date for sowing a batch of Melons for cultivating in frames. Although most varieties will do well in frames with good treatment, the smaller varieties, such as Hero of Lockinge and Blenheim Orange, are, I think, the most suitable. Cantaloupe Melons may also be sown, and such plants would be ready for placing in the warm frames at about the time the bedding plants are being removed to the cold frames for hardening off.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Adlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Bedding Geraniums.—Although not so popular as they once were, these showy bedders have still many admirers, especially that glowing scarlet variety Paul Crampel. The plants should now be transferred to cold frames to be gradually hardened off. Keep rather close and dry for the first ten days, and then inure them to the air by degrees, according to the weather.

Calceolarias.—If frame room is scarce, these may be run out in trenches similar to Celery trenches. Lay a few rods across the trenches to support mats in the event of frost occurring.

Half-Hardy Annuals.—As soon as these show the first pair of rough leaves, they should be pricked off into boxes filled with equal parts of loam and leaf-mould with a little sand in it. When sowing this compost, place the rough part in the bottom of the boxes to encourage root action.

Hardy Annuals.—These may be sown within the next fortnight. Such things as Nigellas, Poppies, Candytufts and Eschscholtzias may be sown where they are to bloom; but with many of the finer varieties it is worth while to sow them in cold frames or under improvised protection formed of rough boards and sheets of glass in some sheltered, sunny nook. This precaution is chiefly taken to protect the tiny seedlings from slugs and snails.

Herbaceous Plants.—All bulbous plants will now be pushing, and the work of forking over the beds and borders may be proceeded with. If previous hints were acted upon, all top-dressing will have been attended to; this, however, is a good time to give dressings of soot or ground lime. Any necessary planting or reduction of the plants should now have attention. In carrying out the latter operation, retain a portion near the outside of the clump, where it will be observed the pushing growths are stronger than in the centre.

The Rose Garden.

Pruning Teas.—With the later additions to the Hybrid Teas the difference between them and the Teas is almost indistinguishable, whether as regards colour, form, or constitution. Taking the Teas as a class, however, they should be pruned harder than either the Hybrid Perpetuals or the Hybrid Teas; but in carrying out the work of pruning the same general principle as that laid down here a fortnight ago must be observed, viz., the weaker the variety, the more closely should it be pruned. Except in very cold localities, the work of pruning may now be proceeded with.

Plants Under Glass.

Zonal Pelargoniums.—The cuttings inserted a few weeks ago to furnish plants for late autumn flowering will now be ready for potting up into 3½-inch pots. Use a compost of two parts loam to one part good leaf-mould, with a little sand. Keep the plants in an intermediate temperature for another week or two.

Tuberous Begonias.—Tubers started a month ago should now be ready for potting off. The size of the pot must be determined by the size of the tuber, but do not give too much room at first. Equal parts of fibrous loam and half-decayed Beech leaves passed through a three-quarter-inch mesh sieve, plus a little sand and pounded charcoal, will suit them at this stage. Barely cover the tubers and pot lightly. Shade from bright sunshine and do not coddle.

Fruits Under Glass.

Thinning Grapes.—This delicate and important operation should be carried out with great care, more especially if there is any thought of exhibiting. The Muscat varieties and those of the Hamburgh type require somewhat different treatment, although certain general principles apply to both. These principles are as follows: Never reduce the circumference of the bunch; maintain its symmetry as far as possible, aim at leaving the berries a uniform distance apart, and cut out the small berries as far as is consistent with this. Muscats, having stiffer and shorter footstalks, must be more severely thinned than Hamburghs.

Strawberries.—As the fruits begin to ripen, give them the benefit of all the available sunshine, also a little air on all favourable occasions. Continue to give mild stimulants to plants whose fruits are swelling.

The Hardy Fruit Garden.

Protection from Frost.—As fruit trees on walls come into flower, a close watch should be kept, and they must be protected from frost by means of netting. It is wonderful what an amount of protection is afforded even by a single net, and a double net will ward off all but an abnormally sharp snap of spring frost.

Raspberries.—As soon as the young growths are 6 inches high, all surplus ones should be cut out, as they only tend to rob the others of their due share of light and nutriment. Six canes is the maximum number that should be allowed to a stool.

The Vegetable Garden.

Vegetable Marrows.—Seeds of this useful vegetable should now be sown in a little heat in 4-inch pots, one seed to a pot. Moore's Cream and Long White are two excellent varieties, the latter being a heavy cropper.

Cauliflower.—Autumn-sown plants may now be planted out on a south border in well-prepared and highly-enriched soil. Lift carefully and plant with a trowel. Place a ring of soot round each plant to ward off the attacks of slugs. Plants resulting from an early sowing under glass should be pricked out under frames or hand-lights and gradually hardened off.

Staking and Sowing Peas.—The early sowings will now be ready for staking. Draw a little earth up to them first, and see that twiggy branches are supplied near the ground for the plants to cling to right away. Make another sowing.

Broccoli should now be sown after the seeds have been coated with red lead. For the autumn supply Veitch's Self-protecting is very good; for winter, Snow's Winter and Purple Sprouting are both good in their way; and for spring I can recommend Flower of Spring and June Monarch.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mans, Midlothian.

NEW AND RARE PLANTS.

Primula Purdomii.—A remarkable new species from Fochow, West Kansu, and probably the most distinct of a genus rich in good things. The 4-inch to 6-inch long lanceolate leaves with the stems and calyces are covered with a white farina. The pale lilac, yellow-eyed flowers are borne in umbels on 8-inch-high peduncles, the umbels six to twelve flowered. The flowers are delightfully fragrant. The new-comer is said to be quite hardy. From Messrs. James Veitch and Sons, Limited, Chelsea. First-class certificate.

Omphalodes Cappadocia.—A lovely blue, white-eyed species of distinct habit and tree growth. The flowers are profusely borne on 8-inch-high stems. The leaves are ovate-acuminate, deeply nerved, 1½ inches long and 1 inch broad. A pretty plant for the rock garden or alpine-house. From Mr. M. Prichard, Christchurch, Hants. Award of merit. Both were shown before the Royal Horticultural Society on the 18th inst.

CHARRING TIMBER FOR PROTECTION.

OF the numerous expedients for preventing decay in fencing timber, charring is perhaps the simplest. Rather an old-fashioned remedy, its use is dying out, and creosote finds more favour in modern fencing. There is more in charring, however, than may appear at first sight, and it is not done merely as a surface protection against wind and weather. It is, in fact, a very useful form of preservative, as the charring process not only forms an outer covering to the timber which is fairly good proof against insects and fungi, but it acts as a protection to the inner layers of the wood in a manner not perhaps always realised. The charcoal is itself almost indestructible after the post has been buried, but the protection of the deeper layers of timber is due to their being saturated by a layer of resins, tannin and similar material, which the heat from the fire drives inwards, and, to make this effective, about half an inch of charcoal should be formed.

A tendency to crack is, no doubt, one of the disadvantages of charring, but if the wood is thoroughly burnt and not merely surface scorched, there is much less danger of this occurring. In any case, tarring in addition is advisable, as it more effectually seals up the wood from the entrance of water and air, and this is the one thing needful. There is, of course, some damage done to the wood, and a proportionate amount of weakness, but far less than occurs naturally at the point where charring is required—a little above and below the ground-level. Cracks in the timber should be specially avoided in this form of preserving timber as compared with creosote or similar fungicides, G. T.

DAFFODIL NOTES.

Daffodils in Pots.—I joined Mr. Walter Ware and Mr. Christopher Bourne while they were enjoying a good supper at "The Windsor" the other night. The subject of growing choice varieties in pots was touched upon. You should have heard them talk. I am not going to repeat all they said, and I do not want anyone to write to such busy men to ask them. Well, they were most enthusiastic, and I do not think they ate

Robert Sydenham's and Mr. C. Bourne's, every group had its own seedlings, to be a bit Irish. Messrs. R. H. Bath, Messrs. Cartwright and Goodwin, Mr. F. Herbert Chapman and Mr. Watts, to say nothing of Messrs. Barr and Sons and Mr. Wilson, displayed samples of their hybrids. This, again, is but typical of what is to my certain knowledge going on in several amateurs' gardens. It is food for reflection for both dealers and buyers, for it must influence prices. I think everyone was agreed that the collection which Mr. A. M. Wilson staged was an excellent one. He had

samples of that fine all-red cupped Plectaz Rubellite and the almost equally bright incomparabilis Robespierre. He had beautiful yellow trumpets and no less taking giant Leedsus and giant "incomparabilis." One which was numbered 179 was a great spider-looking thing with a cup of a striking red orange so large that one almost imagined one's self among the Dutch cheese in the marketplace at Alkmaar. Others of this type were Cedric, a rather pale yellow, with that curious withered look in the perianth which always suggests a chill; and the Hon. J. R. Seddon (4½ inches by 1½ inches by 1¼ inches), a more pointed flower, with a primrose perianth and a deep yellow cup. I have seen photographs of many Australian and New Zealand flowers, but this is the first time I have seen it (to know it) in the flesh. I heartily congratulate Mr. J. Biggs of Christchurch, New Zealand, on being the raiser of a variety that can well hold its own among Mr. Wilson's gems. A bloom which very much appealed to me was Buckram, a flat, show flower with the palest of primrose perianths and a pale lemon yellow cup with a band of soft red. Size, 3½ inches diameter of perianth, three-quarters of an inch diameter of the eye. Two varieties of a moderate price which I feel I must mention are Diogenes, a fine pale bicolor Ajax, and Fleetwing, a bicolor incomparabilis. Messrs. Barr and Sons were deservedly awarded a silver-gilt Flora medal. They had at least 100 different seedlings—of course, of varying grades of goodness—a gentle reminder that the "old original" is not worked out yet. There was the immense yellow trumpet Ajax Atlas (5 inches by 2 inches by 1½ inches) bearing all

NARCISSUS SYCORAX, A NEW CYCLAMINEUS SEEDLING OF RICH YELLOW COLOUR. (Two-thirds natural size.)

as much as they otherwise would have done. You can draw your conclusions. I know what they will be. I will supplement them by saying pot early—pot very early—if you wish for the maximum of size and beauty in your flowers and the maximum of enjoyment for yourselves.

March 18 at Vincent Square.—It is proverbially difficult to foretell events, but the advent of seedling Daffodils in increasing numbers every year makes one wonder what will happen in the not very distant future. With the exception of

these kinds on its shoulders as it were, with a leaf almost broad enough (1¼ inches) to make a boat to take them down the Thames. As nearly all were only under numbers, it is impossible to describe them. Battle Axe, a giant red-cupped Nelsoni-looking flower, took my eye for one, and so did Sycorax, a Dutch cyclamineus seedling which has a good constitution and is a rapid increaser. It is very early and has the well-known reflexed perianth of its parent. It is, however, considerably larger in all its proportions. I fancy

it will make an ideal plant for the rockery or for pots. Blazing Star belongs to the garden or decorative type. It is a loosely-built yellow incomparabilis with a decided red edge to the cup. I have not grown it myself, but I am assured it does not burn. An out of the common but charming little flower, the result of crossing *calathinus* with *minimus*, was to be seen in Little Queen. The small trumpet is ivory white and the perianth pale lemon. I think such little things, if they prove to be good doers, will have a real use in these days of the rockery mania beyond their mere botanical interest. More comments on flowers I must reserve till next week.

Clip for Names at Shows.—A certain Mr. W. F. Mitchell of the Midland Daffodil Society one day lately had a happy inspiration and promptly sat down and thought out a simple contrivance for attaching the names of the flowers to the vases in which they are shown on the exhibition stand. He thereupon made a sample, and then took the very wise step of showing it to the governing director of Robert Sodenham, Limited, who in turn brought it to London for expert opinion, which I am sure was more than favourable. The upshot is that it is now being made as quickly as possible, and I hope to see it before the season is

A NEW CLIP FOR HOLDING A NAME CARD.

over figuring at some of our shows. The illustration fully explains the principle of the contrivance, which is simplicity itself—nothing, in fact, but a small steel spring which clasps the vase, and a properly-adjusted holder for displaying the name card. Everyone will say when they see it, "Why did no one ever think of it before!" I do not think it will stop short with us Daffodil people.

A Daffodil Year Book.—The Royal Horticultural Society's Narcissus committee, at its meeting on the 18th inst., approved certain recommendations with respect to the publication of a year book. I hope that this widely-wanted annual will make its bow to the public before the summer is over. I have undertaken to make a list of varieties which have received awards during the present season from all societies other than the Royal Horticultural Society. Lists of such from secretaries, especially Colonial ones in Australia and New Zealand, would be very gratefully received.

A Step in the Right Direction.—A small sub-committee has been appointed to try to devise a workable scheme whereby the scope of its awards could be enlarged. The committee has got deeply into the florist rut, and it is going to try to get out of it.

JOSEPH JACOB.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

THE GREENHOUSE.

POLYANTHUS NARCISSUS (A. B.)—On no account should the Narcissus be given any stimulant as the flowers are developing, as the blooms in embryo are contained within the bulb, and the natural nutriment derived from the soil and water is all that is needed. Too moist an atmosphere would also cause some of the buds to go rotten.

ARUM LILIES FAILING (Arum).—We regret that it is quite impossible for us to state the reasons of the comparative failure of your Arum Lilies. It may be caused by attacks of aphides, or green fly, as the spathes are developing, or by their being allowed to get too dry at times. Furthermore, the feeding seems to have been on a very liberal scale indeed, it may have been sufficient to injure the roots. We should certainly advise the giving of a less amount of stimulants, as too much is apt to set up an unhealthy condition of the plants, which affects, first of all, the flowers.

PERPETUAL CARNATIONS (T. H. H.)—The change from a clear atmosphere to a smoky district would be very detrimental to the American Tree Carnations, as also would the knocking them out of their pots and sending them a distance in the month of October. The temperature stated is correct, but if the house was kept in any way close and damp, it would be very detrimental to the Carnations, as they need a light and buoyant atmosphere. We fear nothing can now be done to restore the plants to health, and should suggest obtaining some young growing plants in small pots at the present time and shifting them into larger ones when necessary. The plants would then have ample time to become acclimatised to their surroundings during the spring and summer months.

PELAGONIUM LEAVES (N. C. L.)—Your Ivy-leaved Geraniums are attacked by a trouble very common among this class of plants. Various suggestions have been put forward as to its cause, but the most generally accepted idea is that it is set up by too liberal feeding. It may not be that your particular plants have had an excess of stimulants, as the taint in the blood may be inherited for generations, just as the human race often suffers for the excesses of its forefathers. At all events, potting or planting into some good sweet soil in which manure enters but little, if at all, will often suffice to restore them to health. Some varieties are more prone to this disease than others. In some instances a form of fungus occurs on the blotches, and for this spray the plants with a solution of permanganate of potash, prepared by dissolving the crystals in water. The solution should be made of such a strength that it is of a pale rose colour.

FRUIT GARDEN.

WASH FOR FRUIT TREES (F. N. H.)—It is almost useless trying to destroy mildew by winter spraying; but there is nothing better for summer use than potassium sulphide, at the rate of 1oz. to three gallons of water. Flowers of sulphur, dusted on while the plants are moist with dew, is also an effective preventive. Apple trees affected by mildew should have the affected shoots cut away and burned.

STRAWBERRIES IN BARRELS (Brandville).—It is now too late to make a good start to grow Strawberries in barrels for this year. The earliest runners should be obtained and planted in the barrels as soon as they are rooted in small pots. This should not be later than the first week in August. If you would like to try to produce a crop in this way this year, the only way to do so with a fair prospect of success is by purchasing strong, well-rooted young plants in pots and planting at once. An eighteen-gallon barrel is a good size to use. Holes should be bored 1½ inches in diameter at 8 inches apart, the top row of holes to be 5 inches below the top of the tub. The next row should be 7 inches below the first row, and so on to the bottom of the barrel. The bottom row should be at least 5 inches from the bottom. The barrel must have five holes bored in the bottom (1 inch diameter) to admit of drainage. Place broken potsherd over these holes to the depth of 2 inches, and then add over these thin turves, one layer only, with the grass side downwards, ramming tightly down over the drainage. On these turves place as much soil

(say, 1 inch or so in depth) as will bring it to the level of the first (bottom) holes, planting the bottom row. Turfy, loamy soil of rather a heavy texture is the best. Break the turves into lumps the size of a hen's egg, using the small soil also. To a barrow-load of this loam add half a bushel of well-rotted farmyard manure, one peck of old mortar rubble, and half a gallon of bone-meal, mixing the whole well together. The soil should be moderately dry when planting takes place.

PRUNING KENTISH COB NUT TREES (J. P.)—The Kentish Cob Nut tree is much benefited by hard pruning. This consists of cutting back the young shoots of last year's growth by one-third their length. This induces the formation of fruit-spurs lower down the shoots. These shoots should always be cut to a bud underneath the branch, as in this way it encourages side or lateral growth in the trees and prevents the branches getting too high at any time. Dead and decayed wood must be cut away, also any suckers which may form, in order that plenty of light and air may penetrate and circulate among the branches.

PEACH TREES CASTING THEIR FLOWER-BUDS (E. H.)—In many cases out of ten the cause of bud-dropping in Peach trees is the want of sufficient water at the roots during the autumn and winter. It is no use watering after the mischief is done and when the buds are dropping. Take a lesson from the Peach grown on walls out of doors. Buds seldom or ever drop on such trees. See how well soaked they are with all the autumn and winter rains. Try thorough watering with weak liquid manure every other time next autumn and winter. Do not excite the trees into premature growth by keeping the house too warm at any time. Learn again from the trees out of doors how dormant they remain until Nature forces them into growth.

KITCHEN GARDEN.

TO GROW MUSHROOMS WITHOUT HORSE-MANURE (M. F.)—Many materials have been tried over and over again, such as moss litter and freshly-fallen leaves, but without any success, and we would not advise you to begin with anything else than fresh stable manure, and that from corn-fed horses if possible.

VEGETABLES FOR EXHIBITION IN JULY (New Reader).—To be certain it will be safer to make at least two small sowings. As regards Camelliflowers, it depends whether you are going in for large varieties or smaller ones. If large ones, you should sow at once under glass in a cold frame, and again the first week in March. For smaller ones a fortnight later will do in a warm corner out of doors. Make one small sowing of Peas at the end of March, another the first week in April, and another a week later. It depends so much on the weather. For Cos Lettuce you must allow from ten to twelve weeks from the time of sowing. For Cabbage Lettuce a fortnight less will suffice.

MISCELLANEOUS.

TREE STUMP AND RAMBLER ROSES (M. G. L.)—We think it would be unwise to attempt to kill the stump of the tree with salt now, for Roses are very intolerant of salt in the soil.

COLLEGES FOR LADY GARDENERS (A Reader).—The Swanley Horticultural College, Swanley, Kent, and the Lady Warwick Hostel, Studley Castle, Warwickshire, both teach ladies the art of gardening. If you write to the Principal of either, you will obtain full information concerning them.

TREATMENT OF VARIOUS NEW ZEALAND PLANTS (New Zealand).—Cordylina australis may be grown in a greenhouse or dwelling-room from which frost is excluded, and in the milder parts of the country, such as Devonshire and Corwall, it thrives quite well in the open ground. It may be grown in a compost of two parts fibrous loam and one part peat, with a little well-rotted manure and sand. Give plenty of water at all times, keep the leaves well washed, and when the pot is filled with roots give manure-water once or twice a week. When planted out of doors it grows 12 feet or 15 feet high, and forms a stout trunk surmounted with several branches bearing large heads of leaves. *Phormium tenax* requires the same temperature, but is always seen at its best when planted out in the vicinity of water, say, about the margins of a lake or stream. It then grows into very large clumps and forms leaves 6 feet to 8 feet long. You can cultivate it in pots or large pans in similar soil to that recommended for the Cordylina, but you must give it plenty of water at all times, more particularly during the summer. *Sophora tetraptera* can be grown in a cool house likewise, but it never does so well in pots as when planted against a wall in the milder counties. It then flowers magnificently, but flowers are rarely produced by pot-grown plants. Similar soil to that recommended for the other plants will answer, except that leaf-mould may be substituted for manure. It will not require so much water as the other two, especially during the winter.

NAMES OF PLANTS.—*Mrs. Dawnport.*—*Cistus albidus* and *Neprolepis exaltata.*—*S. P. Rowlands.*—1, *Prunus Laurocerasus* (common Laurel); 2, *Rubus Aquifolium*; 3, *Prunus lusitanica* (Portugal Laurel); 4, *Ligustrum vulgare* (common Privet); 5, *Squoa agaiuca.*—*M. O. F.*—Probably *Prunus Mume*; specimen too scrappy to identify.—*G. Dean.*—*Rumex Acetosella* (sheep Sorrel).—*G. E. Blitchley.*—The common Privet (*Ligustrum vulgare*).

NAMES OF FRUITS.—*F. Crockett.*—1, Smart's Prince Arthur; 2, Nelson's Codlin.

EDITORIAL NOTICES.

Every description of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

NOTES OF THE WEEK.

A Good Green Paint.—In response to requests from several readers, we repeat the recipe for a really good green paint which first appeared in our pages in 1910. This is a mixture of paints "ground in oil" of one part black, two parts light chrome, and four parts white lead, suitably thinned in the usual way. Most of the so-called green paints used for stakes and tubs refuse to harmonise with green foliage and stems.

Manuring Strawberry-Beds.—During the next week or two it will be advisable to give the Strawberry-bed a rather heavy dressing of long, strawy manure. This will answer a dual purpose. A certain amount of nutriment will be washed from it down into the soil, and by the time the fruit is ripening, the straw will be perfectly sweet and clean, and act as a good protection against the splashing of the fruits by rain. Previous to putting on the manure we like to very lightly fork into the soil some soot and lime, about a good handful of each to a square yard.

A Beautiful Rock Garden Viola.—In *Viola floraveris* we have a delightful little hybrid Viola, raised by M. Corveon in his alpine garden, and one of the most useful rock garden plants. It is only 2 inches or 3 inches high, and bears for a long time in succession delightful little blue flowers. It has already acquired considerable favour, and should be remembered by those who are fond of these dainty hybrid Violas in their rock gardens. That it is a welcome plant in the famous garden of Sir Frank Crisp is a sufficient passport to secure the admission of this Swiss hybrid to many of our best rock gardens.

Limes at Brockley Coombe.—In the beautiful woods at Brockley Coombe, Somerset, may be seen some of the finest Lime trees in the country. A little way off the public road that runs through the coombe stand a line of eight veteran trees, the remains of what was probably a much longer avenue. The trees are of magnificent proportions, with low-spreading branches almost from the base. Some of the side branches alone are 12 feet to 14 feet in girth. That the trees are of great age there can be no doubt. They are said to be over four hundred years, while the common Poly-pody growing on the branches adds an additional charm to the picturesque appearance of these noble trees.

Official Guide to Kew Gardens.—The Board of Agriculture and Fisheries have appointed an official guide to conduct parties of visitors round the collections in the gardens, plant-houses and museums. Two tours will be made daily, Sundays, Good Friday, Christmas Day and Bank Holidays excepted. A nominal scale of charges has been authorised, and means will be taken to prevent unauthorised persons attaching themselves to the party. These tours, of which full particulars can be obtained by applying to the Director, the

Royal Gardens, Kew, commenced on April 1, and should be much appreciated by those who wish to gain an intimate knowledge of the many interesting features to be found in the gardens.

A Yellow-Flowered, Fragrant Annual. *Bartonia aurea* is a showy hardy annual with large golden yellow flowers an inch or so across, which are fully expanded in the evening, when they are very fragrant. It will thrive in the open border or in partial shade, and to produce a display during the summer months, seed should be sown in April. This annual does not like transplanting, neither ought the seedlings to be crowded. When large enough it is advisable to thin them to a distance of 4 inches. The plant grows about eighteen inches high.

"Setting" Tomato Blooms.—It is well known that bees never visit the flowers of the Tomato, and in order to secure a good yield of fruits it is necessary to adopt some artificial means of pollinating the blooms. This is usually accomplished by tapping the stakes or wires to which the plants are tied, or by pollinating the flowers with a hare's tail. A much better way of performing this work is by syringing the plants with clear water about noon, when the flowers are open. The different methods have been tried both with Tomatoes under glass and in the open, and the use of the syringe has given the best results.

Pruning Forsythia suspensa.—Although it is not necessary under all conditions to prune this plant regularly, when it is planted against a wall or trellis, or when it is grown as a bed in the open ground, an annual pruning is essential, and now, or as soon as the flowers are over, is the time to do the work. Cut all secondary branches back to within one or two eyes of the base and remove very weak shoots altogether, for it is better to obtain a comparatively small number of long, vigorous shoots than a larger number of weaker growths. As soon as the pruning is done, fork the ground lightly over about the roots and apply a generous dressing of well-rotted farmyard manure, for to keep the plants in good health it is necessary to keep the surface soil rich.

Alleged Poisoning by Ferns.—At a recent meeting of the scientific committee of the Royal Horticultural Society, Miss S. Edmonds sent an account of the death of two cats, supposed to have been caused by eating the fronds of Ferns in a dwelling-house. One had died and a second, which later betrayed the same symptoms, which were those of an irritant poison, was killed, as recovery was deemed impossible. The first was not examined, but the second was, and pieces of a Fern frond were found in the stomach. The Fern was sent for examination, and proved to be *Nephrolepis exaltata todeasides*. No record of this Fern or any of its congeners being poisonous was known to any member of the committee, but the committee would be glad to learn whether animals having access to it have been known to be poisoned.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

The Shaggy Pasque-Flower.—Owing to a misunderstanding, the illustration of this Pasque-flower (*Anemone vernalis*) on page 156 of last week's issue was stated to represent a group growing in Mr. Malby's garden at South Woodford. The photograph was taken by Mr. Malby last July in the Valois at an altitude of 8,500 feet.

The Raising of Seedling Narcissi.—For some years past *Narcissus Princess Mary* has been recommended to those who are engaged in hybridising the Daffodil as an excellent seeder and parent of fine progeny. I have for years raised numbers of seedlings from it, and many charming varieties may be picked out of them. But *Princess Mary* seedlings are mostly on the small side, and among the multitudinous things that are now being produced on all sides, size is becoming an important consideration. I wonder if any of your readers know of a large incomparably which will throw seedlings of anything like the beauty and variety that does *Princess Mary*, but of larger size. If so, I feel sure that the information would be useful to others besides myself.—A.

Iris fimbriata.—"T. M. D.'s" note and illustration of this plant on page 142 of March 22 issue are very interesting. I have grown this plant for ten years, and I never fail to flower it. The first plant I had was brought by a lady also from Rome, and she called it a "Roman Iris," but the proper name is *Iris japonica sinensis fimbriata*. I had it classified at Kew. It is a beautiful flower, but only lasts for such a short time.—J. S. HIGGINS, *Glynllwron Gardens, Carnarvon.*

I was much interested to see illustrated on page 142 of March 22 issue *Iris fimbriata*. I may say my employer sent a plant of this home from Madeira five years ago, which has done very well and flowered very freely every year since. I have grown it in a vinery for the most part, and it seems to have suited it very well. I should be pleased to know if the plant illustrated behaves in the same way as mine does, that is, that here the individual blooms, which are of a most fascinating shade of pale blue, with very fine delicate darker markings and a beautiful yellow throat, only last about twenty-four hours; but such a quantity of blooms are produced on the spikes that the flowering period lasts with me about six weeks.—DAVID MACKIE, *The Gardens, Eshott Hall, Felton, Northumberland.* [It is characteristic of this *Iris* for each flower to last only for about twenty-four hours, but, as our correspondent points out, so many are produced that a good plant always has a number of open blossoms during the flowering season. We hope next week to publish cultural details of this charming *Iris*.—Ed.]

Iris delicata.—As the very earliest of the Bearded Irises, this is a valuable little plant, although the flowers are not particularly showy.

The standards are silvery white and the falls are sulphur coloured, with rather deeper veining and a yellow beard. In our large collection of species and hybrids this is the first to flower out of doors, and so we think it deserves to be better known. It was raised several years ago by Mr. W. J. Caparne, but is still very scarce. It must be grouped with the *pumilas*, the flowers rising only from 6 inches to 8 inches above the ground. The constitution is sound and vigorous, although it does not increase so rapidly as some varieties.—R. WALLACE AND CO.

Mr. Lester Morse on Sweet Peas.—In reference to the note by Miss Hemus on page 154 of last week's issue, I am only a little dabbler in

carded the former in favour of the latter because I found Mrs. C. W. Breadmore, certainly not coarse, but stronger in growth, far freer in flowering and over a longer period; in short, a better variety all round. It is the one variety I place first in my seed order each year as being the one I feel I shall get the best results from, and as she has served me so well, I cannot be silent when her reputation is challenged. We all think our offspring far better than anyone else's, but it is indiscreet to mention it too often.—H. P. B., *Bristol.*

Chionodoxa nana.—This rare little *Glory of the Snow* is a late bloomer and is a pleasing *Chionodoxa*, although considerably smaller than any of its congeners. It hails from Crete, whence it came several years ago, but it does not appear to have been reimported for a considerable time. It has narrow leaves and small blue and white flowers, much less effective than those of its allies, but, still, pleasing and interesting. It is a good *Chionodoxa* for the rock garden. It is only 2 inches or so high.—S. ARNOTT,

Deciduous Cypress in Northern Florida.

—In *THE GARDEN* for January 11, page 23, you published an interesting article on *Taxodium distichum*, and in it reference was made to the curious swelling of the roots which takes place when the trees grow in a wet place, as is often the case. Herewith I enclose a print of a photograph I took in Northern Florida showing this formation, which might be interesting enough to publish. The appearance of the foliage may be a little difficult to understand, as, besides the leaves of the tree, there is what is known as "Spanish Moss" (*Tillandsia usneoides*) hanging from the branches. This so-called Moss is very common in Florida and forms quite a feature in the landscape, as it often hangs down for several yards. I even noticed it hanging from the telegraph wires, but as it is of a grey colour it was not possible to say definitely that it was growing there.—J. C., *Larne, County Antrim.*

The Fifty Best Alpines.—The lists of fifty best alpines given by Messrs. Arnott and Farrer in recent numbers of *THE GARDEN* are of great interest to those who, like myself, are but beginners in the art of alpine gardening. As you invite lists from your readers, I venture to offer one that was published, about five years ago, by a writer in the *Times*, whose articles

THE DECIDUOUS CYPRESS (*TAXODIUM DISTICHUM*) IN NORTHERN FLORIDA. NOTE THE PROMINENT "KNEES" THAT THE TREES HAVE FORMED.

Sweet Peas, but I always like to get the best of each colour according to the list issued each year by the National Sweet Pea Society, and I have never been disappointed with the result. The floral committee may not be the acme of perfection—none would be to all, for what would please one would offend another; but I am sure the present committee are quite as unprejudiced and capable of giving us an impartial list of the best varieties that will eventually give the best results to the people who pay money for seed and for whom it is intended, quite irrespective of raisers' names, than any committee to be nominated or headed by your correspondent. I have grown *Evelyn Hemus* and Mrs. C. W. Breadmore side by side under identical cultural conditions, but dis-

have since been published in book form under the title of "Studies in Gardening." His list is as follows (it may be noted that there are not quite fifty): *Achillea argentea*, *Æthionema grandiflorum*, *Aquilegia pyrenaica*, *A. alpina*, *Androsace carnea*, *Arenaria montana*, *Asperula Athoa*, *A. hirta*, *Campanula garganica*, *C. portenschlagiana*, *Daphne Cneorum majus*, *Dianthus alpinus*, *D. calizonus*, *D. neglectus*, *Erodium guttatum*, *Gentiana verna*, *Geranium argenteum*, *Hypericum reptans*, *Iberis saxatilis*, *Linaria alpina*, *Lithospermum prostratum*, *Nierembergia rivularis*, *Onosma tauricum*, *Oxalis enneaphylla*, *Papaver alpinum*, *Pentstemon glaber affinis*, *Phlox Nelsoni*, *P. Vivid*, *Polemonium confertum*, *Polygonum vacciniifolium*, *Primula nivialis*, *Ranunculus amplexicaulis*,

Ramondia pyrenaica, *Rosa alpina*, *Saxifraga Cotyledon*, *S. burseriana major*, *Saponaria ocy-moides*, *Sempervivum arachnoideum*, *S. Lageri*, *Silene alpestris*, *Viola gracilis* and *Veronica prostrata*. Perhaps I ought to mention that this list is called "The Fifty Best Rock Plants" (not alpine), which may account for some of its variations from the others. The writer had in a previous article given a list of the fifty best hardy perennials.—L. B.

— Had you not invited criticisms of the lists given, I should not have dared to comment on Mr. Farrer's choice of his beloved specialities. But my favourites would surely have resented my allowing them to remain unnamed, and I cannot risk their displeasure; therefore I must crave Mr. Farrer's forgiveness for carving his list. Quite apart from colour and times of blooming, I must first include *Sisyrinchium grandiflorum* and dispense with *Primula intermedia*; then I could do without *Saxifraga Cotyledon*, but not so *Calandrinia Howellii*. *Anemone sylvestris major*, sweet-scented beauty though it be, must give place to *A. nemorosa Alloum*, which I consider to be the most beautiful of all dwarf Anemones. *Rhododendron racemosum* must be there at the expense of—shall I say?—*Geranium lancastrisense*. Lastly, please let me include *Primula involvcrata*, a mass of it, in place of *P. pubescens alba*, much as I love the latter.—G. G. TRAHERNE (Captain), *Strathaven, N.B.*

Reliable Lilies for the Garden.—I am much obliged to your contributor "H. P." for supplementing on page 142, issue March 22, my list of "Reliable Lilies for the Garden." Some years ago a selection of varieties that I made at the request of the Duchess of Sutherland for a projected "Lily garden" at Lilleshall House in Shropshire was supplemented by Sir Herbert Maxwell in a similar way. I am glad your correspondent has included *Lilium Hansonii* and *L. excelsum*, which I cultivate in my garden and greatly admire.—DAVID R. WILLIAMSON.

The Advance in Yellow Roses.—During the last two decades or so we have had a vast improvement in yellow Roses. *Maréchal Niel*, *Celine Forestier* and *Rêve d'Or* were for a long time our best and most generally grown yellows among climbers, with *Isabella Sprunt*, *Mme. Falcot* and *Marie van Houtte* as dwarfier growers. Unfortunately, the first two in these selections are rather tender, but, where they do well, few among the large number of newer yellows can approach them. It is the pure yellows that I have more particularly in my mind at present, but must perforce say that there has been equal improvement in both flowers, habit of growth and general usefulness in the class of orange and golden yellows, with their many and varied beautiful shadings. The best newer yellows among the Hybrid Teas must include *Miss Alice de Rothschild*, *Gustave Regis*, *Instituteur Surley*, *James Coey*, *Le Progrès*, *Melody*, *Senateur Mascurand* and *Walter Speed*; while among the Teas we have a few grand additions in *Harry Kirk*, *Alexander Hill Gray*, *Lady Hillingdon*, *Medea* and *Sulphurea*. In the newer class of *Pernetiana* Roses *Rayon d'Or* stands head and shoulders above the rest. It is freer blooming than most in its section, and retains its depth of pure yellow right up to the last. As a rule, our other yellows have a tendency to pale very rapidly as the flowers expand. Both *Rayon d'Or* and *Miss Alice de Rothschild* are marked exceptions to this, and have been good during the widely varying seasons since their introduction.—A. P.

PRIZES FOR THE BEST ROCK GARDENS.

To further stimulate the interest that is now being taken in rock gardens, the Proprietors of THE GARDEN offer the following prizes for three photographs of a rock garden, or portions of a rock garden:

First prize : Five Guineas, or a Silver Cup of that value.

Second prize : Two Guineas, or Books of that value.

Third prize : One Guinea.

The competition is open only to the actual owner of the rock garden, or to his or her gardener. The object is to encourage good rock gardening, and preference will, therefore, be given to those rock gardens which show originality in design, and where the plants depicted are well grown. It should be distinctly understood that awards will be made to the best rock gardens, and not necessarily to the best photographs. The photographs need not be taken by the competitor, who must, however, in such cases have the written consent of the photographer for their reproduction in THE GARDEN. The competition is subject to the following rules:

1. Not more than three photographs of each garden may be sent in by one competitor.
2. Each photograph must have the full name and address of the competitor plainly written on the back in ink.
3. Successful competitors shall furnish written particulars of the rock garden forming the subject of their photographs.
4. Glazed P.O.P. prints must be sent, and each should be on a mount with not more than half an inch margin.
5. All photographs must be sent to arrive at THE GARDEN Offices, 20, Tavistock Street, Strand, W.C., not later than June 1, 1913.
6. Unsuccessful photographs sent in for competition will be returned in a sufficiently stamped and addressed envelope or wrapper is enclosed for the purpose, but no responsibility will be taken for the loss or damage of photographs submitted, although every care will be taken to return them uninjured.
7. The Proprietors of THE GARDEN reserve to themselves the right to reproduce any photograph sent in for competition.
8. The decision of the Editor will be final.

FORTHCOMING EVENTS.

April 8—Cornwall Daffodil and Spring Flower Show at Truro (two days). Devon Daffodil and Spring Flower Show at Barnstaple (two days).

April 9—Royal Caledonian Horticultural Society's Spring Show at Edinburgh (two days).

April 10—Perpetual Flowering Carnation Society's Show at Leamington (two days). East Anglian Horticultural Club's Meeting.

April 14—United Horticultural Benefit and Provident Society's Annual Meeting.

April 15—Royal Horticultural Society's Meeting and Daffodil Show (two days). Lecture by the Rev. Professor G. Henslow on "The Origin of Life—Why it is Undiscoverable."

April 16—Royal Horticultural Society's Bull Show and Primula Conference. Royal Horticultural Society of Ireland Spring Flower Show (two days). County Clare Horticultural Society's Spring Show.

SCIENCE IN RELATION TO HORTICULTURE.

STERILISATION OF SOILS.

THE subject of soil sterilisation is receiving considerable attention at present from gardeners, and especially from market-gardeners raising crops under glass. It is found that the rich artificial soils with a high water content and summer temperature used in such cases form a particularly favourable medium for the growth and development of certain forms of minute life, and that these gradually make the soil unhealthy to the roots of the crop. The soil becomes "sick," and hence useless for greenhouse work unless the sickness can be cured and health again restored to it. Some of the organisms frequent in "sick" soils are animal creatures, such as the minute worms that cause "clubbing" in Cucumbers, while others are of a fungal nature, like the parasite that produces "sleepy disease" in Tomatoes. But if these were the only inhabitants of the soil, while they would still induce disease, yet they could hardly bring about that peculiar soil condition recognised as "sickness."

For a proper understanding of the subject we must know something more about the soil, and especially understand the conditions that determine its fertility. The soil is not a mere mass of inert material; on the contrary, it teems with life; it is a world in itself. Each tiny particle of soil is surrounded by a film of water, and as these films are in touch with one another, it follows that a vast sheet of water extends throughout the entire soil. In this shallow sea of soil water uncountable numbers of bacteria "live, move and have their being," together with minute slow-moving animals (protozoa) that feed upon these bacteria as herbivorous animals feed upon grass in the upper world. The bacteria play a most important part in the nutrition of crops. Some break down the organic matter of manure, &c., and liberate ammonia; others convert the ammonia into nitrates; while others, again, can utilise the free nitrogen of the air in the interspaces of the soil. Without bacteria the soil would be barren; the food might be there, yet the crops would starve, because, unless fermentation is induced, the food material cannot be dissolved in water, and hence the feeding roots cannot absorb it. Now, under the conditions of intensive culture in a warm greenhouse, it seems that the protozoa are very highly favoured, and that as they increase enormously in numbers they reduce the population of bacteria to such a degree that their efficiency is seriously interfered with, and the soil, although excessively rich, fails to supply a sufficiency of food to the growing crops. It becomes "sick."

We can now turn our attention to sterilisation and its use in practical horticulture. In 1888 Franke discovered that by heating a soil he increased the amount of soluble foodstuff in it, while later experiments showed that chief among these were soluble compounds of phosphorus and nitrogen. In 1902 Dietrich made the important discovery that while this was true, yet at the same time certain poisonous substances were liberated on heating, but pointed out that these might be neutralised by the use of lime. Later it was noted by Schule that even without lime the poisonous properties of the soil gradually disappeared, and that the crop, growing poorly at first, afterwards made great progress in its growth.

In 1907 Russel and Darbshire found that they were able to get the same results by the use of antiseptics as others had got by heating the soil to the boiling point of water. Now this was a most important discovery, as it pointed to the real nature of the cause. It indicated a biological factor in addition to a chemical one in producing the results of sterilisation. Following up this work, Russel and Hutchinson, in 1907, published a paper in which it was first suggested that protozoa were the chief cause of soil sickness. The explanation is this: By heating the soil from 95° Cent. to 100° Cent. it is partially, not wholly, sterilised. The animal population is destroyed, but not the bacterial, at least, not entirely. By the use of an antiseptic, such as carbon bisulphide or formalin, the protozoa are killed; but the only effect upon the bacteria is to throw them into a state of rest, and when the volatile antiseptic escapes, as it will in time, the bacteria awake and renew their activities. So that after partial sterilisation, either by heat or by the use of antiseptics, when

of heated soils, it is shown that sterilisation induces the formation of both beneficial substances (guanine, for example) and harmful ones, and that for a certain length of time the harmful compounds overbalance the good effect of the beneficial. This explains the results obtained by Pickering in 1908, that seeds on heated soils germinated very badly indeed. Russel and Petherbridge have been recently engaged in an investigation on "sickness" in greenhouse soil in association with market-growers in the Waltham Cross district, London; but reference to this and other experiments dealing with more intimate details of sterilisation procedure must be held over until another opportunity. D. HIRSTON.

Royal College of Science for Ireland.

ROCK AND WATER GARDEN.

SOME UNCOMMON ALPINES.

The following notes contain a list, with cultural hints, of some good alpine plants that are not too

is very striking, being spotted with black. It has beautiful pink flowers, standing about one foot in height. It thrives well in very sandy soil.

Veronica Teucrium dubia E. C. BOWELL.—

A beautiful pink form of our common prostrate Veronica. It thrives well in any sunny position, and will be a great acquisition for the rock garden.

Anthemis Hauschnechtii.—For a white silvery foliage effect this takes first rank among all alpines I know. As it is not deciduous, it gives this beautiful effect all the year round on a well-drained, sunny position. It is about one foot in height, and has a charming yellow flower.

Lathyrus cyaneus.—The smallest of all perennial Everlasting Peas, with blue flowers, and only about six inches in height. It flowers in April, and is a very desirable plant for the rockery. It does best with me in half shade, which brings out its true beautiful blue.

Cheltenham. E. C. BOWELL.

A FREE-FLOWERING GENTIAN.

(*GENTIANA FREYNIANA*.)

How beautiful are the patches of intense blue made by alpine Gentians in their mountainous homes; but, alas, how disappointing Gentians sometimes are in lowland gardens! When planting these gems of the High Alps, they should be tried in different parts of the same rock garden, for it often happens that they succeed in one spot and dwindle away in another for no obvious reason, and this is notably the case with *Gentiana verna*, the most beautiful of all Gentians. Now and then one hears complaints about *Gentiana acaulis*, owing to the paucity of blooms, while it is well known that the intense blue colouring of Gentians in general is never so bright as when seen in the pure atmosphere of their mountain homes.

There are many forms of the Gentian in cultivation, most of which are suitable for the rock garden. One catalogue gives no fewer than forty-two species and varieties, but one might look in vain in nurserymen's catalogues for any mention of *G. freyniana*. This obscure and comparatively rare species is not unlike its near relative *G. septemfida*. The flowers are of intense blue, and the profusion in which the clusters are borne is clearly depicted in the accompanying illustration, taken in the rock garden at Kew. The home of this little-known Gentian is in the mountains of Asia Minor, and so far as it has been tried in this country it promises to give a plentiful supply of flowers that may be relied upon in successive years. The flowers are seen at their best about mid-July, and when better known this profusely-flowered Gentian will be looked upon as quite an acquisition for the rock garden. A sandy loam forms a suitable medium, but, like other Gentians, it resents disturbance at the root.

A LITTLE-KNOWN GENTIAN FROM ASIA MINOR (*GENTIANA FREYNIANA*).

the bacteria become active again they find themselves in surroundings entirely freed from their voracious enemies, and thus they feed, grow and multiply at an amazing rate, and hence, incidentally, liberate an abundant supply of food to the growing crop. The partial sterilisation of soil for forcing work, especially in Cucumber and Lettuce culture, is largely practised in the United States. Such pests as nematodes and the *Rhizoctonia* fungus are destroyed, and an increase of growth secured equal to 33 per cent. in recorded cases. Of course, great care must be taken not to overheat the soil so as to kill the resting bacteria, else inoculation with fresh bacteria from natural soil must be resorted to.

In a recently-issued Bulletin from the Bureau of Soils, Washington, dealing with the chemistry

well known, but which are worthy of extended cultivation:

Centaurea stricta.—The smallest and the gem of the genus *Centaurea*, and very suitable for the rockery, being about six inches high, with pretty blue flowers arising from silvery grey foliage. It loves a well-drained position, and increases readily by runners.

Felicia abyssinica.—An extremely beautiful little composite shrub about nine inches high, with fine leathery foliage, from which arise elegant pale blue flowers. It is very continuous in flowering, and loves a sunny spot.

Oxalis Lasiandra.—A gem for a shady position on the rockery. Its beautiful coppery foliage

THE FLOWER GARDEN.

DAFFODILS AT VINCENT SQUARE.

MARCH 18.

(Continued from page 164.)

I BROKE off my notes on the flowers exhibited on March 18 to include two items of news which I felt sure would be of much interest to Daffodil people. Going back to Mr. A. M. Wilson's group, I must not omit to mention that it contained the one flower that received an award of merit. This was Judith, an early giant Leedsii with a rather pointed-looking perianth and a good long stem. It was probably this feature, combined with its earliness, that weighed more than anything else with those who voted in its favour. Beryl was also up before the committee. A remark of one of the big men on this body has provided me with a good deal of food for reflection: "No, Mr. Chairman, you cannot give an award to such a small flower; how can you?" Poor little Beryl! Had you only been larger, this giant would have voted for you. It seems a bit hard on the small folk, this worship of size. I do the same myself in some things, I know. I like a turkey better than a snipe, but that is because life is too short to spend unnecessary time in pecking bones. Beryl had refinement, exquisite texture, pleasing shape, regularity of outline, and novelty of type (inasmuch as it is a cyclamineus hybrid), but it had not the one thing needful—size. Probably a good many readers will not agree with me about the turkey and the snipe. I would, however, like to know what they think about size in Daffodils, because, when I am called upon to judge, I feel that I am bound to pocket as far as possible my own personal leanings, and that I must try to give my rulings with due regard to the unwritten consensus of expert opinion. Letters from those interested would be most instructive to the Editor can find room for some.

Messrs. R. H. Bath's exhibit was chiefly interesting because it included a fair number of home-raised seedlings. Two white trumpets and a soft yellow one were quite first-rate. Mr. Leak, the manager, not only knows a good flower when he sees it, but he evidently knows how to make one. Two of the named varieties appealed to me very much: (1) Golden Dustman, which may be called a glorified Santa Maria with all its charm of shape and rich colouring, and with this valuable addition, a do-anywhere constitution, which I am sorry to say its prototype lacks; (2) Dream, a small but very refined Dutch seedling, which under glass comes nearly white (size $3\frac{1}{2}$ inches by $1\frac{1}{2}$ inches by 1 inch). Miss Currey bought probably the most beautiful show flower that we

have of this type when she acquired White Knight from Holland. The present variety cannot compete with it for this purpose, but for pots it must be very dainty. I think the price is somewhere about five shillings, so most of us will have to wait for it a little longer. Here and elsewhere in the hall was to be seen a vase of my favourite Bernardino. Every year it seems to grow on one more and more. I can recommend it not only for its exquisite beauty, but also for its grand constitution and power of increase.

I am told, "Shrove." Oh, these names! What are we coming to? My Celtic friend, Mr. Watt of St. Asaph, unfortunately (shall I say?) for us had an ancestor, Dr. William Owen, who was the author of our standard Welsh Dictionary and Grammar. Filial piety, no doubt, suggested its use when naming seedlings, and there they were in the hall, a whole batch of them—meomparabilis of various shapes, sizes and colouring, each little stranger with a nice little name, just as Welsh as itself. Cenig, Brevan and Hengan were the ones I liked best, the first being a large star-shaped self flower of a pleasing shade of yellow, with just a narrow band of red round its edge; Brevan, a soft yellow after Autocrat, and Hengan, a soft yellow after Frank Miles. One ugly-looking trumpet was called Debol. Our friend evidently does not agree with Miss Marie Corelli's presentment of that gentleman in one of her most famous novels to give this flower such an appellation. Beware of these innocent-looking names!

Robert Sydenham, Limited, had a good vase of that large pale meomparabilis Victory and that ultra-refined-looking Miss Leeds. Both are good for the show table, but as I have not grown them myself I can say nothing about their garden properties. A small $5\frac{1}{2}$ -inch pan of splendidly-grown N. triandrus edathinus, with ten bulbs in it, was one of the most delightful things in the show. Each bulb sends up one stem, seldom more, and each stem bears two large white, pendulous flowers, in shape like the better-known triandrus, but far more beautiful. If a small cold frame could be given up to them, there is no reason why they should not be raised from seed, which they produce in abundance if they are helped by a brush; at least I suggest it is, as the Scotch minister said, "an experiment well worth trying."

Messrs. Cartwright and Goodwin, as remarked last week, had some of their own seedlings on view. They were nothing very remarkable, with the exception of a much-trilled and irregularly-shaped giant Leedsii. One would like to see it again next year, as floral committees often say. In Marshlight they have annexed some bulbs of a very striking flower I call it an intensified Lucifer, and it only its deep red cup will hold colour like that variety, it will be a fine garden plant indeed. Mr. Wilson, who holds the bulk of the stock, is sticking to it, and it takes a tempting offer to make him part. *Soluto ambulando.*

Mr. Christopher Bourne had not the same array of novelties as he had a fortnight earlier. The highly-coloured Poetaz Scarlet Gem occupied a central position in the group. Its all-red cups and strong yellow, flat perianths give it a remarkable appearance. When one thinks of this and Mr. Wilson's Rubellite, one begins to realise the changes that

A MAGNIFICENT BLOOM OF THE LATE-FLOWERING DAFFODIL THE DOCTOR.

Seedlings occupied a considerable space in Mr. F. Herbert Chapman's group. A single bloom of Tennyson was one of the nicest things there. I was told I had once described it as a very gentlemanly flower. So it is. There is nothing obtrusive in its composition; everything is just right. Shrove is a curious, rather delicate-looking bloom, which somewhat reminded me of Dawn, with a pale primrose perianth and a citron-coloured eye, large and smooth, and as flat as a pancake; hence,

are taking place in this section. Below Scarlet Gem and equally prominent were two particularly fine, large, yellow trumpets, The Earl and The Doctor. They were a striking contrast in colour and shape. The Earl was a rich deep yellow self with a trumpet the exact counterpart of a King Alfred and a real obvallaris-looking perianth, but, of course, greatly enlarged. A very fine thing. (Size, 4½ inches over all; trumpet, 1½ inches long by 2 inches wide at the brim.) The Doctor was much paler in colouring, a sort of yellow bicolor, with a soft yellow trumpet and a deep primrose perianth of exquisite texture. The bold trumpet reminded me of Glory of Leiden with a recurved brim, while its perianth was pointed and overlapping and inclined to curve like it does in Frank Miles. (Size, 4½ inches by 2 inches by

covered with the white mealy substance known as farina. The great point about this welcome Primula is that there is every reason to hope that it will prove hardy.

BEAUTIFUL BORDER FLOWERS.

(THE HEUCHERAS)

THE genus Heuchera, commonly known as Alum-root or American Sanicle, was first introduced into this country in 1656 from Northern and Western America, but it is only of recent years that the plants have been used to any great extent for ornamental purposes. *H. sanguinea*, a species from New Mexico, introduced in 1822, is by far the best and the origin of many of the fine forms now grown, although very few of them equal the type so far

till May, the pieces being placed in sandy soil in a warm, sheltered corner and left till the autumn or following spring. By then they will have made good plants for putting in their permanent quarters. The latter method is advisable, as Heucheras hybridise so freely that seed cannot always be relied upon to come true.

A few of the best are *H. sanguinea*, *H. s. rubris*, *H. s. Profusion*, *H. s. alba*, *H. s. splendens*, *H. grandiflora*, *H. micrantha*, *H. brizoides*, *H. b. gracillima*, *H. Rosamund* and *H. zabeliana*, all of which are worthy of a place in every garden. F. G. P.

SIX ANNUALS THAT MIGHT BE MORE GROWN.

I SUPPOSE a captious critic in reading my heading might ask, "Why limit it to six; all annuals should be 'more grown'?" But the six I propose to call the attention of readers to in these notes are not yet to be found in every garden, and while I should hesitate to label them uncommon, they might with advantage be more frequently seen.

Cosmea or Cosmos: New Early-Flowering Varieties.

— The word early-flowering is important. There is no comparison between the effectiveness of these new varieties and the old Cosmos, which with difficulty was induced to flower at all before October, whereas these new kinds are in full flower in July and continue right up to the first frost. There are three kinds — White Queen, Rose Queen and Crimson King. The first two are excellent varieties, with flowers 3 inches across, borne on long stems on plants that reach 4 feet in height, with foliage that is very useful for vase and table decoration. Crimson King I found was not quite fixed either as to colour or shape of flower, and it was also later coming into bloom; so I am only here recommending White Queen and Rose Queen, and if one only is to be chosen, I prefer Rose Queen. Messrs. Dobbie have obtained an award of merit from the Royal Horticultural Society for both of these varieties. Coming from Mexico as they do, one would hardly have expected the moist weather of last summer to have suited them; but they did

PRIMULA PURDOMII, A NEW SPECIES FROM CHINA WITH PALE LILAC FLOWERS.

2 inches.) It is a very late bloomer, and of great value on this account. I think it was about the only yellow trumpet shown in the competitive classes at Birmingham last year. The bloom of The Earl was from the open, and that of The Doctor from a cool greenhouse; hence their appearance on the stage together. They were fine examples of their respective types. JOSEPH JACOB.

PRIMULA PURDOMII.

New Primulas continue to arrive, and the latest introduction is *P. Purdomii*, collected in West Kan-Su, China, by Mr. W. Purdon on behalf of Messrs. James Veitch and Sons. As described in last week's issue, page 163, the flowers of this new and very distinct species are pale lilac and delightfully scented, while the foliage is densely

as colour goes, but are of a more free-flowering habit.

They are excellent subjects for the herbaceous borders, the wild garden, and even the rock garden, making a fine show from May until the end of July, and some continue to flower on until October. Apart from their flowers, many are worthy of a place for their handsome foliage alone. The flowers are also of great value for cutting, being light and graceful and remaining fresh in water for a considerable time.

Heucheras require an open, sunny position in ordinary light, rich or peaty soil, but will not succeed in pure sand or heavy clay. They are easily propagated by seed, sown almost at any time in a cool frame and pricked out when large enough, or by division of the crowns from March

excellently here. A soil not too rich in manure should be given them; otherwise too much foliage is produced at the expense of the flowers. I sowed under a frame in March, boxed them in April, and transplanted in May to their flowering quarters. No heat is necessary to raise them, and the seed germinated very freely.

Arctotis grandis, another delightful composite, this time from the Cape, can be treated in exactly the same way. The plants are low-growing, foliage grey in colour, and tomentous or hairy. The flowers are produced on very long footstalks. They are pure white on the inside of the petal, with a wonderful blue-centred eye that brightens the silvery sheen of the petals. These latter are delicate lilac blue on the under surface. The

flowers are Marguerite-shaped—some 3 inches across, last a long time when cut, and are very beautiful. Last year suited them, as they like plenty of moisture.

Linaria maroccana Excelsior. This is most useful either in the border, where it grows 18 inches, or on a dwarf wall, where, I think, it is at its best. The number of colours one gets is astonishing. The flower itself is snapdragon-shaped in miniature. Some of the combinations are very pretty—purple and orange, light and dark blue, two shades of pink, yellow and white, dark crimson and yellow, pale lavender and yellow, pure white and dark violet. It should be sown thinly where it is to flower in April, and is smothered in blossom right up to the end of October; in fact, I had some flowers out at Christmas on a sheltered corner of the dwarf wall. A threepenny packet will give you hundred of plants.

Omphalodes linifolia.—A Portuguese Forget-me-not with grey-green foliage and purest white flowers, sometimes called Venus' Navel-wort, I believe from the shape of the seed-vessel. Sown thinly where it is to flower, only just covering the seeds, it grows about twelve inches to eighteen inches high, and makes a pretty little bush some six inches or nine inches through. It is a very old favourite with me, the foliage making a nice cool spot to rest the eye on. It seeds itself very freely, and if these are not disturbed, they will flower early in the year and make much bigger plants than the spring-sown seeds.

Platystemon californicus.—A Californian Poppywort, but there is nothing gross about this delightful little plant. Growing some 6 inches to 9 inches high, it forms a tuft, sending out its buds and flowers on 6-inch stalks. The colour is a cool cream yellow, the flowers about the size of a sixpence, with a lovely array of stamens in the centre. The flower in shape reminds one of the Grass of Parnassus; here again we have glaucous grey-green hairy foliage. Sown in March or April where it is to flower and well thinned, it makes a charming picture. Useful for the rock garden or dwarf wall, or for the border. It flowers in June, and generally flowers itself to death by

October. It seeds itself freely. I have never heard any garden name for this plant. Is there one? It should be something with cream in it!

Ionopsidium acaule.—A pretty little Cress from Portugal rarely growing above 2 inches high. It is used here for the crevices of the paved walk and dwarf wall. Quite hardy; in flower all the year round—even as I write. Its delicate pale lavender, cruciform flowers are always welcome. It prefers a damp spot and sows itself freely, the plants flowering within two months of sowing. If sown in September, it could be used to carpet bulb-beds; if in April, it will be in flower by June. If thinned out, the plants will get quite a respectable size, but I like the small ones best. Another annual of somewhat bigger habit, but still on the small side, and one that can be put to similar uses, is

Saxifraga Cymbalaria. I believe the only annual member of this large family. Small, Ivy-shaped leaves, it forms a tuft, very neat growing, some three inches high, and is covered with scores of its little golden yellow flowers all through the summer. Quite hardy, it also is in flower from self-sown seedlings as I write. It prefers a moist spot; at least, it is flourishing on a moist piece of rockwork; but this is not one of the six, and perhaps would not appeal to everyone, as I believe the others will.

Southampton.

HERBERT E. MOLYNEUX

TULIPA CLUSIANA.

This charming and dainty Tulip has found a resting-place in British gardens ever since the early years of the seventeenth century, for it is figured in Parkinson's "Paradisus," and also in the second

for some years without any particular attention, and find it lives all right, but that it only increases slowly, if at all. Its places are nice warm pockets on the rockery and the front rows of herbaceous borders. In either it looks well. It is hard to say whether it is more taking in the bud or when the flower is fully expanded. It is always slender and graceful, taking and charming. No, readers, I am not wandering; it is still a Tulip that I am describing; but it is one we gardeners all love and admire. It is "The Lady Tulip." Never was flower more appropriately named. JOSEPH JACOB.

SWEET PEA NOTES.

It is acknowledged to be the right of an Englishman to grumble at everything, and when all else fails him, which is very seldom, he falls back upon the weather. The things which he says of it would, if only approximately true, make it impossible to grow a single plant in our gardens; but, happily, there is much exaggeration, and, despite the badness, successes are achieved every year that make the worker in other lands, where the conditions are supposed to be ideal, decidedly envious. Without claiming that our climate is perfect, or even near that extraordinary state, it is my opinion that there is not much wrong. In some districts the conditions may be bad, but in another they will be good; and as afflictions in this particular direction rarely visit us in the same manner year after year, we all get our share of the best as well as the worst, which is quite fair.

Immense numbers of words have been wasted over the weather this season, and, according to the pessimists, everything is bound to fail. Sweet Peas have never suffered such a terrible time. Roses have been entirely ruined, and so on; but when the time comes to show them to our friends in the garden and against our rivals in the show, it will be found that quality and quantity are there. As far as Sweet Peas are concerned, my experience is that they are looking wonderfully well, and that the year will be an excellent one from all points of view.

A FINE COLONY OF "THE LADY TULIP" (TULIPA CLUSIANA).

edition of Gerard, under the name of *T. persica*. In common with certain other species, it seems to have been for a long time neglected, and possibly it quite died out. In the latter years of the eighteenth and at the commencement of the nineteenth century it was hardly ever met with, and when it was illustrated in the famous *Bot. Mag.* (the colloquial way of referring to the *Botanical Magazine*), it was said to be "very rare." On Plate 1390 of that publication there is an excellent illustration showing the rosy red flame up the centre of the exterior of each petal, and the deep claret eye of the pure white expanded bloom. It is worth turning up, if the volume is handy, to compare it with the colony seen in the above illustration. Speaking from memory, I should say it grows from 9 inches to a foot in height. I have had it growing in light, sandy soil in my garden

Planting.—The important cultural task of the month is planting out the stock raised from seeds sown under glass. There are many thousands of plants in small pots, big pots and boxes, and all will have to go into their flowering positions about the middle of the month. Assuredly some cultivators who are not believers in the rule to "Hasten slowly" will have put out their plants before this date, but whether they gain thereby is doubtful. It never seems to me that the considerable risk involved in very early planting is worth taking. What does one gain by planting at the end of March as compared with planting at the middle of April? Nothing, and one runs the risk that the plants will be brought to a complete standstill, which is a state that the Sweet Pea detests. As a rule, we can feel sure that if the plants are put out when the soil and the weather

are excellent about the middle of April, they will not cease progression even for a very short time.

Assuming that the soil has been fully prepared some time ago, we shall wait only for the favourable weather to accomplish our task. If the plants are splendidly rooted, as they certainly ought to be by now, and they are firmly planted in very deep holes, satisfactory advance is assured. Where the seeds were sown in pots, it is almost always wise to separate the roots, as there is a danger that they will have matted so hard that they will never get freely away from the ball if the planting is intact. Where the plants have been in deep boxes with plenty of space between them, it is improbable that this will have occurred, and planting can be done with plenty of soil on the roots, though it is doubtful whether that is an advantage or not.

Those who dread the so-called streak will be well advised to shake all the soil from the roots and rinse them in a weak solution of permanganate of potash, and to spray the plants once, twice, or three with the same solution after they are established in the ground. The extra careful cultivator who has suffered losses in previous seasons will go further and give the soil a soaking a few hours before planting, and he may use 10z. to the gallon of water for this purpose, whereas half that quantity will do well for the roots and for the plants. As it is known that the disease is most prevalent where heavy dressings of natural manures and over-generous applications of nitrogenous fertilisers have been employed, it is to be hoped that amateurs have restrained their common tendency to give excessive amounts under the erroneous impression that it is only on heavily-manured land that Sweet Peas will grow to perfection. The contrary is the case if perfection spells quality, as it should do.

1. A HYBRID TEA ROSE BEFORE PRUNING.

THE KITCHEN GARDEN.

POTATOES THAT RESIST WART DISEASE.

THE report for 1912 of the Harper Adams Agricultural College, Newport, Salop, contains some interesting particulars of Potatoes which have been tested at the college and other centres in the district with a view to ascertaining their immunity from wart disease, which is very prevalent in Shropshire. We quote the following remarks, which apply to varieties that had not been previously tested by the college authorities.

"Of the early varieties none can be recommended as suitable for general cultivation, each being deficient in some respect—colour of flesh, quality, or cropping power. Among the second earlies, Entente Cordiale and King George V. are the best, the former being the better in quality. A considerable number of maincrop varieties proved to be resistant, but few of them are suitable for general planting. Great Scot is undoubtedly the best of the varieties grown, and as it withstood the wet season well and was practically free from *Phytophthora*, it should be planted extensively as soon as the price is right. A variety not widely known is Culdees Castle. The tuber is well shaped, eyes shallow, and the plant vigorous, while the quality is very high. Irish Queen is a good firm Potato, but the eyes are rather deep and it is not of the type in request in English markets. St. Malo Kidney is of good shape, but the quality is not very high and it suffered considerably from *Phytophthora*. It is difficult to distinguish this variety from Reading Giant, Dalmeny Sun and The Lochan are also good croppers of good quality and very free from *Phytophthora*, while Flourball is well known as a Potato of excellent quality. Only a few Continental varieties proved to be resistant, and these left much to be desired."

GLOBE ARTICHOKEs.

ALTHOUGH these plants will continue bearing heads for several years in succession without being disturbed, after two or three seasons the crop is not so good as that produced by younger plants. These are easily raised by seeds or suckers, the last method being that most commonly practised, and if detached from the old stocks with care and planted during the end of March or early April a very serviceable crop of tender heads will be produced after the older plants have ceased bearing, thus prolonging the season for several weeks. Artichokes delight in a deeply-broken-up soil, with plenty of manure added. Plant the suckers in lines and in clumps of four, watering them well, should the weather set in dry, till they become established. The roots of Artichokes require ample nourishment, and in dry weather copious supplies of manure-water will be useful. H. MARRHAM

THE ROSE GARDEN.

THE PRUNING OF ROSES.

(Continued from page 160.)

THE HYBRID TEAS.

THE Hybrid Tea Roses vary greatly in habit, some very nearly approaching the Hybrid Perpetuals, others merging into the Teas, while in other directions we find varieties closely resembling the China Roses, and, again, others approximating to the Noisettes. Besides the difference in the character of the growth of the

2.—THE SAME HYBRID TEA ROSE AFTER PRUNING.

plants, there is great variation in the character of the flowers. Some carry large exhibition flowers, where form and quality will be the main consideration; others, numerous and medium-sized flowers of some substance; then there are varieties with comparatively few petals or semi-double blooms, single-flowered varieties, and varieties carrying loose clusters of bloom. Some, like *Mme. Ravary*, are short-stalked; others, such as *Liberty* and *Mme. A. Chateaux*, readily give flowers on long stalks. Again, the position in the garden becomes of importance, also the character of the soil. As a rule, a sunny position and light soil will favour floriferousness, while a heavy soil or partially-shaded situation has a tendency in some varieties to foster the production of foliage at the expense of flowers. All these matters should be considered by the pruner, as well as the age and previous culture of the plants. *John Rusk*, *Gladys Harkness*, *Charles J. Grahame* and *W. E. Lippiatt* are among those which approach the Hybrid Perpetual in habit, and may be pruned exactly in the manner described with regard to them.

Those Hybrid Teas which in their second growth are apt to push up a single strong shoot often present difficulties to the beginner. On the principle that the stronger the shoot the longer it should be left, it is not uncommon to see this strong stem left long, the others being much reduced. A common result of this treatment is to find one of the higher buds only on the strong shoot starting away, as though the plant was

endeavouring to pursue the method of growth it had found successful during the previous summer. Other things being equal, I think this is a mistake. The case is exactly that supposed by M. Forney in his third axiom of pruning. He says we give vigour to a branch by leaving it long, if all the other branches are pruned short. The long branch dominates the others, and, being higher and furnished with a larger number of eyes, it attracts to itself all the sap. Now, in the case supposed, the strong branch has already made the tree one-sided by attracting an undue proportion of the growth of the previous summer. By leaving it long and shortening the others, we still further accentuate this result. Our object should be exactly the opposite to this, namely, to correct the balance of the tree, and to do this the strong shoot should rather be reduced to less than the others than allowed to exceed them. In fact, it should only be left longer than the rest when some system of pegging down can be applied to it. Fig. 1 represents a Hybrid Tea Rose before pruning, and Fig. 2 the same Rose after being rather lightly pruned. Pruning to the extent shown in these figures would be about the right amount for a tree-flowering, strong-growing decorative Hybrid Tea of the character of La Tosca or Irish Elegance.

The unpruned Rose appears to possess three main stems and an old stump. The old stump will be at once removed, and we are then to deal with a very good young stem on the left of the figure, a fair one in the middle, and one on the right which is probably two years old, but has some of last year's branches proceeding from it. Possibly it may have been left rather long the previous year. However that may be, supposing the Rose we were treating were a full Rose on which we might expect to get some specimen flowers, such as *Caroline Testout*, *Königin Carola*, or *Pharisæer* the two stems on the left and in the centre should be reduced to about half the length shown in Fig. 2, and we should then tackle the

stem on the right of the figure. The first branch from the base crossing to the left should be reduced to about two buds, and we should then examine those going to the right. Choose the best of them and remove all the rest, and then shorten the selected branch to about two, or possibly three, buds, according to their position on the stem. We shall expect to remove the whole of this branch on the right next year, and are only now keeping it to preserve the balance of the tree and in the hope that it may break from its base in the course of the year. At the same time it must be borne in mind that these are merely general directions, any or all of which must give way to considerations arising from the actual condition of the plant, the position of the buds on the stems and the ripeness of the shoots. Again, for pruning some of the tall-growing decorative Hybrid Teas, the directions given here would be quite inappropriate. Such varieties as *Grüss an Tepplitz*, *Gustave Regis* and, perhaps, *Rosette de la Legion d'Honneur* do not flower satisfactorily if at all closely pruned. With these, I think, the best plan is to begin by selecting the shoots that are strongest and most desirable to retain; then spur in the side shoots on these to within about an inch of the stem, and remove the other shoots altogether. When this has been done, review the plant as a whole and shorten the retained stems slightly so as to get a fair-shaped bush, and cut away so much of the ends of the shoots as is found to be unripe.

TEA ROSES.

With many of the Teas the operator may exercise a large discretion in pruning, provided he is careful to notice and remove (1) all wood injured by frost; (2) unripe, sappy growths; and (3) thin spray-like shoots. This proviso, while it applies more or less to all pruning, is of special importance with the Teas. Roses like the pink and white *Cochets*, *Mme van Houthe* and *Anna Olivier* so readily produce basal shoots that the precautions necessary to encourage these with the Hybrid Perpetuals are not required, and they may either be left rather long or pruned hard back, according to the size of the bush desired. Moreover, these Teas can at any time be cut back to the old wood, if necessary, with a fair certainty of their breaking from it, and I have at times thought I have got more vigorous growth from plants of the *Cochet* type when little pruned than when they are cut hard back. They will do well with either treatment. The more upright-growing Teas, however, and those which are chiefly valuable for exhibition flowers, like *Mme. Constant Souper*, should generally be considerably shortened.

Many amateurs at first feel some difficulty in dealing with a much-branched bush of the Tea Rose type. Fig. 3 shows such a plant before pruning, and Fig. 4 the same plant after that operation. It will be noticed, however, that in Fig. 4 the photograph is taken from the opposite side of the plant to that of Fig. 3, consequently

4. THE SAME TEA ROSE AFTER PRUNING.

the two young basal shoots shown on the left in Fig. 3 appear on the right in Fig. 4. It will be noticed that the pruning has been rather light. It is possible the three thin crossing shoots retained were actually better than they appear in the photograph; but if not, it would generally be better either to remove these altogether or to spur them back to within two eyes of the stem from which they spring. The centre shoot of the fork shown on the left of Fig. 4 might also, in all probability, be taken away with advantage. It is common to find three, or sometimes more, young stems springing from the bud to which the stem was reduced the previous year, and in such cases only two at the most should be retained, and unless they are decidedly ripier or more promising than the outer stems, it is generally best to remove those in the centre altogether, shortening back the others.

THE CHINAS.

should either be pruned rather closely or very little, and both methods should be practised. By this means we get a greater continuity of flower. The unpruned Chinas begin to flower ten days to a fortnight before those that are pruned, and then second flowering fills in the gap between the first and second flowering periods of the pruned bushes.

THE NOISETTES.

The method of pruning has already been indicated. Choose the stems to be retained and remove the rest; then, if the retained stems have any side branches, spur these in to two or three buds of the main stem. Finally, if necessary, shorten the retained stems somewhat, but not more than is required by the condition of the stems, the place the plant occupies in the garden and the general symmetry of the plant. These directions apply whether the Noisette is grown on a wall, as a pillar, or as a free bush.

THE POLYANTHA POMPONS.

The position they occupy in the garden should generally determine the amount of pruning these are to receive. In beds it is best to plant them closely and cut them to the ground each year. On the other hand, on banks, or suitably placed in borders they may be left to themselves, merely removing dead wood and flower-stalks. I have on a bank three or four plants of *Marie Pavie* which have been practically untouched for some ten years, and have made nice, round, little bushes some 3 feet to 4 feet high and nearly as much through. On the other hand, *Perle d'Or* and *Cécile Brunner* are generally best with at least a moderate amount of pruning. WHITE ROSE.

3. THE ROSE BEFORE PRUNING.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Sweet Peas.—Whenever the ground is in a suitable condition, Sweet Peas may be planted out. If the site happens to be exposed to wind, the shelter of a few sprays of evergreen, or even short Pea stakes, will help them.

Clumps in Herbaceous Borders.—These are especially effective, but to ensure complete success the stations should be thoroughly well prepared. From five to eight plants will make a good clump, but they should not be planted too close together, nor should they be planted with the ball of soil intact, or they may suffer during a hot spell.

Asters, Stocks and Zinnias.—These I always think make the best plants when sown on a mild hot-bed about the first week in April, as at the time they are large enough to prick off the weather is such that they may be put out in any temporary frame, where a mat may be put over them during the heat of the day, or at night in the event of a very late frost.

Hardening Off Bedding Plants.—Providing we are not experiencing sharp frosts, several of the hardier classes of bedding plants may be removed from the heated to quite cold frames, and thus make room for the tender subjects which are growing and requiring more space almost daily.

Plants Under Glass.

Schizanthus.—Late autumn-sown plants are now rapidly developing their flowers, and will require plenty of water and manure to keep them going, especially if not overdone with pot room. Later batches should be potted on as they require it until the desired size of pot is reached.

Clarkias.—These also are very fast-growing at this season, and if big specimens are required, they may be potted into 8½-inch pots. Providing they have been carefully grown, no stopping is required to induce a bushy habit of growth; but much depends on the treatment in the early stages. A late batch of the two above-named plants may be had by sowing now a few seeds in 2½-inch pots, afterwards thinning to one plant in each pot.

Herbaceous Calceolarias.—These are now developing their flower-heads, and large plants may require a little staking out. Feed regularly, but in quite weak doses. To preserve a good colour in the foliage, regular damping among the plants must be practised, and they must be shaded from all hot sunshine.

Shrubby Calceolarias, such as *Cibran*, require similar treatment, but as they are of a much hardier nature, they may be subjected to a little heat to force them into bloom if necessary, or, on the other hand, may be grown in the cold frame till they commence to bloom. Young plants may have the leading growth pinched out, and this will make them flower from the side growths at a much later date and, by the way, make larger plants. These I find most useful for the conservatory.

Azalea indica. After blooming, these should be placed all together in a house to make their growth. Any repotting required should be done at once. Large shifts are not necessary, and a compost of peat, leaf soil, sand and a small proportion of loam suits them best. Very firm potting is essential, after which a fairly warm, moist atmosphere should be maintained till growth is well advanced, when they should be hardened off and placed out of doors.

Salvia splendens.—Early propagation of this plant is not necessary, and if good, strong cuttings are put in now and kept growing freely, they will make quite large plants by the autumn. In addition to the old and somewhat taller-growing type, it is as well to grow a few plants of the dwarf ones, such as *Glory of Zurich*, and these may be flowered successfully in smaller-sized pots.

The Kitchen Garden.

Carrots.—About this date the main batch of Carrots may be sown, providing, of course, the ground is in a suitable condition; if wet and heavy, by all means defer sowing till it breaks down to a nice fine tilth.

Vegetable Marrows.—These should now be sown in pots in a little heat, or a frame may be at liberty on a hot-bed, and if one or two seeds are planted between, say, a crop of Lettuce, they will quickly come along and take the place of the Lettuces as they are cleared.

Gourds.—Many varieties of these are edible as well as ornamental, and if treated as Vegetable Marrows they will succeed admirably in any warm garden, though for decorative effect they should be trained on posts or over pergolas.

Peas.—Continue to sow Peas for succession about every fourteen days, varying the quantity according to the requirements of the establishment.

Asparagus.—The present is a very suitable time for sowing seed. This may be sown where it is to remain as a permanent bed, or in some position from which the plants can be removed to a permanent bed in two years' time. Two year old plants may be transplanted now, having previously prepared the bed by trenching and manuring. Asparagus plants suffer very much if the roots are left exposed to wind and sun for any length of time, so such work should be carried out as expeditiously as possible, covering the young crowns to the depth of about three inches with hoe, light soil.

Fruits Under Glass.

Strawberries.—Ripening fruit should be given as much light and air as is consistent with the state of the weather, thereby adding flavour to the fruit. Cold draughts to the plants must be avoided, or mildew is likely to result. This latter may be sometimes avoided by spraying the plants with a little sulphur and soft soap before the fruits have attained any great size.

Early Peaches in pots or planted out that have passed the stoning stage should now be gone over, taking off any surplus fruit. Rather more warmth may now be given, and a thoroughly good feed of Le Fruitier or some such manure well watered in should set them swelling away, freely repeating the dose in from fourteen to twenty-one days.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Pentstemons.—Those raised from seed will not be fit for planting out for some weeks, but named varieties or selected seedlings raised from cuttings last autumn should be planted now. The Pentstemon requires liberal cultivation to do it well; therefore I would advise giving the ground a dressing of soot, fowl-manure, or bonemeal prior to forking it over.

Antirrhinums.—Seedlings should now be ready for transferring to cold frames to be hardened off. Autumn-struck cuttings should now be planted out.

Sweet Peas.—The pots or boxes may now be taken from the frame and stood in some sheltered position where they will get the full benefit of the sun and air.

Gladioli.—Dormant bulbs should now be planted. On most soils it is advisable to give these showy border plants some special soil of a light, rich nature. If planted in lines, a good plan is to draw a drill as for Potatoes, place a little of the prepared compost in the bottom, plant the bulbs at a foot or more apart, and partly fill the drill with more of the special compost. *Brenchleyensis*, *Childsii* and *Hollandia* are all good for massing.

Chrysanthemums.—Cuttings put in a few weeks ago will now be ready for boxing off or potting off into small pots. Place them at once in a cold frame and keep close and shaded for a few days, after which beware of coddling.

The Rose Garden.

Digging.—The beds and borders should be dug over with the digging-fork, so as to aerate the soil and give the quarters a tidy appearance. Where dry earth was drawn up to the stems of the plants as a winter protection, some well-rotted farmyard manure should be given, and where manure was used for protection, the ranker part of it should be removed and the remainder

ding in. Light dressings of lime and wood-ashes will also be found beneficial.

The Rock Garden.

Taking Stock.—This is one of the gayest months in the rock garden, and is a good time to take notes as to any proposed modifications in the disposition of the plants for the future. It is also a good time to make notes as to discarding, wholly or in part, varieties already in possession or for the purchase of new stock. Lovers of the cult should keep their eyes open at the Edinburgh Spring Show next week.

Plants Under Glass.

Ferns.—The young succulent fronds of several of the species have a great fascination for slugs and woodlice. The Maidenhaars are prime favourites with them. Young Lettuce leaves will attract slugs, and woodlice can be caught when sheltering under half a Potato scooped out with an aperture for admission. At night, with a candle in hand, is the time to catch the enemy red-handed. Precious gems should be stood on a small inverted flower-pot stood in a "flat" filled with water.

Winter-Flowering Begonias.—Newly-rooted cuttings must be potted off into 2-inch pots, using a light, open compost, say, fibrous loam, peat and leaf-mould in equal proportions, with a dash of sharp sand and pounded charcoal. It will be an advantage if the pots are plunged in Cocoanut fibre or flaky Beech leaf-mould; this will keep the temperature and moisture equable at the roots. Supply sufficient atmospheric moisture, and spray lightly morning and afternoon.

Camellias.—These favourites of long ago have regained some of their popularity, but the improvement in their favour is so recent that few large specimens are to be seen. They will now be out of flower, and should enjoy some rise of temperature while making their growth.

Fruits Under Glass.

Melons.—In early houses where the crop has been set, no time should be lost in supporting the fruits, or damage may ensue. Many devices—wicker-work, canvas and twine—are adopted for this purpose; but nothing, I think, equals the light, inexpensive nets sold for the purpose.

Second Thinning of Grapes.—Where the first thinning was done carefully and skilfully, this is an easy operation. It should be taken in hand two or three weeks after the first or principal thinning, and must be carried through with care, as the berries are apt to be pierced by the points of the scissors. If a cloth is spread under the bunch being operated on, the thinnings can be utilised for tarts.

The Hardy Fruit Garden.

Hoeing.—The quarters which were pointed over a few weeks ago will now be weathered and will be in good condition for hoeing. The operation will both produce a fine tilth and check the weeds, which begin to assert themselves about this period. I would here again remind the inexperienced that it is necessary to keep a sharp look-out for frost and promptly drop the nets in front of fruit trees in flower on walls.

The Kitchen Garden.

Autumn-Sown Onions.—Many cultivators still make an autumn sowing. Trebons being the favourite variety, and good, useful crops—generally immune from the fly—can be produced by this method. Now is the time to transplant either the whole crop or only the thinnings. It is taken for granted that the ground was well manured and deeply dug in autumn or winter. Apply a dressing of pigeon or fowl manure and fork it in, after which, if the soil is light, tread it hard and rake over. Lift the plants carefully by means of a fork, and plant to the line with a dibble. Adjust so that the bulb will rest on the surface of the soil. Water after planting, allow a distance of 14 inches between the rows, and plant 6 inches apart in the row.

Late Potatoes.—These must now be planted forthwith. Their name is legion and it is dangerous to dictate, but one has no hesitation in recommending such varieties as *Table Talk*, *The Provost*, *The Factor* and *Golden Wonder*. Allow 2½ feet between the drills, and plant 15 inches apart in the drills. Sow a little soot and Cross' Garden Fertiliser along the drills.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mans, Midlothian.

SEASONABLE NOTES ON CARNATIONS.

TIME was when all our Carnations were layered in the summer, and later on transferred to the positions in beds and borders where they were wanted to flower in the following year; and at the risk of being dubbed old-fashioned I am bound to confess that in my opinion such plants flowered far more satisfactorily than those that are now wintered in cold frames and put into their permanent quarters this month. One would not suggest that all varieties, in all soils and in all situations, should be left to take their chance out of doors in the winter. Unfortunately, the day for this has gone, because the modern varieties of most conspicuous merit are indubitably more tender of constitution than the majority of their predecessors. It would, however, be well if more stock was tried under the older system, as it would probably be found that many plants which are now popularly regarded as of doubtful hardiness would safely withstand the weather, and no steps are taken to prove the fact or the contrary.

Plants wintered in 3-inch pots in cold frames miss that chance to develop a perfect rooting system which those planted out always enjoy, and the consequence is that they are not so likely to make vigorous, healthy, floriferous plants in the summer months. The cramping of the roots in a restricted space, with the tendency to harden round the porous sides of the pot, cannot be overcome, and the effect must be distinctly prejudicial to the eventual results.

It does not appear to me that there is any sound reason why half the stock at least should not go into the open ground, the remainder being potted to winter under cover. The objection to this is, of course, that some of the choicest varieties do not produce a great quantity of "grass" suitable for layering, and that the method might, therefore, end in disastrous loss. This is true, and the specials might be dealt with in the more careful manner and the generalities treated more hardily, according to circumstances. The risk would be far too serious in excessively cold soils, but in thoroughly-drained gardens with naturally warmer soil the risk would be slight, if any. These things are, however, matters for future consideration. What we now have to put in hand is the planting out, and it ought to be done as soon as possible; but one should not rush it to the extent of putting the roots in a medium that was obviously in a totally unsuitable state.

Carnations are appreciative of a soil that is in good heart, but it cannot be claimed that they welcome fresh manure near their roots, or that they are markedly responsive to very generous dressings of artificial or chemical foods. Used in moderation these will prove advantageous, but the least excess will inevitably lead to trouble and disappointment. One fact is incontrovertible, and that is their decided partiality for lime in some readily available form. Unless this mineral is present, the plants do not assume that aspect of rude health which one likes so much to see, nor do they produce flowers of such outstanding excellence of quality. As far as the present is concerned, the readiest way of providing the essential lime is in the form of old lime or mortar rubbish crushed to a state approaching gritty dust, and this may be freely added where a shortage is suspected. The usual system is to dig it into the station prepared for the reception of the roots; but where the quantity at command will permit of it, more

satisfaction accrues to broadcast it over the entire bed or border and dig it in. There is then less concentration, but the plants never fail to secure the full benefit of the dressing.

When planting, the soil should be deeply loosened and made firm again. Unless it is known to be quite sweet, it is wise to put in a layer of fresh loam for the roots to rest upon, and if they can be packed in the same material, so much the better. In any event, they must be firm without being so tightly fixed that extension is impossible. If birds are known to do injury, it will be well to put black thread or cotton over the plants. The surface must be frequently lightly pointed over as well with these as with plants that have wintered out of doors.

F. R.

NOTES ON AURICULAS.

A MILD winter has caused Auriculas to become more advanced in growth than is usual at this time of the year. Many plants are showing good trusses fairly well advanced. In the green-edged section these should be encouraged, as they are more slow in opening; this applies particularly to such notoriously slow growers as Mrs. Henwood

Acme among the white edges, is in a forward state, and wherever this is so it will be well to give the plants cool quarters in order to delay them opening quite so soon, but at the same time do not let frost touch them. Cover frames with mats as soon as the sun goes down, and keep as warm as possible at night by keeping out cold, not by applying artificial heat.

Sets are in a forward state, and if mild weather prevails will need to be kept cool if the best flowers are to be seen in good form at show-time. I am writing from the point of view of an exhibitor at the shows. By keeping cool I mean shaded from bright sun during the warm part of the day.

Disbudding should be done as early as the state of the pups will allow. Do not let the plants suffer from lack of moisture, but at the same time guard against excessive watering. Alpines are coming along well, and, providing we do not get an April with the weather and heat of midsummer, as was experienced last year, very good blooms should be seen at the shows this year.

G. J. S.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—*The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.* The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

VIOLET LEAVES FOR EXAMINATION (L. C. F.).—The Violets are affected by the fungus *Homodendron cladosporioides*, which is the parasitic form of *Cladosporium herbarum*. It is usually only leaves that have been weakened by some uncongenial conditions that fall victims to this fungus; but, at the same time, it does much harm itself. All attention should be given to drainage and ventilation, and the plants should be sprayed with potassium sulphide, 1oz. to three gallons of water.

PÆONIES AND VIOLA (H. J.).—The herbaceous Peony is one of the hardiest subjects so far as its roots are concerned (occasionally the flower-buds suffer from the effect of late spring frosts). The occurrences are rare, however, and even then only a bud or two may be affected. You cannot plant Peonies at this season with success. Viola Mrs. C. F. Gordon is a fancy bluish purple in colour, with a lavender blotch on each petal. These markings are constant in some districts and variable in others. Mrs. F. W. R. Johnstone, Cottage Maid and Countess of Kintore are other blotched varieties.

EARLY-FLOWERING CHRYSANTHEMUMS (C. W. E.).—The following are good and reliable sorts: Abercorn Beauty (orange, shaded bright crimson), Blush Beauty (blush), Horace Martin (yellow), Chatillon (orange and ochre yellow), Goocher's Crimson (rich crimson), Mme. Gastur Perier (creamy white and pink), Mme. Marie Massé (ilac mauve), Mrs. A. Willis (yellow, shaded and striped red), Nina Bick (bronzy red), Roi des Blancs (pure white), White Massé (white, sometimes tinted pink), Perle Chatillonnaise (creamy white, shaded peach), J. Bannister (lilac yellow, shaded bronze), Claret (bright claret) and Dame Blanche (pure white).

BLUE-FLOWERING PERENNIALS (Emilie Behm).—The great period of blue in the garden is June and July, when Iris, Delphinium and Anchusa are giving a rich display; after that time we have to be content with minor subjects, the best of which are Galega, His Majesty, Erigeron speciosus, Aster acris, A. Amellus, Campanula carpatica, C. Riversea, C. lactiflora cerulea, Eryngium oliverianum, E. amethystinum and Veronica subsessilis. You might introduce each year a few plants of Salvia patens, and A. azureus grandiflorus, which is hardy. There is also the so-called race of blue herbaceous Phloxes, which are of violet and rich purple shades; Iris, Le Mahdi, Gloire du Mare and Violet are some of them, and, planted in groups apart, they are singularly effective and good.

IRIS AND STONE WALL (H.).—The specimen sent for naming is *Pulsanaria officinalis*. The Iris, from your description, is *I. reticulata*. It is a bulbous species with 2-foot-long leafage at this time. If there is not much overhead shade, you might plant the wall of the stone well with some of the Mossy Saxifrages, as Guildford seedling, muscoides purpurea and Clibrani. *Erinus alpinus* would do in many cracks and crevices, and, nearer the top, *Aubrietia* in one or more shades. At the base you might introduce *Arenaria balearica* to climb and clothe the wall, while the small-growing Fern, *Asplenium Trichomanes*, should do quite well. In similar places we have seen the common Polygote and Hart's tongue flourish, while little pieces of Thrift and seeds of Iceland Poppies would soon make a show. The spores of the Ferns should be sown in the crevices, or, by mixing them with a little clay and water, smear them on by the aid of a brush. You certainly could sow seeds of Crocuses and Daffodils, though the latter would be years before flowering. A far better way would be to obtain the forced bulb stock of the large growers. The bulbs are usually very cheap, and in two years are quite satisfactory. Occasionally we hear of such for sale, and would communicate with you if so desired.

SEED-SOWING (Ignoramus).—You may sow seeds of Stocks and Pinks in shallow boxes of light, sandy soil in your conservatory at once. Prepare a compost of two parts fibrous loam, one part leaf-mould, and one part sand. Sift a little of the mixture through a fine-meshed sieve and stand it on one side. Place crocks or cinders in the bottom of the boxes, and over these place a layer of the coarse soil which has failed to pass through the sieve. Proceed to fill the boxes to within half an inch of the surface with the ordinary soil, and level it with a little of the fine material. Sow the seeds thickly and cover with a little of the finest soil. Water with a fine-roset watering-can, and cover each box with a sheet of glass and a sheet of brown paper. When the seedlings appear, remove both glass and paper, and keep the conservatory well ventilated. As soon as the young plants are large enough to handle, prick them off in boxes about two inches apart each way. Keep the house well ventilated, and do not allow the plants to become dry. If your ground is at liberty, you may sow some of the seeds out of doors at once. You may pot your Privil in loamy soil at once; keep the young shoots pinched back to induce a bushy habit. Unless the young plants are very leggy, there is no necessity for cutting them back when you pot them.

TREES AND SHRUBS.

SOWING GORSE SEED (C. L. C. T.).—It is scarcely possible to say how much Gorse seed is required per lineal yard for a hedge, but if you sow about forty to fifty seeds to the yard they will be quite enough. Arrange to sow the seeds over a space 9 inches wide; then, when the seedlings germinate, the plants may be thinned to 9 inches apart in two alternate rows.

EVERGREENS FOR VERANDAH WALL (S. C. R.).—The following evergreens are likely to prove satisfactory against the wall beneath your verandah. All flower well: *Camellia japonica* varieties, *Choisya ternata*, *Escallonia quacrantha* and common Myrtle (*Myrtus communis*). Good soil ought to be provided at planting-time, also proper provision made for drainage.

HEDGE UNDER ASH TREE (E. K. P.).—You will find that nothing will do well as a hedge plant on a bank composed of poor, chalky soil, under an Ash tree. The conditions are quite against anything growing satisfactorily. You might, however, trench the ground well and try *Berberis vulgaris* or common Whitethorn. The Ash roots are, however, likely to rob the hedge of all the available food material.

ABOUT BERBERIS AND ACERS (*J. B.*).—*Berberis* *Kentia* is a synonym of *B. japonica*, and differs from *B. nepalensis* in having fewer leaflets to its leaves. As a rule, *B. japonica* does not have more than nine leaflets, whereas *B. nepalensis* may have as many as thirteen or fifteen. The leaflets of *B. japonica* are generally much broader than those of *B. nepalensis*. *Acer Davidii* is a Chinese species, of less vigorous growth than *A. striatum*. The correct name of the latter is *A. pennsylvanicum*, and it is the Morse Wood of the Eastern United States. *Prunus caroliniana* and *P. ilicifolia* are distinct species. *C. ilicifolia* is a native of California. It forms a small tree 10 feet to 15 feet high, with ovate evergreen leaves 3 inches to 4 inches long, with conspicuously toothed margins. The flowers are white, borne in racemes about four inches long, and are followed by globular purple fruits. *P. caroliniana*, on the other hand, is found in North Carolina, Florida, Texas and Bermuda. It also is an evergreen tree, 15 feet to 18 feet high, with oblong or oblong-lanceolate leaves up to 8 inches long, which have entire, or almost entire, margins. The flowers are white, produced in short spikes, and are followed by round black fruits.

THE GREENHOUSE.

CYCLAMEN FLOWERS MALFORMED (*Cyclamen*).—The appearance of the Cyclamen flowers sent suggests that they were attacked by insect pests, either aphides, popularly known as green fly, or thrips, when in the bud state. Again, the damage may have been caused by migration or by too strong applications of manure. If you are a Fellow of the Royal Horticultural Society, you may, through the society, have your soils, manures, &c., analysed at a fixed price. The consulting chemist is Dr. Augustus Voelcker, M.A., F.I.C., 22, Tudor Street, New Bridge Street, London, E.C. If you are not a Fellow of the Royal Horticultural Society, he would, no doubt, carry out the analysis all the same, but the charges might be different.

TREATMENT OF POINSETTIAS (*R. T.*).—Poinsettias should, when the bracts have faded, be placed in the greenhouse and kept dry. If they are too parched up, a slight watering may be given, but very little will be needed. Then, early in May, they may be brought out, the soft parts of the tops of the shoots cut off, and the plants placed in the temperature of an intermediate house, water being given and the plants freely syringed. This will lead to numerous young shoots being pushed forth, and when these are nearly 3 inches long they are ready to be taken as cuttings. The cutting may be formed of an entire shoot with its swollen base just where it starts from the old wood, as from this spot roots are freely produced. Each cutting should be inserted in a small pot, which must be clean and well drained. A light, sandy soil must be used for the cuttings, which should then be put in a close propagating-case in a warm structure, where, if care is taken not to over-water, they will soon root. As soon as rooted, the cuttings must be exposed to the air of the structure in which the propagating-case is situated. In a short time they will be ready for a shift into pots 5 inches in diameter. A very suitable soil for Poinsettias consists of good fibrous loam, lightened by a mixture of leaf-mould, dried cow-manure and sand.

ROSE GARDEN.

BUDDING SEEDLING BRIARS LEFT OVER FROM LAST YEAR (*H. P. P.*).—Yes; you can bud the Briars this year. It will be best to cut back the tops now to about six inches from the ground, and have the soil dug shallow in between the rows.

PERGOLA FOR ROSES (*B. E. M.*).—The brick supports for your pergola should be about 15 inches square, 10 feet to 12 feet high, 12 feet apart in the rows and 14 feet between the rows. By using brick pillars you should use rather stout cross timbers, for light rustic branches look out of place with brick or stone pillars. Very often squared Oak timbers are used with such supports.

PIGEON MANURE (*Goldfinch*).—If you possess a large quantity of this, the better way would be to mix it with twice its bulk of good loamy soil and place it in a heap for some months, turning it occasionally meanwhile. Thus treated, it would be suitable for incorporating with the soil of Rose-beds in the ensuing autumn, digging it in at planting-time preferably. A peck of it put in a bag and dropped in a thirty-six gallon tub of water would constitute a weak stimulant for many plants. Twice that amount may be used for Roses in beds in the open.

ROSE FORTUNE'S YELLOW (*H. R.*).—The premature shedding of its foliage is a peculiarity of this Rose, shared by few, if any, other varieties. We have an idea the trouble largely arises from over-watering; but perhaps it is due even more so to the fact that most plants sold are grafted upon the Briar or some other foster-stock. To be successful with this lovely Rose, it should be raised from cuttings or layers, and it should be planted out, if grown under glass, in a well-drained border. The main secret of success is in the pruning. As soon as the plant has provided its crop of bloom, the flowering growths are cut hard back to the main stems. New shoots will soon appear, and the weakest of these should be removed during the summer. After growth is completed, all the side shoots are cut back hard, and weak points of all the leading shoots shortened. From the spurs we obtain the glorious blooms that are unrivalled for beauty of colouring and elegance of form. Perhaps you can take a few cuttings now and insert in sandy soil. Grow on when rooted, and by the autumn you should have some nice, sturdy plants. If grown outdoors it is best if a glass coping is erected over it, and one should be very careful that the soil is well drained.

FRUIT GARDEN.

PRUNING MAIDEN APPLE TREES (*Euclyptus*).—Cut back the terminal shoot of the centre stem by one-third its length, and serve all the side shoots the same. This will induce young shoots to grow from their base in due time, and so furnish a foundation of a system of permanent branches for the tree. If this were not done, the trees would run into tops, leaving the bottom bare of silver-buds.

SILVER-LEAF ON PEACH TREES (*H. H. D.*).—The Peach shoots are attacked by the disease known as "silver-leaf," caused by the fungus *Stereum purpureum*. Affected branches seldom bear fruit and rarely recover, and it is much the best plan to cut them out entirely, cutting back beyond the point where the wood shows a brown stain. If the greater part of the tree is affected, it would be better to remove it altogether. The shoots cut away should be destroyed by fire, as it is on the dead wood that the fruits of the fungus are borne.

TOMATO PLANTS IN VINERIES (*W. C.*).—Under the best conditions possible, and in the hands of the best experts, it is difficult to make good progress in setting and properly swelling the fruit of the Tomato in the depth of winter. Our advice to you is not to force your plants unduly, but to keep them steadily growing until the days are longer and the sun has greater power. You will find that the fruit will set and swell all right then, provided the plants have passed through the winter in good health. Keep the plants on the dry side for a time and the atmosphere also fairly dry for the present, with a mean temperature of from 55° to 65° Fahr. in the daytime, dropping to 50° in the early morning, but not lower than that.

VINE-BUDS DESTROYED BY WINTER WASH (*J. L. E.*).—The safest way to proceed, we think, will be to do everything you can to encourage the Vines to break into new growth from the base of the old spurs, by keeping up a genial moist and growing atmosphere. Once you can induce the Vines to break into new growth, the bleeding will soon cease, and the new growth would, of course, bear fruit next year. Supposing, however, your Vines refuse to break into growth, you will still have your remedy for you can cut them out, say, early in May, throw them away, make a new border, and plant at once with nice healthy young Vines in pots in full growth. These will be as forward at the end of the year as if you had planted dormant Vines now, and in the meantime you have had the satisfaction of having given your old damaged Vines a chance.

KITCHEN GARDEN.

SCAB-RESISTING POTATOES (*Bishops Offley Manor*).—Your list given by the Board of Agriculture consists mostly of unfamiliar names, but the following may be recommended: Findlay's Conquest, Southern Star, Sutton's Abundance, Dobbie's Favorite, Crofter, Peacemaker, Provost, Sutton's Flour Ball, St. Malo, Kidney, Aberlady Early and Irish Queen.

GRUBS IN STEMS OF CABBAGE PLANTS (*J. S.*).—The grubs in the young Cabbages are those of the little beetle *Psyllodes chrysocephala*. They are not often found attacking the Cabbage, but have been recorded as doing so a few times. The beetle is about one-sixth of an inch long, of a bluish green colour, with reddish head and legs. It feeds on various cruciferous plants mostly near the coast, though it also occurs inland to some extent. The beetle is one of the "flea" beetles.

GROWING VEGETABLES BETWEEN APPLE TREES (*B. B.*).—The trees being planted only 8 feet apart does not leave much room for the culture of vegetables round them, bearing in mind that the ground over the roots of the trees must not be cropped. We think the best you can do is to plant two rows of early Potatoes. These would be off the ground about the end of July or early in August, and you could then sow three or four rows of Turnips, which would turn in during late autumn and early winter. This would do the Apple trees no harm, but, rather, good by the culture of the soil entailed.

BONE-MEAL FOR POTATOES (*Reader*).—Yes; it is a good manure. Spread a handful of it over a yard length of row after the sets are put in. A better artificial manure for Potatoes is the following: Half a hundredweight of guano, two hundredweight of superphosphate of lime, and half a hundredweight of muriate of potash. This should be applied at the rate of four hundredweight to the acre. Potatoes do not want much dressing for show. Wash them clean carefully without breaking the skin, but do not attempt to polish them, as judges do not like this. Select the tubers with the most even and smooth surface, with shallow eyes, of good average size, not too large nor too small.

MISCELLANEOUS.

FLANNEL WEED IN POND (*Chetwynn Leech*).—It is a good plan to rake as much of the Flannel Weed as you can out of your ponds; but the best thing to do is to apply copper sulphate at the rate of 2½oz. to 10,000 gallons of water. As you have no fish in the ponds, you might use the copper sulphate somewhat stronger, providing there are no water plants to consider and the water is not used for animals. It will be necessary to apply the copper sulphate several times during the summer. The Flannel Weed is not *Elodea canadensis*.

ST. MARK'S FLY (*H. E. H., Essex*).—The grubs sent are those of a slow-flying, two-winged fly called the St. Mark's fly, from its habit of appearing about St. Mark's Bay. There are several species, black or red in colour,

and they are frequently abundant. The larvae usually feed on decaying vegetable matter, and when this is scarce will sometimes damage the roots of neighbouring plants. Injection of carbon bisulphide at the rate of half an ounce to the square yard, the use of one or other of the soil fumigants, or the pouring of boiling water on their haunts, may be practised with advantage, while the use of lime will help to render their surroundings uncongenial to them. Although yours is a chalky district, it often happens that the top soil is devoid of lime; it easily washes out.

APPLYING LIME (*J. R. P.*).—We do not know of any article dealing fully with lime-loving plants, but there are several families of plants which have a distinct objection to lime. The chief one is Ericaceae, and very few of the plants in this Order, which includes such genera as *Rhododendron*, *Kalmia*, *Erica*, *Calluna*, *Pieris*, *Zenobia* and *Aritibus*, thrive in ground which contains lime. Conifers, as a rule, object to lime, while there are many plants which do not object to lime in the soil which would be injured were lime strewn over the ground when they were commencing to grow. If you were to spread your lime on the surface of the ground in autumn, let it lie for a couple of months and then fork it in, it is unlikely that it would injure the plants you mention; but if the same kind of lime is spread about after the plants have commenced to grow, there is little doubt but what it will kill them. It is quite likely that vegetables would be killed in the same way if the lime was sown broadcast over the young leaves, although the plants would be benefited were it applied to the ground in autumn.

BRITISH GARDENERS' ASSOCIATION (*Auld Scot*).—The British Gardeners' Association is an organisation of professional horticulturists of every grade. Its membership is widespread and influential. Its chief aims are to endeavour to obtain wages for professional gardeners commensurate with the ability necessary to be a gardener; to educate the public as to the real value of the gardener to the community; to obtain educational and travelling facilities for its members; to create a bond of fellowship among professional gardeners the world over; and to use every endeavour to raise the status of the whole profession. The conditions of membership are that a candidate for membership, if over twenty-three years of age, must have seven consecutive years of professional experience; under twenty-three years of age, five consecutive years' experience. Youths under twenty years of age are eligible to join as junior members. The subscription per annum for seniors is 2s. 6d., and for juniors 1s.; entrance-fee, 2s. 6d. and 1s. 6d. respectively. Satisfactory references must be submitted on application for membership. It would certainly be beneficial for Scottish gardeners to join the British Gardeners' Association, in more ways than one. The movement is national, and in no sense a local one. A branch exists in Edinburgh. The general secretary's address is Ulysses, Fortune Green, London, N.W.

NAMES OF PLANTS.—*E. T. W., Birkenhead*.—*Veronica lycopodioides*.—*Miss H., Hawkhurst*.—1, *Rubus spectabilis*; 2, *Tsuga canadensis*.—*A. W., Somerset*.—*Lathraea Squamaria* (Footwort).—*Alford*.—1, *Narcissus Giltier*; 2, *N. Stella superba*.—*A. P. F.*—The *Daffodils* are: 1, Sir Watkin; 2, W. P. Milner; 3, Burbidge; 4, Horsfieldii; 5, Minnie Hume; 6, Gwyther.

SOCIETIES.

ELSTREE AND BOREHAM WOOD HORTICULTURAL SOCIETY.

THERE was a good attendance of members and friends on the evening of the 13th ult., when Mr. E. Molyneux, V.M.H., of Swanmore gave a lecture on "Herbaceous Plants." The commodious dining-hall at the Elstree Schools was kindly placed at the disposal of the society by E. L. Sanderson, Esq., who also occupied the chair. The lecturer opened his remarks by speaking in eulogistic terms of the value of these plants and their increasing popularity. He then spoke of the definition of the word "herbaceous," and of the importance when exhibiting to include only those plants stipulated in the schedule. Almost any site except under overhanging trees would suffice for growing them, and as a background to the herbaceous plants, where room was available, the lecturer recommended climbing Roses of the Dorothy Perkins type trained over rough Larch or other poles. Trenching, particularly on heavy soils, should be done at least 3 feet deep, and plenty of manure and other suitable ingredients added. Unless the latter were to be freely acquired and the subsoil was poor, leave it at the bottom. Planting on light soil should be carried out in autumn, October for preference; but on heavy soils Mr. Molyneux advocated spring planting. On heavy soils lift a few plants of *Lycnis*, *Chelone barbata*, &c., and winter in a box in a cold frame. When dividing, pull the old clumps to pieces and replant the outer and more vigorous growths. The lecturer strongly advised the inclusion of bulbs, especially *Narcissi*, for spring effect in the borders, as well as others, such as *Snowdrops*, *Crocuses* and *Ilyacinths*. He strongly advised the inclusion of the better varieties, especially relating to *Asters* or *Michaelmas Daisies*, *Phlox*, *Chrysanthemum maximum* and *Montbretias*. At the close of the lecture many questions were put to the lecturer, which proved very interesting, especially in relation to the question of dividing and planting, list of best varieties, &c. Mr. E. Beckett, V.M.H., proposed a hearty vote of thanks to the lecturer, which was warmly received. Several new members were elected during the evening.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

NOTES OF THE WEEK.

Resignation of Sir Trevor Lawrence.—In two previous issues we have reported the intention of Sir Trevor Lawrence to resign his position as president of the Royal Horticultural Society. This resignation formally took place at the Council meeting on Tuesday of last week, when Sir Trevor vacated the chair. This was duly occupied by the new president, Field-Marshal Lord Grenfell. Sir Trevor has presided over the society for nearly twenty-eight years, and during that time has had the satisfaction of seeing it become the premier society of its kind in the world.

Asparagus as Ornamental Foliage.—Those who appreciate delicate green foliage with those kinds of cut flowers which do not furnish suitable leaves of their own should sow a little ordinary Asparagus seed. A row sown in some convenient part of the kitchen or reserve garden towards the end of April will, in the autumn, provide small, feathery growths for cuttings; and next year similar graceful shoots, but of larger size, will be available from early May until frost comes. Seeds of the ordinary variety are cheap, and need no special care when sown for this purpose.

The Swan River Daisy.—This pretty half-hardy annual is known under the name of *Brachycome iberidifolia*, and produces a wealth of blue flowers somewhat resembling a small *Cineraria*. It attains a height of 9 inches, and should be sown in batches or fairly large clumps to get the best effect, while as an edging plant it proves extremely useful. Seed may now be sown in the open ground, selecting, if possible, a warm, dry situation, although it is not fastidious regarding position. There is also a new variety in commerce, viz., *Purple King*, which may be described as royal purple. The colour is quite distinct, and the plant should be in great demand for beds or borders where annuals are cultivated.

An Interesting Tasmanian Shrub.—Owners of gardens in Cornwall, South Wales and Ireland would do well to make a note of *Anopterus glandulosus* for future planting, while in gardens which are less favourably situated it is well worth considering as a greenhouse plant. Belonging to the Saxifrage Order, it is very different in appearance from the other shrubby members of the family which may be grown out of doors, and its general appearance is more suggestive of *Photinia serrulata* than an *Escallonia*, *Ribes*, or *Philadelphus*. Its rather stiff branches are clothed with thick, evergreen leaves with coarsely-toothed margins, which are from 3 inches to 6 inches long and from 1½ inches to 2 inches wide. The flowers are white, with sometimes a tinge of rose on the outside of the petals, and they are borne in rather dense terminal racemes during early spring. The best results may be expected from planting it in warm, well-drained, loamy soil into which a little peat has been mixed.

Portrait of the Rev. W. Wilks.—An excellent portrait of the Rev. W. Wilks, secretary of the Royal Horticultural Society, has been exhibited at the Grosvenor Gallery, Bond Street, London, during the last week. This has been painted at the request of the Royal Horticultural Society by Mr. William Strang. We believe this portrait is eventually to be hung in the Council Chamber with those of other worthy and distinguished horticulturists.

Coloured Freesias.—There was a most interesting exhibit in the Royal Horticultural Society's Hall on April 1, when Mr. Hoog brought over from Haarlem one of Tubergen's best varieties, Conquest, and exhibited it alongside of the original first coloured hybrid, Tubergenii. The advance to a purer and clearer colour was very marked, and in our opinion fully merited an award. It was almost of the exact shade of *Rhododendron nobleanum*. When a set with real bright colours and good-sized blooms is evolved, *Sparaxis* and *Ixia* and all that ilk will have to look to their laurels; that is, of course, with the proviso that the scent factor is not all eliminated.

A Pretty Pot Plant.—In these days we do not often see examples of the genus *Diplacus*, of which there are several species, such as *coccineus*, *panicus* and *glutinosus*. It is, however, the hybrid forms of the latter that make pretty pot plants, and the flowers greatly resemble the *Musk* or *Mimulus*; in fact, they are closely allied, and we wonder if any reader has attempted to unite the two genera by hybridisation. Cuttings may now be inserted in sandy soil, and if placed in gentle heat will soon root. Grow on in a cool pit or greenhouse, and when they become large enough for 4½-inch or 6-inch pots they will produce their flowers freely. The colour is in shades of yellow and red, and the plants attain a height of 2 feet to 2½ feet.

A Showy New Zealand Shrub.—In many Cornish gardens *Brachyglottis repanda*, a New Zealand Composite, is by far the most striking flowering shrub during the present spring, for *Rhododendrons* and *Camellias*, which are usually the most conspicuous shrubs at this season, are flowering very indifferently this year. The largest bushes are frequently from 12 feet to 15 feet in height and as far across, and they carry scores of large, elegant, terminal panicles of small, cream-coloured flowers which are most effective, especially when seen against a dark background. As a foliage plant it has also attractions, for the evergreen leaves are large, green above and silvery beneath, every breath of wind disclosing the silvery surface. Wherever the climatic conditions are mild enough to allow it to survive the winter out of doors, it may be grown for once planted in ordinary garden soil it gives no other trouble than is required to prune it into shape occasionally and to remove the old flower-heads at the end of the flowering season.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Self-Sown Godetias.—I enclose a photograph of Godetias that were growing in my garden here last summer. They were self-sown from plants that were growing in the same positions in 1911. Although the photograph is not very sharp, it will serve to show the wealth of flowers that these hardy annuals are capable of producing.—M. LYELL, *Ruckmans, Oakwood Hill, Surrey.*

Fruit Trees for the North of Ireland.—It may interest your readers to have the following select list of fruit trees for the North of Ireland, none of which has failed to crop for six years in succession: Apples—Laure's Prince Albert,

valuable plant? It is too true that it is gathered in large quantities, and I hate to see the stiff bunches in Oxford Market, especially as my friend Mr. Potter, of the firm of Backhouse, who lives in the neighbourhood, tells me that this wholesale gathering must tend to decrease the number of the plant, as it is prevented from increasing in the natural way by seed. I was going one year into Oxfordshire on purpose to see the *Fritillaria* in bloom, but found that it would be useless, as the meadows had been almost stripped of flowers. Probably no bulb suffers more than the *Fritillaria*, as there is foliage on the flower-stalk. Pray, Sir, do what you can. It seems to me that the University might with great advantage buy one or two of the meadows and thus preserve their beauty.—F. A. STURGE, *Cood Ela, near Wrexham.* [We feel sure that all who love wild flowers, and who live in the Oxford district, will do all they can to prevent

The Prairie Lily in Canada.—Perhaps the following notes may be of interest to some of your readers. *Lilium philadelphicum*, the Prairie Lily, seems, from the following extract from the "Book of the Lily," by W. Goldring, to be little understood in England: "*L. philadelphicum* is a gem among the upright flowered section, and a Lily-grower who succeeds in flowering it will regard it as a triumph of his cultural skill. . . . It is a difficult Lily to permanently establish, and no one can definitely say what its exact requirements are, as so few grow it and still fewer are successful with it." This Lily is very common in Manitoba, and grows in a great variety of soils, from heavy loam on clay subsoil to sandy hill faces, but seems to prefer a sandy loam on well-drained and sunny hillsides. I have seen large masses of this Lily growing to perfection on rolling sandy plains in company with *Gaillardia grandiflora*, *Anemone patens* and *Viola delphinifolia*, all plants requiring (with us) a somewhat dry, sunny position; and while the earliest blossoms are always to be looked for on hot, dry, southern hillsides, I have never yet found a Lily in a place where the soil was moist over the winter. The bulbs usually grow at a depth of from 3 inches to 4 inches, and the soil where they grow is usually dry enough to crumble when winter sets in. The ground generally freezes to the depth of from 6 inches to a foot in November and remains frozen till early in April, so that extreme frost will not injure bulbs while dormant. If Mr. Goldring, Mr. Bowles, or some other experienced Lily-grower has a dry, sunny bank or rockery on which they would care to try this Lily, I could send them some bulbs at planting-time.—F. L. SKINNER, *Dropmore Manitoba, Canada.*

Mazus rugosus.—The note by the Wargrave Plant Farm on page 154 of March 29 issue on *Mazus rugosus*, which was shown by them before the Royal Horticultural Society on March 4 and given an award of merit, stimulates interest in a very pretty little alpine; but in view of the doubt as to the correctness of the name, it would be useful if the firm could tell us the source of their plant and the origin of the name they attach to it. *Mazus rugosus* is a very old-fashioned plant. Sweet figured it in Vol. I. of his "British Flower Garden" (1823), where he describes it as a hardy annual: "The plants begin to flower when they are scarcely two inches high and continue to bloom all the summer and ripen plenty of seeds, growing in pretty round tufts, the branches spreading prostrate on the ground in different directions. Being of small growth and spreading flat on the ground, it should be sown at the front of the flower borders. The proper time for sowing them is about the middle of April. If sown earlier they will be liable to be injured by the spring frost." Sir Joseph Hooker also describes the plant in Vol. IV. of his "Flora of British India" (1885) as a glabrous or sparsely hairy annual, without runners, with radical leaves 1 inch to 3 inches long and flowering stems from 2 inches to 10 inches long, racemes 1 inch to 6 inches, and corolla a quarter of an inch to half an inch. This is obviously a different and less valuable plant than that from the Wargrave Plant Farm. Can the plant certificated be one of the new Chinese species? Except in the colour of its flowers, it agrees well with the published description of *Mazus pulchellus* which Dr. Henry had collected in Ichang, and it is perhaps a near ally of that species.—R. W., *Colchester.*

BORDERS OF SELF-SOWN GODETIAS IN THE GARDENS AT RUCKMANS, OAKWOOD HILL, SURREY.

Bramley's Seedling, Lord Grosvenor, James Welsh, Grenadier and Allington Pippin; Pears—Hessle (against wall) and Jargonelle; Plum Victoria.—WALTER SMYTH, *Holywood, County Down.*

A Freak Narcissus.—I enclose an abnormal *Narcissus*, a freak which I have not seen before. You will see that the spathe which enclosed the bud has developed into a leaf, and there are only four petals and four stamens. The variety is *Sirius*.—W. S. P. BUNBURY (Major), *Kohsay Gardens, Bedford.* [Such examples have been previously recorded, but they are by no means common.—Ed.]

The Snake's-Head Fritillaria.—I have read with much interest your article on *Fritillaria meleagris* on page 158, issue March 29. Its quaint beauty makes a meadow where it abounds a delightful sight. Can you persuade your Oxford readers to use their influence to preserve this

the extermination of these quaint and interesting native plants. Certainly steps ought to be taken to prevent the spoliation that our correspondent states is taking place.—Ed.]

Mr. Lester Morse on Sweet Peas. With reference to the letter from "H. P. B." under the above head on page 160 of last week's issue, I need only say that my varieties can well take care of themselves, but that they are not the subject of the present discussion. What everybody who is really honestly interested in the Sweet Pea wants is restriction upon random naming and a considerable reduction in the present list. I think only an amateur committee can achieve that. In putting this idea forward I made an attempt to find a solution, but I am prepared to do my little best to help forward any better plan. I have nothing more to say.—HILDA HEMUS. [This discussion is now ended.—Ed.]

Transplanting the Tulip Tree.—In the issue of *THE GARDEN* of January 18 last, on page 30, I observe some remarks on "The Tulip Tree of America," which draw interesting attention to this desirable tree. That "it bears transplanting well" is not, however, the common experience. Significant of this I find the following direction in the catalogue of one of the largest and most reputable nurserymen in this country: "Plant only in spring and prune very closely." My purpose will be gained if those setting out Tulip Trees recognise the uncertainty of so doing with success unless care is exercised. Yet chance seedlings of the *Liriodendron* spring up on my place in the vicinity of several tall and beautiful trees growing there. *Sassafras officinale* is another of our native trees well worthy of a place in the grounds, alike for its strong green, curiously-cut foliage from spring to its clear yellow in autumn, if only it would transplant with greater facility. I have moved some fifty plants with fair success, but only by choosing the young plants and cutting them back to within 3 inches or 4 inches of the ground, and that only in the growing spring-time. Nevertheless, the *Sassafras* is difficult to extirpate from any place where it has become established, but will spring up again and again.—
W. M. RAMSAY, *New York*.

WALLFLOWERS.

One is dressed in velvet brown,
One hath got a golden gown,
Sweet and humble is their mien,
Modest handmaids for a queen.
Stoop! the thuribles they bring
Perfume all the paths of spring!

Winter winds, that stript the trees,
Had no withering power on these;
Through the rain and through the frost
Never heart of hope they lost;
Ready for their service—bliss
They will never ask but this,
Glint of sun, and light wind's kiss!

Though they win but meagre praises
'Mid the Primroses and Daisies,
Long ago a wearied mortal
Vigilant at wisdom's portal
Found the English morning hours
Sweeter for this waft of flowers.

Though in lone, forsaken places,
Brave and blithe they lift their faces;
Yet, in gardens, Brown and Gold
Please the young and cheer the old.
June's too wealthy!—I could spare
Half her splendour!—for my share
Flowers that brave the chill March air,
Debonair,
Like my Wallflowers there.

AGNES S. FALCONER, in *Country Life*.

FORTHCOMING EVENTS.

April 14.—United Horticultural Benefit and Provident Society's Annual Meeting.

April 15.—Royal Horticultural Society's Meeting and Dafodil Show (two days). Lecture by the Rev. Professor G. Henslow on "The Origin of Life—Why it is Undiscoverable."

April 16.—Royal Horticultural Society's Bull Show and Primula Conference. Royal Horticultural Society of Ireland Spring Flower Show (two days). County Clare Horticultural Society's Spring Show.

April 17.—Ipswich and East of England Spring Flower Show.

THE GREENHOUSE.

TREATMENT OF IRIS FIMBRIATA.

[In Answer to a Number of Correspondents.]

THE treatment which we recommended our correspondent "T. M. D.," whose photograph and letter were published on page 142, issue March 22, and which we are pleased to learn has been so successful, is as follows: *Iris fimbriata*, also known as *I. chinensis*, but whose latest name is *I. japonica*, is a beautiful species that many fail to flower in a satisfactory manner. Out of doors it is only in particularly favoured spots that its blossoms are produced; hence it must chiefly be regarded as a greenhouse plant. As far as soil is concerned, it is not very particular, though it prefers a fairly holding compost, such as fibrous loam, lightened by a little well-decayed manure, leaf-mould and sand. If repotting is needed, it should be done directly the flowers are over, but annual potting is, in the case of the *Iris*, by no means necessary; indeed, it often flowers in a particularly satisfactory manner as a large mass in a good-sized pot, suggestive of an *Agapanthus*. If it is not repotted, the necessary stimulus may be applied in the form of an occasional dose of liquid manure during the growing season, which is in the spring and early summer months. At that time it should be given a good light position in the greenhouse. Under this treatment it will by August have completed its growth, or nearly so, when it should be stood out of doors in a spot fully exposed to the sun. It must at that time be kept watered, but rather sparingly; that is to say, less will be needed than in the growing season. As autumn advances it should be again brought into the greenhouse and stood in a good light position there. When growth recommences, more water may be given, and the appearance of the flowers can then soon be reasonably anticipated.

WINTER-FLOWERING ZONAL PELARGONIUMS.

Two very fine Zonal Pelargoniums for winter are His Majesty, a fine rich red with a white eye, and Winter Cheer, a lovely pale shade of Turkey red ("Colour Chart," 92.1). They were originally introduced by Mr. W. H. Page of Hampton, and I have found them to fulfil all that be claimed for them. A coloured plate of the former appeared in *THE GARDEN* for March 23, 1912. Another good variety of a distinct and very pleasing shade of orange red is Cannell's Maxime Kovalesky. I was very much struck with this at the early December Royal Horticultural Society's show, and there and then acquired it. I have been told since it is excellent for winter, and, judging by the plants that have come to me from Swanley, I should say it undoubtedly is. I do like red flowers in December and January to brighten things up; hence my penchant for the above. J. JACOB.

SCHIZANTHUS.

Few annual flowers have made greater strides in public favour within the past few years. For greenhouse and conservatory they produce an unrivalled effect. At this season the young plants will grow apace, but, providing they are of bushy habit, no stopping of the growths is required. Autumn-sown plants that are developing their flowering growth may be given occasional doses of weak cow manure and soot water.

TREES AND SHRUBS.

THE HOLLIES AND THEIR CULTIVATION.

THE various kinds of Hollies are unquestionably among the most useful of all evergreens, for they exhibit a considerable diversity of habit and foliage, and the majority are amenable to cultivation in most parts of the country. The common Holly and its varieties, for instance, thrive luxuriantly in woods, copses and gardens in the South of England, while they are equally at home in many gardens in the Highlands of Scotland. Again, they are not fastidious regarding soil, for they thrive equally well on the peaty land of Woking and parts of the New Forest, on the heavy clay of the Forest of Dean and the chalk of the Chilterns, while they also grow well in very light, sandy soil and that of a gravelly character. The most unsuitable ground is that which is subject to periodical flooding or badly drained and inclined to sourness.

The Use of Hollies.—There are many uses to which Hollies may be put. Their natural position is as an undergrowth to Oak woods, and in such places examples 30 feet to 50 feet high, which have trunks a foot or more in diameter, may be met with. But they are equally adapted for planting in full sun, and are at home as isolated specimens or as clumps. Some kinds are excellent for planting as lawn specimens, while no better evergreen hedge plant can be found than the common Holly for general planting, although some of the broad-leaved kinds, such as *Hodginsii* or *Shepherdii*, stand better in the vicinity of the sea.

The Time to Plant.—Although the various Hollies lend themselves so well to general cultivation, they are decidedly difficult to establish unless a few points regarding transplanting are observed. When the roots are to be pulled about to any considerable extent, it is necessary that transplanting should be done either during late April or early May, or in August or early September. At these times the vitality of the plants is most pronounced and Nature commences at once to repair injuries, whereas, if the roots are disturbed in the dead of winter, they lie dormant for several months in cold soil, and the plants often suffer severely. Another point which is worth considering at planting-time is the reduction of the branch system to counterbalance the injury done to the roots, and it will be noticed that if a few branches are removed or shortened, the plants will be greatly benefited. Deep planting must also be avoided, for the most vigorous plants are those which have their feeding roots near the surface of the soil. One of the greatest mistakes imaginable is to bury the stems of trees, even to the depth of a few inches; yet it is often done with the idea that the plant will better withstand the effects of wind, an altogether erroneous conclusion. Should the weather be dry at planting-time, the trees must not only be well watered when planted, but syringed overhead twice a day for a few weeks. A surface-dressing of decayed leaves will also do good. If by any means a large ball of soil can be moved attached to the roots the work may be done at almost any time; in fact, plants can be moved any month in the year, but in such a case the roots are scarcely disturbed.

The Propagation of Hollies may be effected in one of three ways. All species may be increased by seeds, which take a long while to germinate,

often from one to two years. Cuttings of half-ripe shoots of species and varieties inserted in sandy soil under a hand-light, or in a cold frame in July or August, will root by the following spring, while fancy kinds may be budded or grafted upon stocks of the type. The latter, however, is not a plan to be generally adopted, unless in the case of those varieties which have weeping branches, for there is great danger of the stock growing and spoiling the scion. In some gardens the practice obtains of clipping Hollies into formal cones, and the smoother the surface of the plant, the more perfect is it considered to be. Some

so than, the type, while others rarely exceed a few feet in height. Some, again, have pendulous branches, others large or very small leaves; some have variegated foliage, others are distinguished by their very spiny or almost spineless leaves; while in still other instances the varieties are distinguished by the colour of the fruits. In selecting variegated varieties, it is always better to choose those with the variegation about the margins of the leaves, rather than those with green margins and coloured centres, for they do not revert to the type so readily as the latter. A few good green-leaved varieties are *I. A. camelliaefolia*, *donning-*

A WEEPING HOLLY (*ILEX AQUIFOLIUM PENDULA*) AS A LAWN SPECIMEN. NOW IS THE TIME TO PLANT.

people describe this clipping as pruning, and appear to consider it to be quite the correct treatment; but anything more hideous than these closely-clipped plants it is difficult to imagine. The best plants are those which assume the form of the best woodland examples, and any necessary pruning should take the form of thinning out the branches rather than clipping.

One item which often causes dissatisfaction is the failure of certain plants to produce fruit, and the fact does not appear to be generally understood that certain examples bear male flowers only and others produce female flowers only. While, however, the former plants never bear fruit, a female plant may do so even though there be no male plant near, although few of the seeds will be fertile. Those seeds which are perfect probably owe their fertility to insect agency.

The Best Varieties.—As is very well known, the common Holly (*Ilex Aquifolium*) is composed of a large number of varieties, some of which have been cultivated under one name or another for upwards of a century. They exhibit a great diversity of habit, some being as vigorous as, or more

tonensis, *handsworthensis*, *Marnockn* and *ovata*. Good variegated-leaved sorts are *Golden Queen*, *Silver Queen*, *aurea marginata*, *watereriana*, *argentea pendula*, *Handsworth Silver* and *argentea marginata*. *Pendula* is an excellent variety of pendulous habit, and *fructu-luteo* has yellow berries.

The large-leaved Hollies are mostly hybrids between either the Canary Island *I. platyphylla* and *I. Aquifolium*, or the latter species and *I. balearica*. They are generally very vigorous and have very broad leaves. *Hodginsi* or *Shepherdii*, *madrensis*, *nobilis*, *ingrescens*, *platyphylla* and *Wilsonii* are all good kinds to grow.

Among other species are numerous useful kinds. *I. opaca* is the American Holly, a useful and showy tree; *I. crenata* is a dwarf, compact kind, with small leaves, from Japan; *I. cornuta*, an oblong-leaved species, hails from China; *I. Pernyi*, a new species from the same country, is a very pretty kind; *I. integra* is interesting by reason of its spineless leaves; while *I. dipyrena* is a large-growing, useful species from the Himalaya suitable for the Southern Counties.

THE FLOWER GARDEN.

SEASONABLE NOTES ON AURICULAS.

Alpines Outdoors.—Although these are easily among the most charming of all the early-flowering plants, it cannot be said that they receive much attention. Many people, of course, fully appreciate their beauty and utility; but the majority do not do so, if one may judge by the specimens in gardens. Large, established clumps are handsome, but the variety must be one that is reasonably good, though not necessarily new, and a faulty variety should be grubbed to give space for its betters. Young plants should be raised annually from seeds as well as from cuttings, since the former are nearly sure to provide something of quality, provided the seeds are procured from a source of the first repute. The plant is wonderfully accommodating, and will flourish in practically any position in the border or the rock garden; but where it is imperative that a very hot, sunny situation has to be selected for flowering, it is wise to move the plant when the blossoming period is over to a cooler place.

Alpines from Seeds.—Notwithstanding the fact that the seeds are most irregular in germinating, and therefore one has to keep the seedpan or box under close observation for a considerable period, this is an extremely easy method of raising a stock, and it is certain that the varieties produced will be excellent. The source of worry with the amateur who has not previously sown seeds invariably lies in the fact that he sees the seedlings coming through in a most patchy way, and promptly concludes that the seeds were poor in quality. Such is not the case, however; the *Primulas* as a family are prone to exhibit this tendency. Often the late seedlings prove to be the best varieties, and the weakest must not be discarded for the strongest, as might be permissible in the case of a Parsnip. Sow so thinly that no thinning will be required, and to enable the early seedlings to be removed without disturbing the surrounding soil which contains seeds at rest or only just vegetating, and do not miss a single one because it happens to be on the puny side. The soil should be light and sandy, and the place may be a cold greenhouse, cold frame, or, failing either of these conveniences, beneath a hand-light in the open.

Alpines from Cuttings.—Those who find when their plants are in bloom that they have one or two which they particularly desire to perpetuate in increased numbers will have recourse to propagation by cuttings, which will be produced in due course. Some varieties will yield more than others, and the grower must decide the number he wants. Two and a-half inch pots containing very sandy loam answer our present purpose, and the cuttings, which must have a short length of hard stem attached, should be firmly inserted. Stand the pots in a cold frame, greenhouse, or under a hand-light, and immediately they are well rooted, plant out. Old plants can be divided after flowering if required.

W. D.

Plants in Flower.—We are on the threshold of the flowering season of the exquisite show varieties in pots. More strenuous concerted efforts ought to be made by Auricula-lovers to impress upon others the charm of these plants, their ease of culture and the small expense that they entail. It is regrettable that the most refined of all florists' flowers should be in a position such as that occupied by the show Auricula. It is known and worshipped by the few, whereas it ought to be known and worshipped by the many to do it justice. Something should be done, and the society maintained in its honour ought to do it. The plants will demand more water now and onwards, and directly the blossoms have passed their best snap off the stem just beneath the truss and leave it to waste away. The plants must not be exposed to hot sun, and the atmosphere must be sweet.

Repotting.—Perhaps the most generally satisfactory time for repotting is immediately after flowering, though it may be deferred until the late summer if more convenient. The soil should be the cleanest that can be procured, sound loam answering to all the demands made upon it; but we will postpone the discussion of this task for a week or two. F. R.

THE SCARLET WINDFLOWER FAILING.

It would be of great service, I think, were some of the readers of THE GARDEN to give their experiences of Anemone fulgens, particularly where they have cultivated it for a period of years. It is well known to many who have so grown this flower that it is, in quite a number of gardens, a most unsatisfactory plant, inasmuch as it is not only liable to be lost through the attacks of some of the diseases to which Anemones are subject, but often fails to flower regularly, and, in consequence, its value is entirely discounted.

It appears subject to practically nearly all of the recognised Anemone diseases, such as the Anemone root-mould (*Piasmopara pygmaea* Unger), the Anemone smut (*Urocystis Anemones* Pers.), Anemone cluster cups (*Ecidium punctatum* Pers.) and Anemone Peziza (*Sclerotinia tuberosa* Hedw.). I have rather frequently had specimens affected with the Anemone Peziza sent me, and have come across this in several gardens among *A. fulgens*. The most satisfactory method of dealing with all the Anemones affected with any of these diseases is to commit them to the furnace, with, perhaps, the exception of those affected with the Anemone smut, where immediate destruction of all affected leaves may eventually dispel the disease. The remedy may be a drastic one, but it is better far to lose the diseased plants than to have the whole stock affected by the ravages of these pests. Where the leaves only are affected, spraying with Bordeaux mixture or other checks may be helpful, but the drastic methods are usually the most effective with such diseases as afflict the scarlet Windflower.

When we consider, however, the failure of the plants to grow, or their unwillingness to flower

from other causes, we are on less secure lines of treatment. One has tried all the stock methods of cultivation, yet in certain places these all fail. A common prescription is a half-shaded place in rich, deeply-dug loam, with a little lime applied to it. Another, quite opposed to it, is a sandy loam in full sun. Still another is to plant in loam, leaf-soil and sand. Now, all of these fail in certain gardens, while in others *A. fulgens* can be cultivated with little care, save to plant in a border of ordinary loam.

It would, perhaps, help us were we better acquainted with the conditions under which imported tubers have been cultivated. In most cases we find that these flower very well the first season, but that they do not bloom nearly so well, if at all, the following years. It appears to the writer that very frequently—in most cases, in fact—this failure in subsequent years is due to a want of rest, and that in many parts of our kingdom the tubers are not sufficiently ripened. It does not do to dogmatise on such questions, but this is put forward as at least an indication of what the writer has found with this glowing and most beautiful scarlet Windflower. Where it does not

bloom well, it may be necessary to lift the tubers when the foliage has withered, and to give them a month or two of rest, drying them off carefully and replanting in a moderately sunny position. In wet climates the tubers are hardly ever at complete rest. The question is of more than passing importance, as no one who has grown any of the lovely varieties of *A. fulgens* is willing to confess to being beaten in the attempt to secure flowers on this charming plant.

Dumfries.

ROCK AND WATER GARDEN.

THE HARDY NYMPHEAS OR WATER LILIES.

Their Popularity.—Perhaps no flower among all the British flora is more admired than our common or wild Water Lily, *Nymphaea alba*. It was about the first of all flowers that claimed my attention nearly sixty years ago. I remember well the lovely effect that was made upon some large sheets of water in a deer park near to my home, and with most suitable surroundings, too, such, for instance, as the Bulrush (*Scirpus lacustris*). I have also seen other sheets of water covered with this Water Lily flowering in the greatest profusion. The flowers are often offered for sale in the seacoast towns of the Eastern Counties, the source of supply, no doubt, being the Broads. The true *N. alba* has a comparatively small flower, and must not be confounded with *N. candida*, which is more vigorous in every respect. Considering how very popular these old inhabitants of our ponds and lakes have ever been, it was no wonderment to think how the first of the tinted

AN EFFECTIVE GROUPING OF AQUATIC PLANTS IN A SURREY GARDEN. NOW IS THE TIME TO PLANT HARDY WATER LILIES.

hybrids took on when first imported into this country. There was, it is true, an impression in some quarters that these hybrids were not perfectly hardy. That doubt has now, I think, been completely dispelled. We have been steadily led up to the deeper tints that now obtain in some of the more recently-introduced hybrids. Now we have an ample choice from the point of colour alone, as we have also in diversity of growth. Many are the ponds and lakes that are now ornamented with these lovely flowers, and that to great advantage beyond a doubt. They look

S. ARNOTT.

well when seen at a distance, and even more so when viewed from rising ground, such, for instance, as at the Wisley Gardens of the Royal Horticultural Society, also at Gravetye Manor, Mr. William Robinson's country seat in Sussex. To inspect them more closely and to fully appreciate their individual beauty and distinct characteristics, a closer inspection needs to be made. Then we can fully realise how lovely some of the later hybrids are.

Their Utility.—Many sheets of water, both large and small, look well without any superabundance of aquatic growth. It is, however, around the margins and in cosy nooks of the larger surfaces of water that the *Nymphaeas* have a good effect. Smaller sheets of water may, in some measure, have a greater quantity of these plants, so as to produce a distinct effect. For these purposes there is now an abundant choice, both in various forms of growth and in the diversity of

this cannot be provided, it is better to thin out the crowns. This should be done without any hesitation, for two or three good crowns are very much better than twice the number in the same space. For the strongest growers 6 feet in depth of water is none too much for them. I have seen such as *N. Marhacea chromatella* doing well in as much as 18 feet of water, but I do not recommend planting at that depth. This variety is very often seen late in the season to be overcrowded. When such is the case, it points to a need of division. The flowers are often smothered by the leaf-growth also when the latter is so dense; this in no sense is desirable. Vigorous growth is also fostered and encouraged when the mud is too deep; this fact must also be contemplated when the planting is being done. I knew an instance once where there was an escape of sewage into a lake; here the growth was luxurious almost beyond description.

rather difficult to propagate such. We had such a case once in *N. Laydekeri rosea*, which never made a break. This plant ultimately died, but not before we had obtained one seedling from it.

Their Value in the Water Garden.—Water Lilies play an important part now in the effective grouping of water plants, combined with sub-aquatics and plants that associate with both and which may be fairly termed water-side plants. Taking the illustration that accompanies this article (page 181) as an example, one may note how well all the subjects comprised therein blend with one another. Here may be noted such water plants as the Arrowhead (*Sagittaria* species), the Water Sedge (*Cyperus longus*), and of sub-aquatics such as the *Astilbes* in variety. Upon firmer ground may be noted both Bamboos and *Miscanthus*, as well as the moisture-loving Saxifrage (*S. peltata*), the giant Californian species. Such a

grouping as this is most effective, the trees in the distance adding to the general attractiveness. In the immediate foreground one Water Lily gives indication of needing either deeper water or division. Allusion to the treatment of such will be noted further on. Each of the clumps of Lilies is planted at a good distance apart. This is as it should be. When possible, it is most advisable to plant for colour effect. By selecting those that can be relied upon to flower freely, this can be done. It is possible to so arrange such a water garden as this for distant effect, but personally I should favour such an arrangement as would produce a surprise. In the illustration it may be noted that no large trees overhang the water. This is as it should be, as these are not, by reason of the shade, at all favourable to healthy growth. *Caltha polypetal* (the new Kingcup) would add much to the colour effect, while both *Menyanthes trifoliata* (the Bog Bean) and *Butomus umbellatus* (the Flowering Rush) would, it not so showy, add to the attractiveness in their season. For growing in the water absolutely, *Richardia aethiopia* is most valuable in such groupings as this.

PRIMULA FORTUNEI, A BEAUTIFUL EARLY-FLOWERING PRIMROSE FOR THE ROCK GARDEN.

colours. Some, too, are suitable for large fountains, others are better even when grown in small basins of water, while it is also possible to grow them in large, shallow tubs with very good results. In whatever way they are grown they add to the attractiveness of the garden, and that, too, at a season when the garden is most frequented and more time spent therein. Small ponds and shallow pools are at times, in a measure, unsightly by reason of a scum upon the surface of the water. Where this happens to be the case, some Water Lilies should be planted. These, it is true, may not altogether dispel the bad effect produced, but they will greatly assist in doing so.

Their Freedom of Growth.—Many of the hybrids raised by M. Latour-Marhac are remarkable for their vigorous growth. For these more room is needed than is often allotted to them. When it is seen that the leaves are so dense as to force themselves out of the water, it is indicative that a greater depth is necessary for them. If

On the other hand, there are several of these hybrids that are of quite moderate growth, yet produce both leaves and flowers of large size. When I note that any particular variety possesses long petioles (or leaf-stalks), I take it as an indication that it will thrive better in deeper water. What I do not like to see is a plant that has a tendency to produce a multitude of small leaves, which lie almost upon each other at times, and with but few flowers. A few years ago this appeared to be a weakness of a few of the hybrids. I have not noted it to such an extent during the past two or three years. When it does occur, it is advisable to break up the plant into single crowns where it is possible to do so. This should be done in May, if it be possible, and with a sharp knife, aiming at a few roots to each division. These will almost invariably establish themselves during the coming summer. Some there are that flower so profusely, almost at every leaf, and do not in consequence make any back breaks. It is

It will continue in flower for a long period in the summer season.

JAMES HUDSON, V.M.H.

Gunnersbury House Gardens, Acton

(To be continued)

PRIMULA FORTUNEI.

This dainty Primrose bears a considerable resemblance to *P. frondosa*, and is of about the same size. Its flowers, however, are rather less rosy, tending more to lilac, and when poised upon the intensely white, farina-covered stalks, look extremely dainty. Unlike *P. frondosa*, the plant does not form such close resting buds; indeed, during mild winters it continues to grow the whole time, and is one of my earliest Primulas to open its attractive blossoms. It is, I believe, not quite hardy, and should be protected during cold periods, or grown in a pan, and plunged out during the milder weather. Loam, grit and leaf-mould make a compost which appears to suit this Primula excellently, while it seems to

favour a copious supply of moisture, especially during the growing season. When each plant subdivides into several crowns, it may be split up, thereby readily increasing one's stock, while pieces of sandstone partially buried about its roots greatly modify the evaporation of moisture, in addition to enhancing the appearance of the clump.
REGINALD A. MALBY.

THE ROSE GARDEN.
AN EARLY-FLOWERING PILLAR ROSE.

ROSE UNA is one of the first of the pillar Roses to greet us, which it does with large and practically semi-double blooms of a creamy white shade that passes to a clearer white when fully open. In this garden—Ken View, Highgate—it has been grown for several years, though rather badly given to attacks of mildew in the bud stage; yet one is bound to admire and speak well of it because of the free manner in which the large flowers are produced. It is rather sparse with us in sending up new growths from the bottom; they more often come halfway or more up the existing rods, which makes the September pruning a work of just thinning the head part rather than, as is mostly the case with climbers, a clearing away of complete stems from the base. However, it is rather a good thing that Una does not want too much handling, for it has, I should think, about the worst thorns of all Roses. C. T.

SEASONABLE WORK
AMONG THE ROSES.

APART from the most important work of pruning our Roses, there is much to be done during this month whenever the weather permits. Mulchings applied now, or immediately after the prunings are collected, will be a great support to the plants all through the coming season. Before mulching I would prefer to slightly move the surface soil, and if a sprinkling of bone-meal can be added just before turning this over, there are few cases where it will not be beneficial. One may be sure of the fertilising juices from these spring mulchings being of use, for the active roots of Roses will be ready to take them up at once. On the other hand, I have little doubt that a good proportion of these are lost by winter percolation taking it quite beyond the roots while in no condition to absorb or make use of the nourishment.

The nature of these mulches must be largely a matter of convenience, with a little regard to the natural constituents of the soil. But I may say

that Wakeley's Hop Manure is equally as suitable for the majority of soils as the best prepared stable manures; and if one must purchase, this, aided by the sprinkling of bone-meal, will afford the cleanest and least objectionable mulch of any that I am acquainted with.

If one must plant, or even fill up a few gaps thus late in the season, it will be well to give more attention to firmer soil around the roots, whether the plants be from the open ground or from pots. Of course, before any mulching is done, one should take good care to eliminate any suckers from the stocks the Roses may be worked upon. If this is being done at the time of pruning, on no account be tempted to use a sharp-edged knife. Keep an older and rougher-edged one specially for this purpose.

ROSE UNA, A BEAUTIFUL SEMI-DOUBLE VARIETY, GROWING ON A PILLAR.

Even on March 7 I found some green fly upon the very precocious young growths in sheltered corners upon walls and fences. Here, in the South, we have scarcely had any real check to many growths in warm quarters, and I would advise the use of the syringe freely wherever fly is visible. If one does not, he will simply be harbouring a healthy colony of enemies, which will assuredly infest the whole of the young Rose growths as soon as the first real spring days put in an appearance.

Sussex.

COLOURED PLATE.
PLATE 1469.

CLARKIAS FOR GARDEN AND GREENHOUSE.

AMONG hardy annuals there are few more beautiful and useful than the varieties of *Clarkia elegans*, of which there are now some particularly good colours obtainable. For sowing in the open garden during April where the plants are intended to flower these Clarkias are ideal: their tall yet graceful habit and the delicately-poised flowers creating bright and pleasing effects in mixed borders, large beds, or, indeed, in almost any position that is not densely shaded by overhanging trees. In common with other hardy annuals, it is essential that the seed be sown very thinly, and when the seedlings are well up they must be thinned to 9 inches or 12 inches apart to allow the plants to develop their natural branching habit. As cut flowers—these Clarkias are exceedingly pretty, possessing the merit of lasting well and lending themselves to artistic arrangement, this latter feature being well shown in the accompanying coloured plate.

Until a few years ago varieties of *Clarkia elegans* were regarded solely as flowers for the outdoor garden; but thanks to the beautiful exhibits that have been staged by Messrs. Sutton and Sons at the Royal Horticultural Society's Temple Shows and at the International Show at Chelsea last year, a great impetus has been given to their cultivation in pots. Possibly this impetus has been aided also by the introduction of several new and charming colours, the latest and most beautiful of which is Sutton's Scarlet Beauty, shown in the accompanying coloured plate, which has been prepared from a colour photograph kindly placed at our disposal by Messrs. Sutton and Sons.

For early spring decoration of the conservatory nothing is more telling than well-grown plants of this and several other varieties. For this purpose the seeds should be sown in September and the seedlings grown under quite cold treatment, just preserving the plants from frost and keeping them as near the glass as possible to encourage sturdy growth. The seedlings should be potted on and pinched back two or three times to ensure nice bushy plants. Scarlet Beauty is perhaps the brightest colouring of all, and with winter pot culture the colour comes a beautiful rich salmon pink, resembling the colour of Sweet Pea Earl Spencer. Double Delicate Pink, Double Salmon, Double White and Firefly (a bright rose crimson) are also well worthy of cultivation, both in pots and in the open border.

A. P.

DAFFODIL NOTES.

The Present Season.—The present is a "How are things looking with you?" season. The ordinary salutation is forgotten, and hands are clasped with the anxious accompaniment of the above formula. Each one hopes for the cold comfort of being told that his neighbour is like himself, for, if the truth must be told, 1913 is not a vintage year. Frosts, merodons and slugs have done or are doing their best to make the wretched Daffodil as uncomfortable as possible. Taken as a whole, the blooms in the Royal Horticultural Society's Hall on April 1 did not look up to the mark. They had that peculiar appearance which always seems to tell me that they have been short of a top-coat on more than one occasion. In our fickle climate Jack Frost is often in evidence. An extra early season like the present only makes his visits more apparent, that is all. The merodon is an even more unwelcome visitor. How to combat it is a serious question. When there are numerous gaps in our serring ranks, let us lose no time in getting our nets ready. With the advent of warmer weather he is sure to be seen. *He must then be caught.* He does not, however, account for all. Some blanks must be credited to the ubiquitous slug. Slugs have had a good time lately, and in stiff soils they have been especially active among the Daffodils. My head-gardener has lately been investigating some failures, and he frequently found the bulb quite sound, but minus roots and plus some fat slugs. Among others who talked to me at the show was Mr. Denison of Henley-on-Thames, who has a garden of stiff, clayey soil. He bemoaned the loss of his Poetaz and his Lucifer, owing to the long-continued waterlogged condition of his ground, and he then went on to say that he had been very much bothered with slugs, and that when he dug down to some of the bulbs he often found slugs enjoying a nice meal. He fancied that they ate the roots. His experience and my own are so similar, and the coincidence of his mentioning it to me when he did struck me so much, that I have inserted it here as a possible solution of other people's troubles.

A Vexed Question.—There were several varieties up for award before the committee, but only one gained the coveted distinction; that was White Emperor, a beautiful flat flower of ivory white and the palest primrose. While there was a general consensus of opinion in favour of the award, there was a sharp cleavage between members as to what it should be labelled. Here are the facts. By breeding and parentage the variety is an Ajax or trumpet, but by the Royal Horticultural Society's

measurement classification of 1910 it is an undoubted giant Leedsii, inasmuch as the segments are from one-eighth of an inch to a quarter of an inch longer than the trumpet; again, as you see it sideways, it looks like a trumpet; but if you stand straight opposite it, it has a decided Leedsii appearance. The amount of interest aroused was very great. One was continually being asked, "Is it decided?"; or, as a witty member of the Narcissus committee put it, "When is a trumpet not a trumpet?" the answer being, "On the first of April!" It has been suggested that it is on the border-line. It might be, if a trumpet was a *mule* long, but when a very big

golden trumpets—lovely things—every one of which changed hands before the day was over. Haydon's mantle seems to have fallen upon Chapman. Lissadell had far and away the largest exhibition of their own seedlings that I have ever seen. There were some nice things among them, but on the whole they would not set the Thames on fire. I am, however, pretty sure that this was only a feeler. *There are more at home.* Mr. Watts had a goodly array of novelties, all made in Wales, and again he requisitioned his ancestor's dictionary. He is very good about it at present, and does not often go beyond two syllables; but what will it be like when these are used up and,

it may be, in addition to his own he has Anglesey Bulb Farm seedlings to christen! I saw a real beauty from Colonel Cotton in the Editor's sanctum the other day. It had quite a nice name—Apricot Gem, I think, or something of that sort; but just suppose he began naming them after the parish in which he lives—Llanfair &c., &c., &c. (these etceteras refer to the word which includes a whole tale about a well before it is finished). Then there was an interesting little collection from Mrs. R. O. Backhouse of Hereford. The blooms were in an unfortunate position, right against the light, and were not seen at their best in consequence. Two cups, one a triandrus seedling and the other a red-edged, had curiously thickened margins, of the same sort of look that the excrescences on the trumpets of many frilled white have. In Engleheart's fine display, perhaps the feature above all others was the size of his largest giant Leedsii. Super-Giants would not be a bad name for them. Among Wilson's the wonderful red cups stood out; what a pity that the colour is so fleeting! In my next notes I hope to describe in some detail about a score of the newer ones at this show which took my fancy, and which are not much, if they are at all, known.

Andrew Kingsmill.—It was a sad duty that fell to Mr. Warrender when he had to announce the death of the friend who had proposed him as member of the committee. We all feel his loss.

His connection with the Daffodil goes back to earlier days than the appearance of that epoch-marking plate of Seagull and Albatross in THE GARDEN. He was a member of the celebrated syndicate that quietly absorbed all the best of the early Engleheart productions, beautiful things that are only now becoming common. His garden was largely of the semi-wild order, and here, under the partial shade of trees, he established fine colonies of the cheaper and better-known kinds. A favourite both of Mrs. Kingsmill and himself was the old small incomparabilis John Bull. It is much in the style of Autocrat. I will always connect him with it. Its name was typical of the man in more ways than one.

JOSEPH JACOB.

THE NEW NARCISSUS WHITE EMPEROR. IS IT A TRUMPET OR A GIANT LEEDSII VARIETY?

one is only $\frac{1}{4}$ inches, surely one-eighth of an inch or three-sixteenths of an inch is a very appreciable quantity. One consolation that the owners will have will be that this divergence of opinion is an uncommonly good advertisement or send-off as it begins its market life. Some of its judges may be April fools, but its purchasers were not—at least, I for one do not think so. The illustration of this famous flower which is figured on this page gives a side view of it and shows its trumpet appearance.

Generalisms on the Best Flowers.—Again seedlings were in the ascendant. Never before has Mr. F. Herbert Chapman staged such an exhibit. It was almost entirely composed of his own home-made flowers. Among others, he had six magnificent

GARDENING FOR BEGINNERS.

HOW TO PROPAGATE SWEET VIOLETS.

EXPERT cultivators pay much attention to the propagation of new stock, as they know quite well that the finest crops of flowers will result

if they possess a few roots, carefully lift and replant them in a prepared border facing east, west or even north, putting them in 9 inches apart each way. They will soon form a mass of roots and be in good condition for planting in their summer quarters. Fig 4 shows a runner with a hard crown producing small flowers and more runners,

down runners. Old plants may be divided and the separate parts planted out, but it is not the best way to increase the stock, as much strength of plant is required, and this can only be obtained from the robust suckers.

Planting the Violets in Open Borders.—In the first place it is necessary to deeply dig the soil and to put in some rotted manure. If the soil is naturally light, it must be well enriched, less manure being required where a heavier loam obtains. The latter, well prepared, is the best for Violets. Do not use fresh, strawy manure in any case, but that which is well rotted. A single row of plants may be put out between rows of Peas in the vegetable garden, as shown at Fig 8: A, rows of Peas; B, one row of Violets. Fig. 9 shows how to put out plants in a border facing the west, a good summer position for them. The large-leaved varieties, such as Princess of Wales, require a space of 18 inches between the rows and 10 inches from plant to plant in the rows. The smaller-leaved varieties may be planted 4 inches closer each way. It is very important that the surface soil be kept moistened at first to get the plants established, and afterwards it should be loosened with the Dutch hoe every week. Water when necessary and feed with nitrate of potash, 1oz. dissolved in three gallons of water, once fortnightly from the middle of June to the end of July. The small runners, as shown in Fig 10, must be pinched off while quite small. Plants treated in this way will be in excellent condition for lifting and planting in frames about September, to provide flowers during the winter months. It is useless putting weak, poorly-grown plants into frames as they can never give really satisfactory results. It is hoped to deal with the work of preparing the soil and transplanting the Violets just before the proper time for doing so. In the meantime every effort should be made, on the lines indicated above, to get as good plants as possible for the purpose.

Varieties.—Princess of Wales, De Parme, Marie Louise, John Kaddenbury, La France and wellsiana are all good. G. G.

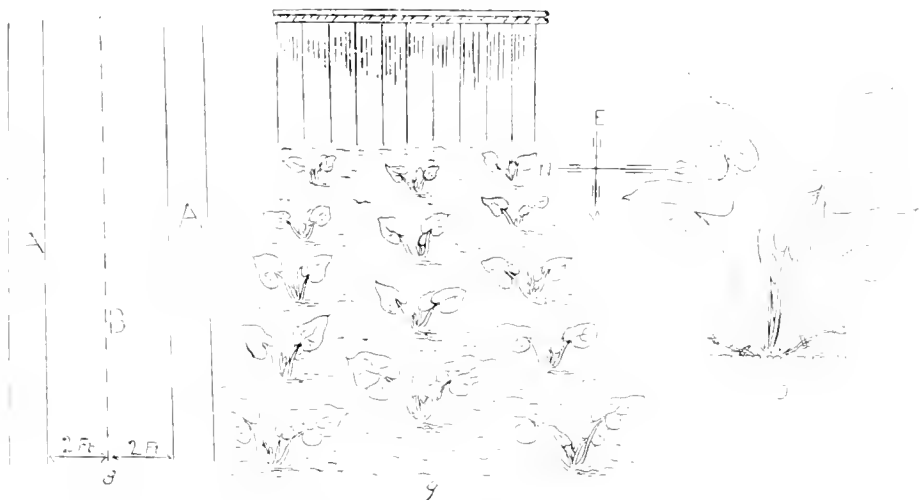

1.—DIAGRAM SHOWING HOW VIOLETS PRODUCE SUCKERS AND RUNNERS WHICH MAY BE USED FOR PROPAGATION.

if the young plants are carefully reared. A Violet plant will grow in almost any kind of soil, but it will not bear many fine flowers if badly treated.

Runners and Suckers.—Both grow from the old or parent plant; but the former are borne on long stems, which spread out over the surface of the soil, and the latter grow up through the soil, in some instances close to the old plant, and many of them grow from the base of the latter. Now, the best of the two kinds is the sucker, because it bears larger flowers and more continuously than the one on the runner. The latter persists in producing more runners, and consequently it does not attain to a large size itself and the flowers are small. The suckers are, therefore, the best, and though they may not be as plentiful as the runners, they should be secured in preference to them. Fig. 1 shows the old or parent plant, Fig. 2 the runner, and Fig. 3 the sucker. The runners may be layered just the same as Strawberries, by pegging them down, or by merely burying the stem and base of the young plant in some prepared compost. The suckers must, however, be more carefully treated. First clear away some of the old soil from around them and the base of the old plant generally. Replace the soil with some sifted leaf-soil, sand and a small quantity of heavier loam, well mixed. Press the new compost fairly firmly round the suckers and keep it in a moist state. In a very short time new roots will have formed, and then the rooted suckers can be detached from the old plants. In cases where the suckers are found growing up through the soil, they must be examined, and

as shown at Fig 5—5. Of course, it is absolutely necessary to cut off these late runners as soon as they are large enough to handle, or they will rob the young plant of much nourishment. The other sketch, Fig. 6, shows the sucker growing with a free centre and producing large flowers. All blooms, however, must be pinched off regularly, as the main object is to get large plants for autumn, winter and spring flowering. The propagation of the plants is the same both in frames and in the open border. Fig. 7 shows a peg for fastening

2.—SHOWING HOW THE YOUNG VIOLETS SHOULD BE PLANTED IN THE OPEN.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Pentstemons.—Young plants propagated from cuttings in the autumn and wintered in cold frames should now be in hardy enough condition to warrant their being planted out in vacant spaces in the borders. Where planted in the herbaceous borders it is best to make a nice clump of from three to a dozen plants.

Antirrhinums raised in the autumn either from seeds or cuttings may be treated in the same manner while seedlings recently raised in heat should be pricked out 2 inches or 3 inches apart in boxes, or in the cold frames from which the others are taken.

Dahlias.—Cuttings should be potted off as soon as nicely rooted, keeping them in a little heat till established, when cooler treatment should be afforded them, potting them on into 4½-inch or 6-inch pots as they require it. This extra potting is quite necessary if good plants and early bloom are required. Early planting out is often fatal, and plants starved in small pots are very slow in getting away after being planted out. Stock plants may be put out in a cold frame where they can have plenty of light and air, with, of course, the necessary protection in case of frost.

Chrysanthemums.—Border varieties, as soon as well rooted in 3-inch pots, should be grown as hardily as possible. On mild nights the lights may be left off altogether, thus preparing them for the planting out, which should be done quite early in May.

Flower-Beds.—Many of the Narcissi planted in the beds will be going out of flower, and the flower-heads should be removed at once. Double Tulips, which are always rather late in opening, may require a stake to prevent them being damaged by wind and rain; but the tie must be loose, or the heads will break off as the flower-stems grow.

Plants Under Glass.

Peppers.—These are excellent pot plants. In fact, many of them make really good decorative subjects for the autumn months, a few good ones being Coral Gem Bouquet, Chameleon, Cerise, Cayenne, Old Red Chilli and Red Cluster; while of the larger varieties that may be mentioned are Ruby King, Chinese Giant, Giant Red, Giant Yellow Noera, Elephant's Trunk, Early Yellow and American Bullnose. Seeds should be sown in heat, potting off singly into pots as soon as large enough to handle and growing on in a heated pit.

Begonia Gloire de Lorraine.—A batch of cuttings should now be put in, and if the pots are plunged in a brisk bottom-heat, rooting should not take long. Cuttings taken quite from the base of the old stools usually make the best plants, though many people rely on leaf-cuttings; but I have not found them so generally reliable as the first mentioned.

Poinsettias.—Rested stools may now be cut fairly hard back and introduced into a warm, moist house to provide a batch of cuttings for striking during May, reserving a portion of the stock for later batches.

Euphorbia jacquiniiflora may also be started soon, but these plants do not care for severe cutting back, and I prefer to leave these about a foot long, when stronger and more easily-rooted cuttings are likely to be obtained.

The Kitchen Garden.

Peas.—If properly hardened off, Peas raised in pots, boxes, or turves should now be planted out, choosing a day when the weather conditions are suitable. The soil should be broken up as finely as possible, thus ensuring the plants getting a good start, and if small stakes are put to them immediately after planting, they will afford a little protection. Dressings of soot also may be necessary to keep away slugs.

Broad Beans.—These also should be planted out at once, and if they have attained a fair height, a small stake and a tie may be required by each plant.

Cauliflowers are rather more tender than Peas and Beans, and a little protection should be provided when planting out. If a fairly deep and broad drill

is taken out and the plants put out in the middle, it will protect them a little. The soil, if pulled in as the plants attain size, will keep them steady; also a small branch of Laurel placed over each plant will protect it in case of sharp frost.

Parsley.—Seedlings raised in a box or frame may now be pricked out in the open ground, and in cold soil such a system is often better than sowing early in the open ground.

Fruits Under Glass.

Tomatoes.—Plants setting their fruit should be fertilised with a rabbit's tail to ensure a good set, this being especially necessary when the house is not entirely devoted to the Tomatoes. In such a case the atmosphere of the house may not be all that is desired. Plants that are fruiting in small pots must not be neglected as regards manure, so that as soon as a truss or two are set it is as well to give a little top-dressing and so keep up the vigour of the plant, or weak trusses will result. Successional batches must be potted on or planted out as they require it, making a sowing during the next week or two to provide a good batch for early autumn fruiting.

Cucumbers that are fruiting also require liberal treatment in respect to manure and water, and where only one or two plants are grown, a little thinning of the fruit may be necessary to regulate the supply. The shoots also may require thinning, and where space is limited may be stopped at every second leaf. As often as roots appear at all thickly on the surface of the soil, top-dress with horse-manure and loam, about half and half.

Hardy Fruit.

Peach Trees on Walls will now have set their fruit—at least, where they have been sufficiently protected—and even now it is wise to allow a double thickness of old fish-netting to hang in front of the trees to protect them from the cold winds. Wherever the leaf blister appears, all the diseased leaves should be picked off and burnt and the trees given a good spraying over with sulphide of potassium at the rate of 1 oz. to three gallons of water. Though this may not actually prove a cure, it may prevent it spreading.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Planting Sweet Peas.—Weather and the condition of the ground permitting, this operation should be carried through at an early date. If not already attended to, the clumps or lines along which the Sweet Peas are to be planted should have a dressing of pigeon or fowl manure, or one of soot and superphosphate, which should be forked in a few days prior to planting. If the plants have been raised in boxes, they should be carefully lifted and planted with a trowel 1 foot apart if the highest results are to be obtained; but for general decorative work 6 inches apart is quite sufficient.

Montbretias in Pots.—Many of the Montbretias are worth more trouble than is often taken with them. We pursue the following system here, with highly satisfactory results: When lifting the bulbs in the autumn the clumps are broken up, generally into halves. We then pot them up into 6-inch pots. They are wintered in a cold frame, and about the middle of March are stood outside in some sheltered spot. About this date they are planted, with the bulbs intact, either in masses or lines.

Sweet Violets.—Runners—rooted if possible—should now be taken from the plants in frames and planted 1 foot apart in a plot which has been specially prepared for them. Violets require liberal cultivation, with cool conditions.

Plants Under Glass.

Cannas.—If started in small pots last month, these will now be ready for a shift, and as they are vigorous growers, they may at once be transferred to their flowering pots. Cannas delight in a rather porous, rich soil, and as they have fleshy roots, they should be potted rather loosely.

Stopping Chrysanthemums.—All the classes of Chrysanthemums require stopping more or less. Stopping in the big-flowered section has been reduced to a fine art and cannot be dealt with in a small space. Those who have not learned the art should study the directions given in such a price-list as that of Messrs. Wells, Limited, Merstham. Bush plants should be stopped when about 6 inches high, stopping the freer-growing varieties again when the plants have made about another six inches of growth.

Strobilanthes dyerianus.—To see this fine foliage plant to advantage it must be grown liberally in a brisk temperature, and as its bright colouring fades with age, successional batches of cuttings should be struck.

Fruits Under Glass.

Peaches.—The tying in of the shoots must be attended to as growth advances. The young shoots can often be tied alongside the older bare ones; but in any case they should be as evenly distributed as possible, special care being taken to fully expose to the light the succession shoots at the bases of the bearing ones.

Figs.—In early houses where the fruit is swelling, the temperature should be raised somewhat, the atmospheric moisture being increased in proportion. As the fruit begins to ripen, however, the air should be kept in a drier condition.

Melons.—If any of the plants show signs of canker at the neck, the affected part should have a little dry powdered lime or powdered charcoal applied to it. If, however, the plants were slightly raised above the general level at planting-time and ventilation has been carefully attended to, there is seldom any trouble with canker.

The Hardy Fruit Garden.

Grafts.—If the weather continues dry, grafts should be examined; and if found to be too dry, a little damp moss should be tied round them and sprayed every few days till growth takes place or rain occurs.

Loganberries.—This useful fruit is now throwing up young shoots freely, and all superfluous ones should be thinned out. The number to be left must be determined by the amount of space to be covered.

The Shrubbery.

Evergreens may still be planted, but the work should be completed as soon as possible. If dry conditions obtain, the newly-planted stock ought to be watered at the roots and be sprayed overhead in the afternoon.

The Pleasure Grounds.

Amelanchier canadensis.—The Snowy Mespilus is one of our most floriferous and most beautiful ornamental trees, and deserves to be more widely cultivated. Its only defect is its slowness of growth. It does best in bush form or as a standard grafted on the common Hawthorn.

The Kitchen Garden.

Kidney Beans.—A sowing of an early variety, such as Ne Plus Ultra, should now be made on a south border in rows 21 inches apart, with 6 inches between the seeds. If the seeds are steeped in tepid water for twelve hours previous to sowing, germination will be accelerated.

Asparagus.—The beds should have a dressing of rotted manure forked into them. Seed may now be sown and plantations made. The latter operation must be carried through with great care, as the plants suffer very much if the roots are exposed to the air for any length of time.

Beetroot.—This useful vegetable may be sown during the next week on ground that has been deeply worked and has had no rank manure applied to it. The drills should be about eighteen inches apart. There are many varieties to choose from, but I can thoroughly recommend Goldie's Exhibition and Frisby's Excelsior.

Spring-Sown Onions.—Those raised under glass may now be planted out according to the directions given last week for the autumn-sown crop. Of course, where extra large bulbs are desired, ample space must be allowed for their development, a square foot not being too much for each bulb.

Broad Beans.—Another planting should now be got in for autumn supply.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mans, Midlothian.

THE FIFTY BEST ALPINES. NEW AND RARE PLANTS.

THE lists of choice alpine which appeared in THE GARDEN for March 1 and March 15, from Mr. Arnott and Mr. Farrer, have been exceedingly interesting to all lovers of these choice little gems. Although I have nothing like the extensive experience of your two well-known and able correspondents, yet "fools will enter where angels fear to tread," and at the risk of being classed among the former I now enclose a list of what I consider to be the best fifty. In this list are included several commoner sorts which seem to be ignored by the more experienced growers; but although common and easily grown, they are none the less beautiful. The Gold Dust (*Alyssum saxatile compactum*) and the Crimson Thyme (*Thymus Serpyllum coccineum*) are both unique in their respective colours, which, when seen in a mass, are perfectly dazzling in the sunshine.

I found curtailing the list to fifty a more difficult matter than extending it to one hundred would have been, many beautiful and useful plants having had to be eliminated. This difficulty would have been considerably increased if shrubby plants and bulbs had been included. Perhaps at a future date lists of both of these beautiful and indispensable plants for rockeries might be given [Yes.—Ed.], as I have no doubt such would prove as interesting and helpful as the lists of alpine have been.

Name.	Height. Inches.	Aspect.	Soil.	Colour.	Flowering Period.	Means of Propagation.
<i>Achillea argentea</i>	4	Sunny	Loam	White	Summer	Division

<i>Vittadendia trilobata</i>	5	Sun	White and rose	March to October

Ochilview, Bridge of Earn.

AWARDS OF MERIT.

Douglasia laevigata.—A pretty and rare plant from the Alps of Oregon, closely allied to *Androsace*. The entire plant is not more than 1½ inches high, of close-tufted habit, after the manner of a free-growing *Androsace carnea*, above which the rosy red flowers appear in clusters. The certificated example was shown in a pot 5 inches in diameter, which it nearly filled. Few of the hardy plant specialists had seen this gem in such condition before. From Mr. Reginald Prichard, West Moors, Wimborne, Dorset.

Carnation Mrs. Wilfred Gott.—A pure white-flowering variety belonging to the Perpetual-flowering Malmaison section, and an acquisition to boot. Plants in pots were shown demonstrating great freedom of flowering and an entire absence of calyx splitting. The plants, although growing in small pots, showed exceptional vigour, the stiff, erect stems carrying the handsome flowers without support. One of the best attributes of the new-comer is its powerful Clove-like fragrance, a quality which cannot fail to make it popular with all. From Messrs. William Cutbush and Sons, Highgate, N.

Primula viscosa Othello.—A beautiful and showy variety, said to have resulted from the crossing of *Auricula Innocence* and a selected variety of *Primula viscosa*. Except for the increased vigour of the above, there is no external evidence of the influence of such a cross, the best

attributes of the *Primula* being seen in an enhanced degree. The colour is rosy red and very effective. The plant is very free-flowering.

Primula viscosa Jean Douglas.—This charming alpine *Primula* resulted from the crossing of *P. viscosa* and *P. intermedia*. The colour is a warm rosy tint, the trusses, like those of the first named, large and abundantly flowered. These were shown by Mr. J. Douglas, Great Bookham, Surrey.

Narcissus White Emperor.—We regard this as an unfortunate name applied to a flower of sterling merit. In the first place, it is not an Emperor in any sense, though the name might suggest that it was either a seedling or white sport from that well-known highly-popular sort. In short, it is superior in many ways to Emperor, more particularly in the fine overlapping character of the perianth segments and in their firm texture. This fine white *Narcissus* is of distinguished bearing. See illustration on page 184. Shown by Messrs. Cartwright and Goodwin, Kidderminster, and Mr. Christopher Bourne, Bletchley, who, we understand, are sharing the stock of this handsome novelty.

NEW ORCHIDS.

A number of novelties, some of them of exceptional value, were brought before the Orchid committee. No fewer than five first-class certificates were granted. *Cymbidium Humblotii*, shown by Messrs. Charlesworth and Co., secured this high award, with a cultural commendation in addition. Other novelties to gain first-class certificates were: *Brasso-Cattleya heatonensis* Canary and *Cypripedium Roundhead*, both shown by Lieutenant Colonel Sir George Holford; *Odontoglossum eximium* Warnham Court, from C. J. Lucas, Esq., Horsham; and *Laelo-Cattleya dominiana* Southfield variety, from Waters Butler, Esq.

Awards of Merit.—*Cattleya intertexta Juliettae*, shown by Firmin Lambaun, Brussels; *Odontioda Cooksonæ* Ralli's variety, from Pantia Ralli, Esq., Ashted Park; and *Odontioda keighleyensis ignifera*, shown by Messrs. J and A. McBean.

The foregoing awards were made by the Royal Horticultural Society on April 1, when all of the novelties were shown.

THE FRUIT GARDEN.

MEALY BUG ON PEACHES.

THE mealy bug often causes a lot of trouble among the Peaches about this time. Fumigation may be resorted to, but unless it is constantly repeated the new broods hatching out seem to establish an ever-increasing army difficult to overcome. Should only an odd insect or two be noticed, the simplest method is to touch the bug with a drop of methylated spirit at the end of a stick—an old-fashioned and effective remedy. If in large numbers, however, I strongly recommend syringing with an insecticide once a week. This must be done regularly, and as syringing is always being carried out, very little extra work and trouble is entailed by the process. I have tried many insecticide washes, and the following has proved the best, most effective and cheapest: Take one gallon of warm rain-water and into it measure a teaspoonful of paraffin and a like quantity of soft soap (the disinfectant soft soaps now sold are by far the best for making

WILLIAM LITTLE.

up horticultural washes, and they are just a trifle clearer than the ordinary soaps). Churn the mixture to get a thorough emulsion. To assist this, draw it up in the syringe and squirt it back into the pail a few times. Keep stirring it all through the process of spraying, in case the oil separates out. Larger quantities are made up in proportion. The wash should be about the same temperature as the Peach-house before spraying.

Syringe the tree from various directions to get at all parts. Apply in the afternoon, and then syringe again with tepid water the following morning. This remedy is most effective, does no harm to the trees, and tends to keep down all other pests as well.

Chryston.

HUGH H. AITKEN

PRICKING OFF SEEDLINGS OF ALPINE FLOWERS.

THE raising of seedlings of alpine flowers is pleasant and interesting work which may well be recommended to the amateur who desires to secure a stock of such plants at a moderate cost. Many plants of good alpines can be obtained from seeds with but little trouble, although some time is required for pricking off the seedlings. This should be performed at the earliest suitable time, as in this way strong, healthy plants can be secured.

It is always desirable to prick off the seedlings as soon as they have made a pair of their second or true leaves, even though the plants are then very small. A compost of fibrous loam, leaf-soil and sand in about equal proportions will answer well, although any good garden earth or loam lightened with leaf-soil and sand will answer well. Clean pots or pans can be employed, but boxes will do quite well if they have plenty of holes bored in them and a sufficient depth of drainage put in the bottom. These boxes require about the same depth of drainage as pots, and about a third of the depth of the box or pot filled with drainage is not too much. Over the drainage put some of the rougher compost; then fill up to within about half an inch of the top, and press the compost gently but firmly down with a piece of wood.

The seedlings ought to be carefully lifted out of the seed-pot so as to injure the rootlets as little as possible, and to avoid disturbing the seedlings which are not large enough to prick off. If the seedlings are very small, a piece of wood, like a pointed match, may be employed to lift out the young plants and to make a hole for planting them in the box or pot to which they are being transferred. When the seedlings are inserted, they should be put in to the base of the first leaves, and the soil gently firmed about them. When the whole have been removed, the box should be thoroughly watered with a fine rose, the plants kept rather close for a day or two, and then gradually be given air.

If the whole of the seedlings are turned out of the pot and the soil thrown away, much loss will result, as there are frequently many seeds which have not germinated, but which will do so later, many even appearing the following spring. This is especially the case with such things as Primulas, Gentians and many others. Early pricking off, careful handling of the seedlings, thorough drainage of the pots or boxes in which they are placed, and proper after-attention in the way of giving air and water will be well repaid by securing a number of healthy plants.

AN OLD ALPINIST.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering plants, where possible, should be fresh. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

VIOLETS (Mrs. F. F.).—The appearance of the Violet leaves suggests that all is not quite right with the drainage, and that the ventilation has not been as free as it should have been at times during the past particularly mild and damp winter.

PERGOLA PATH (A. H. E.).—The least expensive path would be one of gravel, or the burnt ball-ast common to many country places. The gravel may possibly bind well; the other will not, at least alone. Bricks or tiles would require to be set in mortar, or they would move about. Clean screened cinder-ashes mixed with lime or cement would be as cheap as anything, and employed in this way would not prove unsightly. Borders of Mossy Saxifrage, say, *S. hypnoides* variety, or white garden Pink would do quite well. Both are of easy culture and inexpensive, and while costing little for the upkeep, would prove effective for some time.

ROCK GARDENING (B. M. B.).—A book likely to be of service to you is "Rock and Water Gardens," by the late F. W. Meyer, published at 6s. net at the office of this paper. Independently of this, or even in conjunction therewith, you might study the valuable series of articles entitled "Rock Gardens in the Making," which, commencing in the issue of THE GARDEN for October 26, 1912, were continued weekly to the end of that year. This series deals with many phases of the work. If, however, you are contemplating building a rock garden, and have but little knowledge of the subject, your better plan would be to confer with a specialist on the spot. The position appears to be in some respects favourable, assuming it is not so near the sea as to suffer from the ill-effects of the salt spray.

INCREASING LEUCOPHYTA BROWNII (H. O.).—We have made enquiries and cannot find that seed of *Leucophyta (Cabecephalus) Brownii* is obtainable. The general method of increase is by means of cuttings, which are not at all difficult to root. They should be taken off at a length of a couple of inches or thereabouts, and be dibbled into prepared pots of fine sandy compost. After this they need to be placed in a close propagating-case, and if there is a slight bottom-heat, so much the better. If the case is too close—that is to say, if there is an excess of atmospheric moisture—the cuttings are liable to damp off. In the summer cuttings may be struck in an ordinary garden frame without any artificial heat, provided the frame is kept close and shaded from direct sunshine until the cuttings are rooted.

IRISES FOR RIVER BANK (M. J. C.).—There are no Irises more suitable for the purpose than those known as Flages, and these, while crowning the top of the bank, might overflow down the bank itself. If you desire a bold display at the top, we would suggest that you employ only one variety, viz., *pallida*, and arrange for a yard-wide band of it. If you desire more than one variety, we suggest *Queen of May*, *Alme*, *Chereau*, *Cracibus*, *Dr. Berner* and *Mrs. C. Darwin* to make a distinct set. Down the bank the common purple *Flage* and *Princess of Wales*, white, would do perfectly. You might plant at once, giving all a fair start in deep-dug soil. We presume the bank soil is not infested by wireworms, which are partial to these Irises. You might establish Daffodils in plenty on the bankside by planting bulbs in autumn. Scarlet Dogwood, Flowering Currant, *Berberis Darwinii*, *Spiraea*, *Bentzia* and *Wiegela* in variety are shrubs that would prove useful for the purpose. The Irises and Daffodils, with Dogwood for winter effect, would, we think, produce the best result.

PRIMULAS AND AURICULAS (J. H. P.).—We need not advise Auriculas, as you already do them so well, but the following Primulas, in addition to those enumerated by you, should succeed under the conditions named: *P. bulleyana*, *P. capitata*, *P. cockburniana*, *P. denticulata*, *P. d. alba*, *P. floribunda*, *P. Forbesii*, *P. involuta*, *P. rosea*, *P. Sieboldii* in variety, *P. viscosa*, *P. v. nivalis*, *P. v. Mrs. H. J. Wilson* and *P. Veitchii*. We have at one time or another met with a dozen forms of double Primrose, but cannot say whether they are all in existence now. In a catalogue of one of the principal hardy plant nurseries we note eleven varieties mentioned

It gives us great pleasure to learn that you have been so successful with your Auriculas, more especially as you have gained your information from THE GARDEN. It has always been our aim to assist our numerous readers, as far as possible, and the many grateful letters that we receive show that our endeavours have been largely crowned with success. We trust that your display of Auriculas will in every way come up to, or even exceed, anticipation.

PLANTS FOR HIGH, DRY WALL (M. M. C.).—If the wall is quite dry and no soil exists between the stones, you will have difficulty in establishing plants therein. If, however, you can introduce a little soil into the crevices, such things as *Aubrietias*, *Alyssum saxatile*, *Zauschneria californica*, *Iberis sempervirens*, *Erinus alpinus*, *Snaydragons*, *Thrift*, *Iceland Poppies* and *Centranthus ruber* may be grown. The whole of these may be introduced by means of seeds, mixing a pinch of seed with a pint of moist soil and working it into the crevices. If this quantity of soil was distributed over a 2-foot run of the wall, a group would be presently formed; or perhaps you may like your wall to be a mass of *Aubrietia* in May and June, and if so, the entire wall may be treated with varieties of these plants, which afford sheets of colour in pink, violet and lilac. The best plants for the paved walk would be *Campnulus pusilla* and *alba*, *pulla* and *mirabilis*, *Meothis Requinii*, *Arenaria balearica*, *Ernus alpinus*, *Linaria pilosa*, *Thymus Serpyllum coccineum* and *Sedum hispanicum glaucum*, all of which, save *Ernus*, should be introduced by means of small pieces of plants into the crevices between the stones. The present is a good time to plant.

FAILURES IN SWEET PEAS (H. H.).—In the first place, we advise you not to plant your Sweet Peas in a deep trench which has been partly filled with well-rotted manure, though certainly the ground should be well trenched all over, and where the rows are to come there may be a slight depression, just sufficient to allow the moisture to run towards the rows rather than away, this more for economy when applying water artificially; but if your ground is heavy, plant or sow quite on the flat. We have only come across one lot of Sweet Peas that acted in the same manner as yours—grow quite well and failed to open or throw many bloom-buds—and this was also on a rather low and damp position. Earlier in the season we should have advised you to have given the soil a thorough good liming all over, and even now, if the plants or seeds are in the ground, you might give the ground a fair sprinkling of fresh-slaked lime, taking care not to get too much of it on the young foliage. This may prove all that is necessary. Instead of the lime, or in addition to it, you might give the rows a dressing of superphosphate of lime and sulphate of potash, say, 1oz. of each to each yard run. This may be given two or three times during the growing season at intervals of two or three weeks.

THE GREENHOUSE.

INJURY TO BEGONIAS (Begonia).—You should always send specimens when asking for advice, for that enables us to be more certain of the cause of the trouble enquired about. There are two causes for the so-called "rust" in *Begonias*—redworm and mite. Probably the latter is at work in your plants; but it is very difficult to see without a powerful lens. We think you will find (if the mite is the source of the trouble) that dipping the plants now and then in a wash made by kneading flowers of sulphur into a handful of soft soap and dissolving it in one and a-half gallons of warm water will be the best remedy.

DAFFODILS FAILING (P.).—It is difficult to give a reason for the comparative failure of some of your Daffodils, but one thing struck us. Although you say they were treated on the lines laid down by the Rev. J. Jacob in his book, you mention they have been in the Auricula-house throughout. Now, the Rev. J. Jacob in his book advises them, when potted, to be plunged under Cocoanut fibre refuse or ashes outside till they are well rooted. If you overlooked this, it might be answerable for your very limited success. Again, success or otherwise will depend upon the vigour and condition of the bulbs, as if they contain but a single flower in embryo, a solitary bloom is all that one will have, however they may be treated. We should advise you to water the bulbs until they die down naturally, and then plant them out next August or September.

GREENHOUSE FLOWERS FOR CUTTING (D. C.).—Wallflowers sown now, afterwards planted out, and in the autumn lifted and carefully repotted will flower well in the greenhouse. The *Antirrhinum*, *Dianthus* and *Campanula pyramidalis* should be sown in July and August. Two good varieties for the purpose are *March* and *Queen Victoria*. Other subjects that can be recommended for flowering in such a structure are *Forget-me-not*, sown now and potted up in the autumn, while *Lardy Primrose* are also satisfactory if carefully lifted and potted. Seeds of *Primula sinensis*, *P. kewensis* and *P. obconica* may be sown now, and *Stocks* *Beauty of Nice* and *East Lothian* in May. Besides these, some of the late-flowering *Chrysanthemums* are very valuable in the greenhouse. These can, as young plants, be purchased at a cheap rate now. Bulbs, too, are worthy of consideration, though the bulk of them do not flower till the new year is one or two months old. *Roman Hyacinths* potted in August will, however, flower by Christmas, while *Crocuses* will, under glass, anticipate by some time their usual season of flowering out of doors.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Finsbury Street, Covent Garden, W.C.

NOTES OF THE WEEK.

The Mezereons. The varieties of *Daphne Mezereum* are flowering exceedingly well this spring, so that the popular idea that the want of ripening caused by the wet summer would prevent them blooming so freely has not been borne out by facts. Rarely, if ever, have we seen bushes so full of bloom as this spring, and some of them are literally laden with flowers. Curiously enough, they are flowering later than usual.

Wallflower Early Paris.—This useful plant is undoubtedly one of the most valuable of Wallflowers, owing to the long period it may be had in bloom. By sowing seeds now, flowers may be had from the end of the summer on through the autumn and winter—providing they are planted in a warm, sheltered spot and the weather mild—till the spring, when they are followed by the Wallflowers that are usually grown, giving us this favourite flower most of the year. The Early Paris type can be had in yellow and brown shades, and seed is cheap.

Fasciated Stock.—At a recent meeting of the scientific committee of the Royal Horticultural Society, Mr. H. Stuart Thompson sent from Carquieranne, South of France, part of a fasciated example of *Matthiola sinuata* bearing hundreds of flowers and having a stem about two and three-quarter inches in width. Though fasciated plants are very frequently shown before the committee—perhaps more frequently than those showing any other aberration of growth—Stocks have rarely or never been exhibited in this condition. The present specimen was growing on the cliff outside an hotel garden, and others there showed a similar habit of growth.

Newly-Planted Fruit Trees.—In many districts, owing to the very wet and sticky condition of the soil, the planting of fruit trees could not be carried out in such a satisfactory manner as when the earth is more friable. Now that it is becoming drier, cracks of various sizes will probably appear, which must be immediately filled, and it will be expedient to see that the soil is quite firm around the base of the trees. The wind has also been very rough in most parts of the country, and it behoves the grower to see that his trees are secure, especially where any staking has been done, for it sometimes happens that the tying material or stake is chafing against the tree, which will cause irreparable damage unless given prompt attention.

Tulips in Grass.—As far as we can gather, there seems to be great doubt if Tulips will continue to bloom more than one or two years when they are planted in grass. The bulbs will go on living, and year by year they will send up a large single leaf, as much as to say, "I am here all right, but no bloom this year." Our contributor the

Rev. J. Jacob is most anxious to gather reliable information about their behaviour from those who have grown them in this way. A wider knowledge of this important branch of Tulip culture is much wanted. We heartily endorse Mr. Jacob's appeal and hope he will have many communications on the subject, so that later on in the year he may be able to place before our readers some reliable facts. His address is Whitwell Rectory, Whitechurch, Salop.

Primula japonica as a Water-side Plant.

People who are only familiar with this species when it is grown as a single specimen or as a small group can have no idea of its imposing character when cultivated on an extensive scale, as is sometimes practised in gardens in the South-West Counties, and particularly at Enys, near Falmouth. In the latter garden it is naturalised in the vicinity of the lake, and covers a considerable area of ground, the plants being particularly vigorous, the leaves large, the inflorescences tall and strong, and the colour of the flowers rich. There is no necessity to introduce fresh stock at any time, for an abundant supply of self-sown seedlings appear. It is, however, necessary to weed out the poor-coloured forms each year, for by this means only can the best strain be kept.

A Simple Cure for Black Spot in Roses.—In the National Rose Society's Annual, fuller particulars of which appear elsewhere, Dr. Arthur R. Waddell gives some most interesting and instructive information on the treatment of black spot, a fungus that attacks the foliage of Roses very badly in some districts. Dr. Waddell has proved that commercial formaldehyde (40 per cent.), one tablespoonful to a gallon of water, is an excellent preventive. This should be sprayed on to the plants and also the soil at frequent intervals during the growing season. Dr. Waddell has also found it answer well for mildew and Rose black mildew. This commercial formaldehyde can be obtained cheaply and is clean to use. Rose-growers will, in future, be able to successfully combat the pests mentioned above.

The Chatham Island Forget-me-not.—Although suggestive of an ordinary Forget-me-not, *Myosotidium mobile* belongs to a different family. Writing in the *Lyttleton Times* of May 2, 1909, Dr. Cockayne describes it fully, and mentions two other but less appropriate common names which are sometimes used, viz., Chatham Island Lily and Macquarie Cabbage. Under natural conditions the plant is said to be almost extinct, though at one time it formed a continuous belt along the seashore just above high-water mark. In those countries where it thrives it is certainly a plant which ought to be widely grown. It would not, however, be wise, in the face of its being well known to be suitable only for certain localities, to make an extensive planting without previously testing its ability to withstand the climatic conditions of the district.

CORRESPONDENCE.

The Editor is not responsible for the opinions expressed by correspondents.

Annual Saxifrages.—In THE GARDEN of April 5 your correspondent H. E. Molyneux, referring to *Saxifraga cymbalaria*, writes: "I believe the only annual member of this large family." Our delicate little native *S. tridactylites* is another.—G. G. T., *Stratford-on-Avon, N.B.*

Platystemon californicus and Its Common Name.—In your issue of April 5, page 171, in an article containing a reference to *Platystemon californicus*, the writer queries the existence of a more common name for this interesting plant. There is one, and he is not far from the mark in suggesting Cream. The garden name is Cream Cups. I think that is correct.—H. A. DAY, *Eltham, Kent*

A Beautiful Colour Combination.—Your note of this in THE GARDEN for March 29, page 153, encourages me to make mention of a similar lovely combine I took notice of last year. The discovery came more by chance than by set purpose. At

pinnate leaves keep fresh and bright, and furnish a delightful setting for the rich red flowers, which appear in large terminal inflorescences. Each flower is from 2 inches to 3 inches long and curiously shaped, the shape having suggested the common name of Parrot's Bill Plant, which is current in New Zealand. *C. puniceus* is not a difficult plant to grow, but it requires frequent renewal, for after giving good results for several years it begins to deteriorate, and should then be replaced by a young specimen. There is a white-flowered variety, but it is less showy than the type.—W. D.

Snow in Norfolk.—Norwich and Norfolk experienced the full force of the snowfall on the 11th inst., quite 5 inches falling, and with a strong wind much damage was done to the spring flowers. The Narcissus family seems to have fared worst. Generally speaking, the blooms of these were at their best, but the weight of the snow brought them down to the soil and utterly ruined thousands. On the morning of the 12th a frost followed, but, previous to this, much damage had been done to the Plum blossom by cutting winds, which had shrivelled tender subjects as if they had been burned.—AVRON PEA

Seasonable Advice.—In our intensive methods of modern cultivation we have come to recognise that diseases and plant pests are making great headway against us, and that every precaution ought to be taken to eliminate all chances of bringing fresh troubles into our gardens. I have conducted many experiments in connection with this matter and made a large number of investigations, and I want to warn readers that every fresh plant which is brought into the garden should be sterilised or disinfected. To do this, liver of sulphur solution (1oz. per two gallons), Bordeaux mixture, Quassia solution churned up with soft soap, or some of the valuable proprietary insecticides and fungicides advertised in these columns should be employed, and new plants sprayed from top to bottom. Only by such methods can one expect to preserve a garden pure and free of pests, and the plan is thoroughly efficient if consistently practised, besides being well worth the trouble. A garden free of pests and diseases is a "thing of beauty and a joy for ever," and greatly to be desired in these days of advancing horticultural science.—HUGH H. AITKEN.

Saxifraga Grisebachii.—From the note in your issue for March 8, page 120, I was surprised to learn that this Rockfoil does not thrive so well as could be wished for in England. This is a great pity, for the species is really of exceeding beauty when it grows away freely. Maybe the difficulty is confined to some localities with exceptional climatic conditions. The report from a place where the plant gives no cause for complaint may be welcome, and perhaps show the way to success. I have a plant on my rockery which forms a firm, close cushion, having at the present time thirty rosettes, sixteen of which bear flower-spikes. For this plant a hole 8 inches deep by 4 inches wide was cut in the top of a block of hard tufa rock, and a small channel to drain off water was driven in laterally to the bottom of that hole. This receptacle was then filled in with calcareous, gritty, loamy soil, with a little peat, into which pieces of sharp-edged limestone of Walnut size were closely pressed, the whole being firmly pressed down as the work went on. When the top was reached, the plant—then a simple rosette—was inserted a little above top-level. In course of time, through the action of rain and waterings, some soil was washed away from the neck of the rosette, so as to leave it a little raised up, the method of planting resembling, in fact, that recommended for planting *Androsace helvetica*. The plant has now occupied this place for five years, always looking healthy, and it has since increased to the size above mentioned. The aspect is south-west, a position which few species of the encrusted section could stand unscathed; but neither the scorching sun of 1911 nor the unceasing rains of last season harmed it. The illustration shows four alpine pots, some with one, others with originally two or three single rosettes, the latter having now grown together into one compact tuft each. These plants have a little more soil, and the rosettes are of great size, some measuring 2 inches across. These plants are now four years old, and are bearing twelve, sixteen, eighteen and twenty inflorescences respectively. I have increased this Saxifrage considerably during the last five years without any difficulty. I will not close this note without a word in favour of another lovely species, *S. thessalica*, not quite so imposing, but sweetly pretty with its more modest little purple spikes.—E. HEINRICH, *Planegg, near Munich, Bavaria.*

WELL-GROWN PLANTS OF SAXIFRAGA GRISEBACHII IN BAVARIA.

the top of a small rockery were a few plants of *Linum perenne*, while immediately below a few bare places existed. To hide these latter some plants of the Ivy-leaved *Geranium Mme. Crousse* were obtained and planted. When they both came into flower, the effect was really splendid; the light pink trusses crouching at the feet of the graceful swaying blue spikes at once arrested the attention. It has since occurred to me that the arrangement of these two plants would make a striking summer bed. The Ivy-leaved *Geranium* would be trained over the bed to make a groundwork, and the *Linum* used as a dot or upright plant at intervals.—C. TURNER, 3, *Kenwood Road, Highgate, N.*

The Parrot's Bill Plant.—No more beautiful wall plant than this, *Chanthus puniceus*, can be found for planting in Devonshire, Cornwall and other places with a similar climate, for from mid-March to early June it blossoms with great freedom, the flowers being of a peculiarly showy character. A native of New Zealand, it has long been in cultivation, and is a favourite plant for growing on greenhouse rafters and pillars in many parts of the country, but in such positions it can rarely be allowed to develop so freely as is the case when it is planted against outside walls. Its evergreen,

The Scarlet Windflower Failing.—Mr. S. Arnott's desire, on page 181, April 12 issue, to discover the cause of failure of this lovely subject is welcome. In the home of my childhood it flourished year after year in ordinary perennial beds, receiving, so far as I know, no special treatment. The soil was shallow, on limestone rocks with perfect drainage, and in the same mixed beds I remember great mats of *Daphne Genkwa*. Alas! now both are gone. In another garden for a number of years several beds of *Anemone fulgens* flowered regularly with the greatest profusion. The position was high, 600 feet above sea-level. The beds were on the top of a sloping bank which falls rapidly towards the west. The soil was a light, gravelly loam, with limestone rock just below. The tubers were planted deeply and never moved, and in the summer the surface was used for bedding plants; yet for many years they continued to be a perfect success, vigorous, increasing, a mass of blooms, until a new gardener with new methods soon settled them. I have had success with first season new tubers, but failure afterwards, although a few isolated clumps that are neglected and in apparently unsuitable places never fail to bloom well.—ERNEST BALLARD, *Colwall near Malvern.*

DAFFODIL NOTES.

SOME OF THE RECENT GEMS AT VINCENT SQUARE.

BEFORE I carry out my promise of last week, a word or two of explanation is necessary. Top-of-the-tree varieties, such as *Cresus* and *Bernardino*, are too well known to need a description here. I have only one card trick.

I get a bystander to draw a card, and after he has looked at it I ask him to put it back anywhere in the pack, which I give him for the purpose. I then take it back, and having given the cards a real good shuffle, say: "You are quite sure you know the card?" "Yes." "Quite certain?" "Yes." "Oh! then there is no need for me to tell you." There is no need for me to describe flowers already familiar to my readers. So will they please note these twenty are not the very best of all that were there. These best-known ones and the brand-new unnamed seedlings, with two exceptions, are on this occasion passed by on the other side. Here, then, is my list, alphabetically arranged, and with the exhibitors' names in parentheses directly after the name of the flower.

Ambell (Watts).—A pretty, almost white Ajax. The perianth is of the double triangle type, with overlapping segments, and of a greenish white colour. The trumpet is primrose. Size, 3½ inches by 1½ inches by 1½ inches.

Anette (R. Sydenham, Limited).—A "Crosneld" Giant Leedsii. No crossfield flowers are anything but very good—none, at any rate, that the public ever see. He is a very "Spartan" among his seedlings. The perianth is flat and overlapping, and the cup primrose, well formed and prettily frilled. Size, 3½ inches by 1½ inches by 1½ inches.

Bloodstone (Barr).—About the nicest flower on the stand. The cup has a very distinct angular appearance, and the orange red edge looks as if it was the top of a ruffle. The perianth is white, slightly ribbed and rather undulating.

Bride of Lammermoor (Barr).—A distinct white trumpet, with a perianth shaped like that of Sir Francis Drake. Its weak spot from a show point is the top of the trumpet, which has an ungainly look. It is, however, a striking flower, and one that many people will like.

Fire King (R. H. Bath).—An improved Lucifer. The red in the cup is of a deeper shade, and the perianth not so floppy. Mr. Leak tells me that the sun only intensifies the colour, and before it is over it looks as if you would burn your fingers if you touched it. This is just what we all want.

Gold Coin (R. Sydenham).—A taking and very distinct bloom, a five-pound piece running away, with broad white streamers all round it. Size of diameter of reflexed perianth, 2½ inches; of the eye, 1½ inches.

Impressario (Chapman), but Chapman's no longer, as it was bought by that most exacting critic "P. D." It is a soft Nelson yellow trumpet, with a smooth, overlapping and very slightly hooded perianth. The trumpet has a very refined look, and is broadly flanged at the apex. Size, 4 inches by 1½ inches by 1½ inches. A beautiful show bloom.

John o' Gaunt (Cartwright and Goodwin).—A magnificent large yellow trumpet raised by Mr. Chapman. Mr. Engleheart told me he had tried to buy it; but, like Pierpont Morgan with Hardy's

manuscript, he had tided. Later in the afternoon I met Mr. Tom Page of Hampton looking very pleased with himself and wearing a fine bloom of *Carnation Mary Allwood* in his button-hole. I soon found out why—he was the purchaser. His market instincts led him to single out this particular variety as something in his line which he was prepared to pay for. It is a flower of the star-shaped type, with broad, overlapping perianth segments, with a slight twist in the three alternate ones. Size, 5½ inches by 1½ inches by 2 inches. Very fine indeed.

Lissadell 238-9 (Lissadell).—A beautiful pale canary triandrus seedling with quite an incomparable look, so much so that those unfamiliar with Daffodils might easily have thought it some relation to *Homespun*. Size, 3½ inches by seven-eighths of an inch by 7/8 inch. It was one of the most distinct flowers in the show, and so delicate and refined.

March White (R. H. Bath).—A very early-flowering, almost white Ajax of moderate size. Perianth segments slightly twisted, trumpet pale primrose. The plant is vigorous and tree-flowering, and the flowers are borne on long stems. It has the makings of a very fine pot variety; but that will not be yet awhile, as the price is about four to five pounds.

Paulhan (Chapman).—A delightfully clean and pretty-looking Barri with a pure white perianth and a cup of clear lemon edged with an orange red. It first showed its face, as the old flower books would say, when the celebrated aviator was trying to beat the London and North Western express from London to Manchester; hence its name. Diameter of the whole, 3 inches; of the eye, three-quarters of an inch.

Pixie (Wilson).—A show flower in every sense of the word. Smooth and refined; large, spreading eye, with a red edge graduating in shade to the yellow centre. Perianth ivory white and much overlapping.

Pluckley (Warren).—A refined yellow trumpet. One of the Westbere seedlings, and having the good texture and substance of that celebrated strain. Size, 4 inches by 1½ inches by 1½ inches.

Queen of the North (Barr).—An improved and enlarged White Lady. Bound to be a popular flower.

Red Lady (Bourne).—If one put an *Almira* perianth on to a *Firebrand* cup, slightly enlarged, one would have something like Red Lady. I fancy it wants good cultivation, but, given that, it is a charming thing. Size, 3½ inches by seven-eighths of an inch.

Sarabande (Bath).—A Chapman Poet with a medium-sized red eye and a striking *Poetarum*-looking perianth. A good-sized flower. Size, 3½ inches by three-quarters of an inch.

Sardius (Wilson).—A fine bit of colour. The deeply-edged eye at once arrests attention, and in combination with the slightly-reflexed and long-segmented perianth gives us a most pleasing bloom. Size, 3½ inches by 1½ inches.

White Emperor (Bourne and Cartwright and Goodwin).—A dividing (see last week's notes) and a divided (in ownership) flower. If it had only been named *White Empress* I would have called it divine. Size, 4½ inches by 1½ inches by 1½ inches. Undoubtedly an exhibition flower of a very high quality; but it does not seem to me to be either fish, flesh, fowl, or good red herring. It has too much of a Leedsii look if one thinks of it as a

FORTHCOMING EVENTS.

April 22.—Midland Daffodil Society's Show at Birmingham (two days). Lincolnshire Daffodil Society's Show.

April 23.—Royal Horticultural Society's Examination in Cottage and Allotment Gardening. North of England Horticultural Society's Spring Show at Leeds.

April 24.—Norwich Spring Flower Show.

April 26.—Ghent Quinquennial Exhibition (nine days).

Calceolaria Veitchii.—As a supplement to the article on *Calceolaria alba* on page 157, March 29 issue, attention may well be directed to a delightful hybrid from it, namely, *Calceolaria Veitchii*. This, which was given an award of merit at the International Exhibition last May, was raised at the nursery of Messrs. Robert Veitch and Son of Exeter, the parents being *C. alba* and an albino form of that pretty garden variety *Golden Glory*, which was also raised at Exeter and is now much grown. A prominent characteristic of *C. Veitchii* is its extreme vigour, in which respect it greatly surpasses either of its parents, as it forms quite a neat bush from 3 feet to 5 feet in height and bears a great profusion of milk white flowers, with, when first expanded, a slight yellowish tinge. The foliage is, except in size, somewhat after the manner of *C. alba*, as the leaves are lanceolate in shape and much serrated. It comes readily from seed, and the young plants grow away freely. Besides this, it may also be struck from cuttings. Another variety shown at the "International" by the same exhibitors was *Bronze Age*, a plant 18 inches to 2 feet in height, of a loose, pleasing habit of growth, and bearing good-sized flowers of a rich bronzy crimson colour. Both are good decorative subjects for the greenhouse.—H. P.

How to Grow Saxifraga burseriana.—Beginners in the art of growing alpine plants have many difficulties to contend with, but the difficulties are increased when those who offer instruction as to the method of treating the plants differ among themselves. Take, by way of example, *Saxifraga burseriana*. Mr. Reginald Farrer, in "The Rock Garden," page 68, says "This (*S. burseriana*) detests sunshine and open positions," &c.; yet in his other work, "My Rock Garden," he classifies *S. burseriana* among the *Kabschia Saxifragas*, which, as he states on page 115, require light, limy loam, and an open but not too sunburnt exposure. Compared with one another, most people would say that these two statements are contradictory. Having tried *S. burseriana* and its varieties *Gloria* and *Magna* in a partially-shaded position, with the result that I obtained one bloom from the three plants, I sought out other authorities. On consulting Robinson's "Alpine Flowers for Gardens," I find "it soon forms good-sized tufts, preferring a dry, sunny situation." On my appealing for advice to Mr. Clarence Elliott, who has exhibited magnificent examples of *S. burseriana Gloria* at recent Royal Horticultural Society's shows, he wrote me that I should give a south or south-west aspect. Now will some of your readers who have had more experience than I have had be good enough to vouchsafe information on the subject? He would be a bold man who would suggest that Mr. Farrer has made a mistake in the advice he has given in "The Rock Garden," but it looks like it. Would Mr. Farrer also be good enough to say which he really thinks is the correct method of growing this (to me) difficult plant?—ALPINIST.

trumpet, and too much of a trumpet look if one thinks of it as a Giant Leedsii.

White Pennant (Bath).—The greatest novelty in the Hall. A Giant Leedsii of exquisite substance and with long, almond-shaped perianth segments very slightly incurving. The cup is well formed, of pale primrose colour, with a decidedly deeper shade on its broadly-flanged edge. Here is a proportion sum worked out: As The Doctor is to The Earl, or, say, Frank Miles to Autocrat, so is White Pennant to Empire.

Wilson's 500 (Wilson).—A "cool customer." It has a very green-looking centre, with the narrowest of red edges and a slightly undulating white perianth. Size, $3\frac{1}{2}$ inches by five-eighths of an inch. It might be said by some to be a little lacking in colour, as the red is not very pronounced. To me, however, it appealed very much. JOSEPH JACOB.

PLANTING A PAVED GARDEN.

I FIND the best tool to use in planting a stone pathway in a rock garden is a small wooden dibble and the handle of an old tooth brush, as the spaces do not permit of the more orthodox instrument. On that portion of the path which receives the most wear I find *Arenaria balearica* is invaluable, running like a green film in the V-shaped grooves between the stones, and spreading on to the upper surface of the pavement whenever the tread permits of it. Other good plants are *Arenaria caespitosa*, *Cotula squarida* and *acutifolia*, *Epilobium nummularifolium*, *Linaria equitribloba*, *Thymus Serpyllum* and, last but not least, that charming little close-growing Mint, *Mentha Requienii*, from Corsica.

In the bays formed by a projecting rockery, where the tread is slight, *Linaria alpina*, *Campanula pusilla* and *C. pusilla alba* scramble about very prettily, while, where it can partly rise up against the face of an upright rockery stone, *Antennaria tomentosa* and *A. dioica* variety *rosea* make a silvery patch. If the path is sufficiently wide, and not too frequently walked over, many other plants may be introduced, such as many of the medium-sized *Campanulas*, like *C. pulla*, *C. pulloides*, *G. F. Wilson*, *Stansheldii* and even *carpatica*, also *Sedums*, such as *S. reflexum*, *S. rupestris* and *S. pulchellum*, where they will not be caught by the foot. It is best, however, to start with the fairly rapid and dwarf growing plants, and considerable attention should be given in the early days to replacing any pieces which may get disturbed either by the foot or by some inquisitive sparrow, since in such a position the plants have not the same opportunity of undisturbed extension which they get in a sheltered bed in the rock garden.

REGINALD A. MALBY

THE GREENHOUSE.

THE PERPETUAL-FLOWERING CARNATION IN SCOTLAND.

THE production of plants of Perpetual-flowering Carnations is pursued on different lines in Scotland to those in the South of England, though the flowering treatment is identical, or practically so. Individual methods, no doubt, vary; but unless some of the chief practical points are similar, success may be diminished even to the vanishing-point. Like

warm all the winter up to the end of March. It has never raised the temperature, which was seldom higher than 50°, and frequently as low as 45°; but the slight heat seems to be beneficial in the way of opening the blooms, and no doubt it allows for ventilation in cold weather being given without any ill effects.

But of even more importance than a proper structure in which to flower the plants is one in which to grow them during the summer months. I have been very fortunate in having a low pit originally erected for border Carnations, &c., the sides of which can be opened wholly by means of wooden shutters, which, when closed, form the sides. A portion of this has been fitted with top ventilators, so that the plants in the hottest weather may be as cool as if they were in the open, where, it may be explained, they will not succeed so far North. Throughout it is imperative that they be grown all along under glass. I am sure that quite a number of cultivators fail during the summer through lack of facilities to give the plants the treatment they demand—protection from the weather and unlimited ventilation.

Propagation.—About the propagation of Carnations there is much diversity of opinion, and this surely demonstrates the adaptability of the plant when it is found to propagate so easily in so many diverse ways and at various dates. I have found the cuttings to root equally satisfactorily dibbled into sand in boxes, in the sand bed of a propagating-pit, and in small pots. In pots there is the advantage of being able to remove those which are first rooted without disturbing those not so forward, or, what is worse, to leave the first rooted till the others are ready, which weakens the former, for it is clear that until roots are produced, top growth is at a standstill; but once roots are formed it becomes active, and is one of the evidences of root production. I like to take the cuttings early in October. It is said that there is no advantage in striking the cuttings so early, but I cannot escape noticing that those who delay operations for two months or more fail to get as many breaks as do those who propagate early. Nor do I care to have the plants stopped too soon. Apparently time should be gained by early stopping, but unless the plant is very strong and well established, the breaks will be as four to six or eight

THE NEW PERPETUAL-FLOWERING MALMAISON CARNATION MRS. WILFRED GOTT.

others, I have had to feel my way and adapt methods to means and circumstances.

I bloomed a portion of the stock very well last winter along with *Chrysanthemums*, and when the structure was required for Arums, the Carnations were transferred to a cool Peach-house, where they have continued eminently healthy, but have yielded fewer good blooms. I think, on the whole, that a structure devoted solely to the plants will always give the greatest satisfaction. In the little span-roofed house set apart for them here, the heating pipes have been kept slightly

on an average of the strong plants. Then the impression that it is essential to break off cuttings with a heel is not borne out in practice. A healthy and stout cutting roots just as freely when cut off as if pulled off, and the former has the advantage of producing a sturdier plant with strong shoots from the very base. I have plants growing from pieces cut off the base of the cuttings which were inserted with only two leaves; but these need not be used unless to get up a stock of a particular variety, as, of course, they never make large plants. Stopping, it may be added, cannot be safely done after the beginning of June.

The Best-Sized Pots.—I am sure that it is a mistake to limit the pots to 6-inch ones. Continuity of bloom requires a pot of 7 inches or 8 inches diameter, though in the case of weakly-growing sorts the smaller size may be admissible. Those who can command a strong loam ought to be grateful, because in a rooting medium of this kind blooms of the finest quality can be produced; but those whose soil is of a light nature need not despair. The blooms at their best will not be so fine, and it will be necessary to feed the plants from an early stage of growth either with such a manure as Bentley's Carnation Manure or with soot-water, which is excellent. Under suitable conditions disease will be a negligible quantity, and of the insect tribe the only member that ever attempts to colonise is the aphid. I have heard of thrips and red spider affecting plants, but so far North the conditions do not seem to suit them. To sterilise a small quantity of soil, Wulfing's Formalin is excellent. It should be applied at least a week previous to the soil being required. To conclude, do not expect fine blooms from weakly shoots; but remove these, however heartrending the process may prove, and those left will feel all the better for their absence. R. P. BROTHURSTON.

A NEW PERPETUAL-FLOWERING MALMAISON CARNATION.

The new Carnation Mrs. Wilfred Gott, which recently gained an award of merit from the Royal Horticultural Society, combines the good qualities of the Perpetual-flowering and the Malmaison Carnations. The handsome pure white flowers possess a powerful clove-like fragrance. The broad grey recurving foliage and the large globose flower-buds closely resemble those of the true Malmaison, but the plants showed the exceptional vigour and freedom that is characteristic of the Perpetual-flowering varieties.

ROCK AND WATER GARDEN.

A PRIMROSE FOR THE WATER-SIDE.

(PRIMULA ROSEA.)

THIS beautiful Himalayan Primrose, which gladdens us with its umbels of intensely rich carmine flowers during March, is an indispensable waterside plant, in addition to making itself almost equally at home in rather drier situations, provided vegetable soil enters largely into the composition of its rooting medium. During the winter months it forms deep bronzy red, resting buds, which at the first call of spring open and expose the cluster of blossoms neatly packed in their centres. Given reasonable weather conditions, these buds develop with surprising rapidity, and while the blossoms frequently open when but 1 inch or 2 inches above the ground, the flower-stem finally reaches a height of 6 inches or 8 inches, and sometimes more. Even here in the smoke-laden air of Woodford this Primula appears to be of the easiest culture, while it comes so readily from seed that no gardener should be without it. When the crowns become numerous, it is advisable to break them up, replanting some few inches apart. Not infrequently the resting buds have a tendency to rise out of the soil, and this should be counteracted by either gently pressing them back into the ground or—perhaps the better way—placing some top-dressing about them. REGINALD A. MALBY.

THE NYMPHEAS OR HARDY WATER LILIES.

(Continued from page 182.)

Methods of Planting.—Various methods of planting can be adopted, but the system I have practised from the very first I have found to answer well. To begin at the beginning, in our case here, I would state that the first order that was given was for a dozen varieties. That would be about eighteen years ago. The cost of all of these did not amount to £3; but I should state that the plants were all small, though well rooted and healthy. When unpacked on arrival from M. B. Latour-Marhae I placed them securely in shallow Strawberry punnets. These held them quite comfortably, each plant being tied in to prevent its escape by any movement of the soil. These, with the exception of *N. flava*, all thrived well the first

the bottom of the basket, then some broken up turfy loam and road scrapings. Into this soil the plants were timidly placed, being again tied down to prevent floating. That season the eleven plants grew surprisingly well, and flowered quite freely for their size.

Dividing the Plants.—In about three years afterwards I found it necessary to divide the stronger-growing varieties. These were *N. Martinea albida*, *N. M. chromatella*, *N. M. rosea* and *N. M. carnea*, all of which are well known as vigorous growers, even under adverse circumstances. I then used larger nursery rounds of from 3 feet to 4 feet in diameter. It was somewhat of a difficulty to lift the plants that time, so well had they rooted into the muddy bottom of the lake. They were slid back into the water; then, by means of a cord, the baskets were pulled into greater depth from the other side. Divisions of these and other

AN EFFECTIVE GROUPING OF PRIMULA ROSEA, A CHARMING SPECIES FOR THE ROCK GARDEN OR WATER-SIDE.

season and survived the following winter, which was a very severe one. The plant of *N. flava*, however, succumbed during that trying winter. As I did not then feel assured of their hardihood, I covered the ice, soon after it formed, with some straw litter, to prevent, if possible, a thick coating over the Lilies. I followed this system of protection for a few seasons afterwards. Finding, or at least deeming, it not to be essential, I ceased to cover them, and have never done so since. These little plants of the first season grew so well, and a few flowers were the result in the second year from planting. At two years from their receipt I lifted them carefully. The punnets were, as a matter of course, decayed, but the roots all lifted well. I then transferred the plants to small, but old, nursery rounds of about two feet in diameter. The soil I used then—and I have found nothing to answer better—was, first, a layer of decayed leaves over

strong-growing varieties have taken place since. One has to be careful, I find, about the division of the weaker growers. This has to be done with more care and not so frequently. I divided our plants of *N. odorata rosacea* and others of this section, and they never thrived well afterwards, I am sorry to say. The root growths of these are much smaller and not nearly so succulent or sappy, being somewhat hard in texture. They make much smaller roots in comparison also. The *N. Laydekeri* section appear to be somewhat intermediate in growth, but they grow freely, all the same, and flower most profusely, but, like the *N. odorata* section, do not need to be disturbed so frequently.

Never on any account should tubs be used. This is an utter mistake, for the soil in them becomes stagnant and sour beyond any hope of improvement. I have heard of Teak tubs being used for

the purpose, but it is an expenditure that cannot be in any sense justified. Wire baskets are not so bad as tubs, because aeration of the water and the soil can then take place within them. But wire baskets will contract, or limit, the growth of the rhizomes, and this is to be regretted. Loose bricks are better than wire baskets, as these can be removed and extended. Of all the systems, however, I much prefer nursery rounds, without any handles to them. In small and easily accessible fountains, or basins of water, I consider nothing to equal bricks of the usual size; these should be built up lightly and loosely, so as to hold the soil. About three courses of these are sufficient for all but the strongest growers, and these only need four courses at the most. So-called "pockets," or hollow spaces provided in rockwork, at times are bad places for Water Lilies, as the soil cannot be readily renewed in them.

Season of Planting and Seedlings.—After several years' experience now, I find no time to equal the spring. From the last week in April

THE KITCHEN GARDEN.

SEASONABLE NOTES ON VEGETABLES.

Tomatoes for Outdoors.—In these days we expect to see Tomatoes growing splendidly in the garden of the cottage as well as in the ornate establishment attached to a nobleman's home. It is, in a sense, extraordinary how popular they have become, because they are not the easiest of plants to manage, and when outdoor culture is the only method possible, disappointment is apt to come, despite all efforts to guard against or prevent it. To ensure success the season must be a sunny one, but the grower should always endeavour to produce such excellent plants that the utmost advantage will be secured of the good weather that comes along. To this end the plants now in 2½-inch pots should be transferred to those 1½ inches in diameter when the present pots are full of roots, while those in boxes must go into 3-inch pots preparatory to passing to the larger

but it is so welcome on the table that no cultivator hesitates to accept the slight risk involved in sowing after the middle of this month. Choose a variety like Sutton's Crimson Globe, drop seeds in groups of three at intervals of 20 inches, and thin out, always reserving the weakest plant, provided it is healthy, as it will produce the most refined root.

Scarlet Runners.—The season when this plant becomes most useful is very late in the summer and autumn, when the Green Peas have either gone for the year or are scarce, and sowing in May meets the demand. It is, however, almost invariably necessary to have pods ready for picking much earlier in case they are wanted, and seeds should therefore be sown under glass at once to provide early plants. Do not attempt to rush them in a high temperature, as this spells weakness and involves trouble when they have to be planted, but grow sturdily and strongly to secure hardy plants. No matter how carefully they have been managed, they must have a process of hardening prior to planting in deep, rich soil in the position chosen. Sow out of doors twice, or even thrice, between the first week and the end of May.

Dwarf French Beans.—Amateurs and cottagers commonly fail with these delicious Beans for two reasons. One, they will sow too early; and two, they will grow too thickly. The plant is exceedingly tender, and must not be sown until May, or the youngsters will be yellowed, and it is quite possible they will never recover. Then they are of strong, branching habit, and should always be 15 inches, and better 18 inches, asunder in rows 3 feet apart if they are to develop their full capacity for fruiting. H. J.

POLYANTHUSES AS STREAMSIDE FLOWERS AT CLANDON PARK.

to the third week in May I consider to be the best time to both plant and divide the rhizomes. The water then is more perceptibly rising in temperature week by week, and this will be congenial to quicker root development. Later planting may be safely practised, but such does not give the plants the same opportunity of re-establishing themselves before the autumn sets in. I should never attempt to plant or divide after August draws to a close. If by any chance seedlings are noted during the summer months, it is better to mark these and leave them until the following spring before in any way attempting removal. If during the month of August or early September any seed should be seen floating upon the surface of the water, it may be secured and at once sown in mud, then raised in a temperate house. After the bursting of the seed-pods the seeds only float twenty-four hours, then sink to the bottom.

JAMES HUDSON, V.M.H.
Tramshbury House Gardens, Acton
(To be continued.)

size just mentioned. Always use a compost of loam, leaf-mould and sand, and if there are wood-ashes at command, add some.

Maincrop Carrots.—These ought to be sown this month, and those who labour on an unkind soil and desire to produce the 3-foot, perfectly straight, even roots which gladden the eye at shows must bore for them. Make holes 3 feet or more in depth, according to the variety, fill with light, open compost, sow three seeds in the top, and thin to one plant in due course. Most of us, however, do not aspire to such heights as this, but are contented with medium-sized roots of fine quality. We therefore prepare a quarter that was well manured for the previous crop by deep digging, and every effort is made to ensure friability. Then drills are drawn 1 foot asunder, and at intervals of from 4 inches to 8 inches groups of three seeds are dropped, to be reduced to one plant when it can easily be seen which is the best.

Beetroots.—This is one of the tender salad vegetables which are best sown in bulk in May,

are good in any garden use, but best of all where they may have a place to themselves, as in some quiet space of woodland, such as is the natural home of the wild Primrose. This is especially the case with the large yellow and white Bunch Primroses, which, in such a place, can be used in bold massings. The finest effect is obtained where the woodland adjoins the garden and the Primrose place is reached through a planting of dark-leaved shrubs, such as Box, Yew and Portugal Laurel; and the path, a little winding, suddenly discloses the garden of Primroses, with an effect that is little short of astonishing.

These fine things are not at their best till the third week of April, or, in late seasons, till the earlier days of May, when their effect is all the better for the near trees being in thin, early leaf. The coloured Primroses are better fitted for general garden use, and are all the more valuable if carefully sorted for tints that harmonise together, thus forming a number of separate groups.

FLOWER GARDEN.

PRIMROSES AND POLYANTHUSES.

THERE is no need to extol the merits of these beautiful spring flowers, though it may be helpful to point out which are the more beautiful ways of employing them. They

Within the last fifty years we have come to look upon the dear, homely Primrose as a national emblem of deep significance to a now immense band of patriotic people, and in memory (for it was his chosen flower) of the statesman who conceived the idea and raised the structure of Empire for Britain. It stands to us as the sign of the constant labour and the united effort, all over the land, of those who hold to the best traditions and the noblest interests of our home country and its closely-linked Overseas Dominions. Among those who from the beginning have given untiring labour to the truly national and patriotic work of the Primrose League, it is only fitting to name, in all reverence and honour, the late Lady Dorothy Nevill; and all the more fitting in these pages because of her whole-hearted sympathy with all the best interests and developments of horticulture. Greatly as Lady Dorothy is regretted among her numerous circle of friends, her gracious and cheery presence had become one of the bright features of the fortnightly meetings of the Royal Horticultural Society, from which it can be ill-spared and will be sorely missed. G. I.

SOME GOOD TULIP SPECIES.

Nowadays, when countless seedling Tulips have been raised—early-flowering, medium and late—it must be admitted that the brilliant self colours and mixed hues in almost endless diversity are most effective in beds and borders, while a great advance has been made in the past decade in the Cottage and Darwin sections. Showy, however, as are many of these named varieties, the true species are at least as fascinating, and the flower-loving amateur who once takes up the culture of the latter is not likely to regret his enterprise. The following are handsome species, well worthy of extended cultivation, and have flowered well for the past few years:

Tulipa clusiana.—This was described and illustrated on page 171, April 5 issue, and need not again be referred to in detail.

T. kaufmanniana holds a foremost position among the many rare and beautiful species of Tulip. It is certainly one of the handsomest of the early-flowering species. Its broad petals reflex considerably, and the flowers often attain a diameter of 5 inches. In colour the blossom is creamy white, while the base is golden orange, this being sometimes barred with carmine-red. The buds are tinted externally with crimson. It grows to a height of about a foot, and is a very

early bloomer, this year flowering in February. It is a native of Central Asia, and was introduced in 1877. The open flowers have been likened to those of a Water Lily. In its variety aurea the ground colour is golden yellow.

T. Batalinii.—This is a beautiful dwarf species from Asia Minor, and is an excellent plant for a choice nook in the rock garden. It has long, tapering leaves, and the flowers, the petals of which are pointed, are of a beautiful soft pale yellow, and are deliciously fragrant. Its blooms are about three inches long, and the plants flower in March and April. It is one of the daintiest of Tulips

the plants often opening early in February. The blossoms are faint rose in colour, with a base of deep golden yellow in the interior. The flower-stems are about eight inches in height, and the blooms are about three inches long. One drawback to it is that it is sometimes a shy flowerer.

T. gesneriana is the best known of the Tulip species, and is largely grown in gardens. It is very hardy and does not require annual lifting, as do most of the species, but succeeds well if left in the ground year after year. Its form major is a very fine flower of large size, and a bed of this in full bloom is a gorgeous sight. The colour of the blossoms is a glowing crimson.

T. flava is a noble Tulip and one of the latest to flower. It often attains a height of close upon 3 feet, and has stout stems and leaves. The blossoms are about five inches in length, with pointed, slightly reflexing petals of a clear yellow colour. It is one of the finest of the Tulip species, very strong and free in growth, and of the easiest possible culture. Towering above its fellows, with the sun shining on its bright flowers, it presents a lovely picture.

T. Greigii.—This is a native of Turkestan, and is one of the most gorgeous of all Tulips. Its large, goblet-shaped flowers are brilliant scarlet, and there is no Tulip that can excel it in vivid colouring. Its broad, glaucous leaves are irregularly striped and spotted with purple, which gives it a distinct character. In a garden when twenty or more blossoms are expanded simultaneously the effect is superb.

T. celsiana, also known as *T. anstralis*, is a native of Persia. The flowers, which are yellow, tinged with red on the outside, droop before they expand. The plants bloom in May, and frequent meadows in the chalky mountains at an elevation of nearly seven thousand feet. The species is, apparently, closely allied to *T. sylvestris*.

T. elegans is a very handsome Tulip. The growth is strong and the flower of the richest crimson, while it is even larger than the showy *T. Greigii*. The petals of the flower narrow to a point. It is supposed to be a natural hybrid between *T. acuminata* and *T. suaveolens*, but, if so, is decidedly superior to either parent. In the variety *alba* the petals are white, with a narrow margin of crimson.

T. ixioides.—This is held to be a form of *T. gesneriana*. Its blossoms are of a soft canary yellow, and in the interior is a deep black base, which is very effective and renders the flower distinct from others of its class with yellow blooms. It grows to a height of about two feet.

A BEAUTIFUL GROUP OF THE WATER-LILY TULIP (TULIPA KAUFMANNIANA).

T. tubergeniana.—This was found on the high mountains of Central Bokhara about ten years ago; it is without doubt one of the finest Tulips yet introduced, and has flowered splendidly. Its immense cup-shaped blossoms are of intense scarlet, and often measure as much as 6 inches across. At the base of the petals there is a black blotch. The flower-stem is erect and tall, and the glaucous leaves are of great size. It is very robust, perfectly hardy and does well in English gardens.

T. saxatilis.—This, a native of Crete, is a charming Tulip, and the earliest of its race to bloom,

T. kolpakowskiana.—This is a native of Turkestan and a very handsome species, flowering in April and May. It is one of the most variable in colouring, hardly two bulbs producing blossoms of the same tint. The flowers are often yellow flushed with scarlet, some are pure scarlet, and the charming blending of hues in a large group is very attractive. The plant has lanceolate leaves from 5 inches to 1 foot in length, and the flower-buds are pointed.

T. linifolia is a very pretty Tulip, with narrow leaves and flowers of an intensely dazzling scarlet, which are furnished with pointed petals. The flowers are very lovely and second to none in brilliance.

T. strangulata maculata has soft primrose yellow flowers with a conspicuous black centre. There are two other forms of *T. strangulata*, namely, *primulina*, a soft primrose yellow without the black blotch, and *picta*, primrose yellow, shaded with rose on the outside of the petals.

T. ostrowskiana, a native of Turkestan, is a graceful plant attaining a height of 18 inches. The leaves are narrow, and the flowers, which are each about five inches in diameter, are of a brilliant scarlet.

WYNDHAM FITZHERBERT.

FRUIT GARDEN.

METHODS OF COMBATING WOUND FUNGI ON FRUIT TREES.

IN a previous article (page 100, issue February 22) reference was made to the alarming increase in the prevalence and virulence of the attacks of wound fungi on fruit trees, and the necessity of protecting all the wounds which can possibly be protected was insisted upon. In this article it is proposed to treat with another aspect of the subject, viz., the possibility of feeding the trees so as to render the sap in leaf and in the wood toxic to the fungi. One of the first facts that strikes a thinking person when considering the question of fungus growths on all sorts of vegetation is that, broadly speaking, each fungus confines its attacks to the one particular host plant. When one considers the enormous quantity of fungus spores produced this becomes all the more marvellous, since it is absolutely certain that many spores fall on quite different races to that to which the particular host plant belongs. It must necessarily follow that there is some resistant quality in the sap of these different races of plants which prevents the fungus spore from growing to any degree, and, on the other hand, there must be some affinity between the fungus and its particular host plant. There is not only this phenomenon, but another, even more strange, which can be often observed. In a set of plants, one more sturdy and vigorous than the rest, but not necessarily coarse and overgrown, will be found to be quite free from disease, while all the rest may be attacked. Again,

it is quite clear that thousands of spores must fall upon this plant from its affected neighbours, and the natural inference is that there is something in the sap of such a plant which is inimical to the growth of the fungus spores.

Such phenomena as these suggest a possible method of dealing with fungus attacks, which has certainly some element of hopefulness in it. Unfortunately, very little is at present known concerning the substances which can be introduced into the sap of plants which will not be harmful to them, and in addition will be toxic to fungi.

One or two facts closely related to the manuring of plants are, however, pretty well established. In the first place, a very luxuriant growth caused

silver-leaf disease, which attacks Plums and Apples, with little or no result. Some experimenters, however, claim to have succeeded by the use of superphosphate. The writer has not himself seen these experiments, but he has it on very good authority, and the results are described as very good indeed, plantations being quite cleared of this nasty disease. It is believed that the best time to sow the superphosphate is in the late summer or early autumn, August or September, before the leaves fall from the trees, and the quantity required would not exceed 5cwt. per acre; but the best quality, giving the highest percentage of soluble phosphates, should be used.

Several additional experiments are now in progress to endeavour to prove the truth or otherwise of the conclusions previously arrived at; but the results cannot be ascertained till the foliage of the trees comes out this spring-time and summer, when it is hoped definite information will be secured whether this treatment really effects a cure for silver-leaf. Another substance which has been tested for silver leaf, but which has up to the present given very varying results, is sulphate of iron. It is to be supposed that the first experimenters, knowing that it had a good fungicidal action, endeavoured to get it taken up in the sap of the trees for the purpose of dealing with the fungus, whose mycelium is in the inside of the tree, in the wood and bast cells. For this purpose the well-known practice, so often advised for combating silver-leaf, of boring into the main stem of the tree and inserting finely-ground sulphate of iron, was proposed. As stated above, however, the results obtained have been very diverse, some experimenters claiming to have quite cured the affected trees, while others could see no good results following the process. It is extremely important that careful experiments should be made to endeavour to discover a method by means of which the active fungicidal properties of the sulphate could be rendered assimilable by the tree sap, and so be conveyed all over the tree to act as an active agent in checking the germination of any chance

THE EARLY-FLOWERING TULIPA SAXATILIS, NATIVE OF CRETE.

by heavy dressings of nitrogenous manures unbalanced by phosphates and potash almost invariably falls a prey to any fungus disease to which its race is subject. For example, the worst attack of *Cladosporium fulvum* (the Tomato rust) to be found in the greenhouse is generally on the plants most highly fed with nitrogenous manures; and, again, fruit-growers are finding to their bitter cost that the dreaded American Gooseberry mildew is invariably worse where the manure has been most liberally supplied. On the other hand, to take only the case of the Tomatoes, plants supplied with a sufficiency of potash are noticeably much more free from disease.

Unfortunately, at present it has not been found that potash has much beneficial effect in checking disease in fruit trees. It has been tried for the

spores which may fall upon leaf or branch, and also to resist the advances and growth of any disease which may be present.

Another method of using the sulphate of iron for combating the various fungoid diseases is to sow it round the base of the trees, forking it into the soil, the idea being to get it taken up into the tree by the medium of the roots when in solution in the soil water. As before, this method seems to have met in some cases with but scant success, while in others it seems to have accomplished a great improvement in the trees affected. At present the superphosphate manuring seems to be the most successful method, as well as the simplest, in dealing with these wound diseases, and it is in this direction we turn most hopefully in our battle with these insidious foes.

F. W. HAMMOND.

GARDENING FOR BEGINNERS.

THE CULTIVATION OF ANNUAL POPPIES.

AS each April comes round, my thoughts turn unerringly to the summer show of Shirley Poppies that brighten the garden in delightful art shades of colour. Surely no flowers could be more easily grown—a handful of seed scattered over a prepared plot of ground, and very little attention is required. There are just one or two salient points, however, to bear in mind. Seedling Poppies never transplant well, and in consequence the seed should be sown in the places where the plants are to flower. It is a common mistake to sow the seeds as thickly as Mustard and Cress, with the result that the plants are weak and spindly and the flowers of poor quality. To sow thinly and to thin early are both of the utmost importance, and it is a good plan to mix the fine seed with sand, and then to sow both sand and seed together. By this means an even distribution of seed will be ensured. Before sowing, the seed-bed should be well prepared. The soil should be forked over and the surface left fairly firm and even after being raked over. The seedlings should eventually be thinned out to 6 inches or 8 inches apart, so that side shoots may develop and carry flowers.

Not only are Shirley Poppies so valuable for colour effect in the garden, but they are welcome as cut flowers for table decoration. When used for this purpose, however, the flowers should be cut in the bud state and allowed to open indoors, when they are found to last much longer than if cut when fully expanded. Flower-buds cut in the evening and placed in water indoors will be found wide open the next morning, to the astonishment of those who are unaware of this quality.

The Shirley Poppy is an admirable subject for the sunny garden and for semi-wild places or open woodland, such as that depicted in the accompanying illustration. The same may be said of *Papaver Rhæas*, the common Corn Poppy, of which the Shirley Poppy is but one of its many cultivated forms. The Opium Poppy, *Papaver somniferum*, and its varieties require the same treatment as that advised for the Shirley Poppies. SPARTAN.

THREE BEAUTIFUL ANNUALS.

The three beautiful half-hardy annuals, *Phlox Drummondii*, *Browallia elata* and the double-flowered *Zinnia*, are very effective in the flower garden when the plants are well grown.

Phlox Drummondii has many charming colours. During the past ten years the improvement in the strains has been most marked. The plants in these days are more compact in habit and may be used entirely for filling flower-borders. They

soon grow to the flowering stage, and continue to bear blossoms until the end of October, or when frost comes in November. A good compost must be used in which to raise the seedlings, and when the latter are large enough to handle, prick them out 3 inches apart in a light compost in boxes, and still retain them in a warm frame. From the boxes transplant them in a cool frame or one temporarily constructed. If the young plants are grown under cool conditions during April and the early part of May, they will be in fine condition for the flower garden at the end of May. The following colours may be obtained: Pink, crimson, rose, scarlet, white,

way and carefully hardening them during the fortnight or so prior to planting in the flower-beds they will soon become established and fill the beds, flowering freely. Small, puny specimens are rarely satisfactory.

Zinnias.—Unless the single-flowered varieties find special favour, I strongly recommend cultivators to grow the double-flowered. The latter, when well grown, are really splendid for bedding-out purposes. *Zinnia elegans grandiflora robusta plenissima* is a charming variety. The foliage is so robust, a good point, as very often the foliage of *Zinnias* is sparse and the plants present a ragged appearance. Slugs are partial to these plants while

SHIRLEY POPPIES IN AN OPEN WOODLAND SPACE.

marbled, rose with white eye; purple, white eye; white, dark eye; scarlet, white eye; and blue, white eye.

Browallia elata.—This is an exceedingly beautiful annual, and should be grown in all flower gardens. The plants are generally grown and flowered in a greenhouse, but will do equally well in the flower garden if planted there the first week in June. The plants attain a height of about eighteen inches, and bear white, blue and violet blue flowers respectively. Sow the seeds thinly in boxes or pans, and place the latter in a warm frame or on a greenhouse shelf. Transplant the resultant seedlings in boxes at a distance of 2 inches apart, and still retain them under glass. It is very important that the seedlings be nursed in a genial atmosphere during their early stages, and when taken from the greenhouse they should have the shelter of a frame until the early part of May. By building up fine bushy plants in this

in the seedling stage, and I have often found that where young plants have been attacked, they rarely recover normal conditions. Raise the seedlings in a temperature of about 65° and continue to grow them in a warm place, but guard them from slugs. The soil for the seedlings must be rich, but not containing any fresh organic manure. The manure must be rotted and passed through a half-inch mesh sieve, so that the particles will mix with the soil. In such a compost the roots will cling to the manure when the plants are put out finally. Prepare the flower-bed in a similar manner, and when the plants are growing freely in it give a few waterings of weak, clear soft-water; then both leaves and flowers will assume a richer colour. The plants grow about eighteen inches high. Sow the seeds without delay. There are about eight distinct colours, including Fire King, scarlet, and Queen Victoria, pure white, with flowers 4 inches or more across. AVON.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Pleasure Grounds.

Mowing.—With the warm weather the grass will be growing freely, and to keep it in good order a weekly mowing will be necessary. If left a fortnight the bottom will be found to be turning yellow, especially where the grass is very thick, and if a sharp frost occurs immediately after mowing, it will look bad for three or four weeks.

Sowing Grass Seed.—If necessary, bare patches may still be sown with seed; in fact, the seed germinates much quicker and better now than at any time, though it is wise to try to choose a time when the wind is not too drying.

Gravelling.—Any gravelling that has to be done should be proceeded with at once, breaking up the old gravel with picks or forks according to the nature of the surface, levelling this over nicely before proceeding to lay the new gravel. Too heavy a dressing is quite as bad as too little; in the latter case the rough stones soon show through the surface, while in the former case it is apt to be soft and spongy during wet weather. It seems unnecessary to add that it should be rolled well before being walked upon, following this up with a thoroughly good rolling in after the first heavy rain.

The Rose Garden.

The Beds.—Now that all the pruning is done, the beds should be carefully edged and the surface soil pricked over with a fork, making it as fine as possible in the operation—this to facilitate hoeing, which should be done regularly from now onwards.

Spraying.—Before the buds get too far advanced it is advisable to give all the plants a good spraying with paraffin emulsion, this acting as a preventive to both mildew and green fly. Some may prefer other insecticides or fungicides, but this does not matter, the point being to prevent rather than to cure these enemies, and by making an early start there is a much better chance of getting the upper hand.

Plants Under Glass.

Humea elegans.—This fine decorative plant is now throwing up its flower-head, and should be fed regularly with liquid manure. Artificial, if given, must be in very small quantities, or a loss of foliage may result; the roots, being very fine, are easily injured by an excess of water or manure. Seed should now be sown for next season's plants, using a shallow pan and fine soil for sowing, while an intermediate temperature will suit them best until such time as the seedlings are large enough to prick off.

Zonal Pelargoniums, rooted in February in 3-inch pots, should now be advanced enough for potting on into 4-inch or 4½-inch pots, adding a little bone-meal to the compost when potting. Pinch out the point of each plant when nicely rooted in the larger pots, and so induce a bushy habit of growth.

Caladiums, being nicely rooted, may be potted into the pots in which they are to remain during the summer, this being desirable before they become at all potbound. A very light mixture of fairly lumpy peat, leaf-soil, loam and sand, with a little charcoal added, suits them well. Plenty of heat is necessary if good large and well-coloured leaves are desired, and if the water is at all likely to discolour or form a sediment on the foliage, the plants should not be syringed overhead, but a good moist atmosphere must be maintained by spraying between the pots, while shading is necessary during bright sunshine.

Sweet Peas in Pots.—These will now be taking an almost unlimited supply of water during bright weather, and on no account must they be allowed to suffer. As soon as the first blooms commence to open, liquid and artificial manures may be given frequently, but these must be kept in abeyance till the buds are very forward, or they are apt to drop; also too high a temperature must be guarded against.

The Vegetable Garden.

Salsify.—This deep-rooting vegetable may now be sown, selecting a piece of ground that has been deeply dug or trenched. If sown in rows 18 inches apart, the plants may be thinned to about one foot apart, which will allow ample space for their development.

Scorzonera may also be sown and should be given similar treatment to that advised for Salsify.

Onions.—Autumn-sown Onions should now be large enough for their final thinning. If large specimens are desired, they should be left at least 1 foot apart, but for ordinary utility purposes 6 inches should be sufficient. Plants raised under glass should be gradually hardened off preparatory to planting out at an early date.

Fruits Under Glass.

Melons.—Continue to sow and plant Melons according to the requirements and convenience of the establishment, arranging the various batches to come in at a time when they are likely to be in most demand.

Hot-Beds.—In a recent calendar I advised the sowing of a batch of seeds for cultivating in frames, these to be planted early in May, so that no time should now be lost in preparing material and making up hot-beds to receive them. Such material should be turned and mixed once or twice before making up.

The Hardy Fruit Garden.

Strawberries.—After a good hoeing through, a commencement may be made to bed down the early varieties. By doing it thus early, long strawy litter may be used, and what manurial properties there may be in it will be washed into the soil, thus leaving it in a light, clean condition for protecting the fruits from dirt, &c. If left too late it is apt to cause the fruits to rot, and the use of clean straw is to be preferred.

Apricots.—These being the earliest to bloom in good warm positions, the trees may be ready for thinning the fruit—this when the weather conditions have been favourable to a heavy set of fruit. It is not wise to take off too many fruits at once, but when several are set in a clump it is certainly advisable to thin them to one or two, taking off others when in a more advanced state.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)
Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Sowing Hardy Annuals.—Now is the time to sow hardy annuals in the open. The ground should be deeply dug, but only lightly manured, especially for the dwarfier sorts and for Poppies. A good tilth is also essential to success, and the common error of sowing too thickly should be avoided. Another frequent mistake is to bury the seeds too deeply, and when they fail to germinate the seedsman is blamed. Where there are masses of English and Spanish Irises, a good plan is to sow some of the easier-grown annuals, such as Poppies, Candytufts, or Nigellas, among them for successional bloom.

Sowing Mignonette.—I believe in sowing Mignonette under glass, pricking it off into fibrous loam, and then planting it out about six inches apart; but where it is desired to sow it in the open, now is the time to do so, and I would venture to give three hints regarding its culture—manure pretty heavily, give a little lime, and coat the seeds with red lead as a protection from birds.

Weed-Killer.—Although somewhat expensive in the first instance, yet, all things considered, gravel can be kept clean more economically by weed-killer than by any other means. From now till the first week in May is the best time to apply it. It is best to do this after a moderate fall of rain. There are many kinds on the market, but we find Climax highly satisfactory.

The Rose Garden.

Suckers.—Except where Roses are on their own roots, a sharp look-out must be kept for suckers, as they soon rob the rightful owner of the ground. Cut them off just under the surface of the soil.

Rose Grubs.—Several varieties of sawfly attack Roses from time to time. Some of them can be eradicated by spraying with arsenate of lead; but there are two, *Lyda manita* and *Blennocampa pusilla*, the larvæ of which ensconce themselves in the curled-up leaves and defy the efforts of the sprayer. Hand picking is the only cure for these, and a watch should be kept for them. When

detected, the affected leaves should be promptly picked off and burnt.

The Wall Garden.

Transplanting.—Where young stock—either seedlings or rooted cuttings—are intended to fill up blanks or to take the place of present occupants, they should be planted forthwith, so as to get established before the conditions become rather dry. If possible, a stone should be removed where the plant is to be placed, and some good loam inserted in the aperture for the plant to feed on. When the planting is completed, the whole of the newly-planted stock should be thoroughly watered by means of the syringe.

Sowing Seed.—A good many of the plants suitable for wall gardens can be raised from seed sown in the future home of the plants. The seeds should be mixed with some fine soil, which should then be well moistened and pressed into the interstices which the future plants are to occupy. If dry weather sets in, give the soil an occasional spraying in the afternoons, at least till germination takes place.

Plants Under Glass.

Perpetual-Flowering Carnations.—The earliest batch of these will now be almost ready for their final shift. Seven-inch pots are generally suitable, but vigorous sorts like *Britannia* and *Mrs. Burnett* may require a size larger. These plants are by no means fastidious as to soil, but good fibrous yellow loam, with about a third part each of old Mushroom manure and Oak or Beech flaky leaf-mould, with a good dash of sand, will give good results, other points receiving due attention. Water carefully at all times, but especially after potting.

Celosias.—A batch of these from a good strain of seed is a valuable asset. They require a brisk temperature and a fairly rich soil, and should have abundance of light.

Amaranthus tricolor.—This inexpensive annual makes an excellent conservatory plant. Seed sown in a little warmth now and grown on liberally will be found very useful in the early autumn. *A. tricolor splendens* is an improvement on the type.

Fruits Under Glass.

Strawberries.—Plants that have finished fruiting need not be thrown away. If they are hardened off and then planted out in well-prepared soil, they should give excellent results next season in the open air.

Watering Vines.—This work should receive close attention, especially where there is no outside border. Liquid manure should be applied once or twice during the season.

The Kitchen Garden.

Peas.—This is the leading summer crop, and it should receive much attention. Stake promptly with Beech, Eln, Hazel, or Spruce branches if available; if not, sheep netting may be employed. Where natural stakes are bare at the bottom, small twigs should be inserted to prevent the plants from bending over, after which they never do so well. Sow successions as the previous sowing appears above the ground.

Planting Parsley.—Where a batch was raised in heat, it should now be fit for planting out. The ground should have a dressing of soot forked into it prior to planting. Plant in rows about fifteen inches apart, and from 9 inches to 1 foot apart in the rows.

Turnips.—A good sowing may now be made on the open break, but I would still recommend *Milan Early Purple* or *White*, the latter for preference.

Planting Cabbages.—Those which were raised under glass early in spring will now be ready for planting out, and it will be well to use the trowel instead of the dibber in carrying out the operation. A little extra pains will have been taken with these, and they should lift with balls which cannot be got into a dibbled hole without cramping the roots.

Cauliflowers similarly raised may be treated in the same way, but should, in addition, have a ring of soot placed round them.

Cutting Asparagus.—Inexperienced hands are apt to work mischief in this operation by cutting the roots of the plants. If the hooked Asparagus-knife is used, the danger will be obviated.

CHARLES COMFORT

Broomfield Gardens, Davidson's Mans, Midlothian.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS. *The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of THE GARDEN, 20, Finsbury Street, Covent Garden, London, W.C. The name and address of the reader are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp news or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

INJURY TO DAFFODILS (R. H. W.).—Your Daffodils are attacked by eelworms, and we doubt whether a cure is possible, for the pests, which are inside the bulbs, cannot be reached without damaging the bulbs more than they are now. The soil is probably infested with the pests, and no doubt they have entered the bulbs from that source. A heavy dressing of kaurit as soon as the bulbs are lifted would be a help towards getting the better of them, and an even greater help would be the growing of some other non-susceptible plants for two or three years on the ground the Daffodils now occupy before they are planted again.

ROMNEYA COULTERI FAILING (Miss C. E. L.).—It is difficult to suggest a reason for your *Romneya Coulteri* failing to open its flowers. Possibly it is growing in a shady position, or it may have become dry at the roots when the buds were forming. It would be a good plan to examine the soil about the roots and see what condition it is in. If it looks as if it is likely to become dry, towards June arrange to give it copious watering occasionally. It is not necessary to give new soil or manure now, as you say that the plant is quite vigorous, but if you give water when the buds are forming, a little weak manure-water may be given with advantage. Do not allow the roots to be interfered with by other plants.

THE GREENHOUSE.

INJURY TO OLEANDER (Calchester).—We can find no fungus or insect on the Oleander to account for the trouble. The stem is dead and the bark brown, but the root seems to be perfectly healthy. Is it at all likely that the plant has been exposed to frost? It has that appearance. These plants will bear a degree or two without much harm, but little more.

SCHIZANTHUS (G. B.).—We can discover no cause to account for the peculiar tufted growth on the *Schizanthus*, and think it must be inherited; that is to say, the seed may have been saved from a plant showing that peculiarity. The young plants sent appear as if they will grow out of it. You do not say whether many of your plants are as bad as the large one sent. If they are like the small ones, we do not think they will give much trouble.

GERANIUMS AND VIOLETS FOR INSPECTION (C. A.).—There is no fungus present on the *Geraniums* sent. We are inclined to think the trouble is due to the temperature and moisture conditions not being suitable for them compared with the supply of light. The colour of the Violets is, no doubt, due to their having had very dull light during the time they have been developing, and they have probably become very damp, too, judging from their appearance. Is the drainage good?

HYACINTHS FAILING (R. B.).—The Hyacinths are very badly attacked by the bulb mite, and this has caused the destruction of the roots. It is important that bulbs should be planted in fresh soil and in clean pots, and examination of the bulbs for this minute pest should be made with care when bulbs are purchased, and examination of the bulbs for this minute pest should be made with care when bulbs are purchased. Many of the bulbs lately imported have been badly attacked by this pest. Unfortunately, no method of destroying it can be relied upon to do this completely, but fumigation with carbon bisulphide is the best thing.

DECORATIVE CHRYSANTHEMUMS (Amateur).—The two varieties mentioned in your query are well-known decorative Chrysanthemums, and in consequence the question of stopping the plants with the object of producing crown buds does not apply to these plants. They should be grown to develop a free display of medium-sized flowers, and with this object in view should be stopped now and at each successive 6 inches of growth. Stop for the last time at the end of June, and from that point grow on to the terminal buds. Thin out these to suit your requirements.

AMARYLLIS LEAF FOR INSPECTION (H. B.).—The Amaryllis leaf is very badly infested with scale, which may be got rid of by sponging each leaf on both surfaces with a strong solution of soft soap and water. These pests have such a firm hold on the plant that it

is probable two or three spongings at intervals of ten days or a fortnight will be necessary in order to thoroughly eradicate them. The Abutilon, too, must be served in the same way. In the case of this, it may be possible without injuring the plant to cut off some of the worst leaves and burn them, as the plant will soon grow away again. With regard to the number of leaves to be removed, you must be guided by the condition of the plant itself.

FRUIT GARDEN.

PEACH TREES WITH STRONG SHOOTS (E. B.).—Seeing that you lifted your Peach trees last autumn and that you have cut back the strong shoots, we anticipate that the growth of young shoots from these cut-back ones will be of moderate strength only this summer, and will be in good condition for bearing full crops next year. There is no other way of preventing this excess of growth in the branches except by lifting and root-pruning. In the course of the summer side shoots will grow out of the young shoots first formed; these should be pinched back to one leaf from their base. The young shoots first formed should not be stopped, but allowed to grow their full length, as these are the shoots which will bear fruit next year.

PEACH TREE ATTACKED BY SILVER-LEAF (R. H.).—You have done quite right in removing the diseased branch, which is attacked by the disease known as silver-leaf. If you have cut the branch out beyond the point at which it shows a brown stain in the wood, you will probably have stopped the spread of the disease, but the rest of the tree may be infected, and then the best thing is to cut the tree out completely and plant another. The disease is due to the fungus *Stereum purpureum*, and no cure is known. Trees attacked rarely recover, and after death the fungus fruits appear. Infection is by spores, and the fungus gets in by a wound. All wounds should be painted with Stockholm tar as soon as made.

KITCHEN GARDEN.

PLANTING POTATOES (I. G.).—We think you have prepared one half of the plot in an excellent way, especially for early Potatoes. The second half of the plot, which has already been dug and not manured, will, we presume, be planted chiefly with later varieties. The factor is one of the best. We should dig the cow-manure into the ground. Cow-manure is cool in itself, and not good to set to come into contact with its raw state, but incorporated and mixed with light soil it is excellent. A light dressing of artificial manure could be given with great advantage, sown among the plants before the first mounding up takes place. This should be done in showery weather. Provided the manure is short and well rotted, the old-fashioned way of placing it in the furrows and planting Potatoes on top answers very well, especially with later varieties.

PREPARING ROUGH GROUND FOR POTATOES (J. C. D.).—You say the ground is now covered with coarse grass, the top turves from which would not be of much use for potting soil. However, you could stack some of the best. The best way of dealing with such land is to trench it 21 feet deep, burying the grass and turf in it, growing in 15 inches deep, and picking out every particle of the roots of the Nettles as the digging proceeds, or the ground will soon become foul with them again. In trenching, care should be taken that the best of the soil is kept nearest the surface. As soon as the trenching is finished, plant in furrows or rows in the usual way. Do not plant under turves, and do not plough, but trench. The effect will last for years. Rhubarb does well in partial shade, provided the soil is deep and well manured; also Leeks and Horse-radish. Seakale does fairly well, also the summer and autumn Cabbage tribes; but those vegetables which have to stand the winter to provide a spring supply must not be planted in a shady place as they would be too soft to stand the winter.

MISCELLANEOUS.

FUNGUS DISEASE OF HYACINTHS (J. S.).—The name printed *Pythium buranum* should, as you suggest, read *P. de baryanum*. It may be added that eelworms, bulb mites, and the fungi *Fusarium bulbigenum* and *Botrytis sclerotinia* appear very frequently to be sources of failure in bulbs.

JUDGING SCHOOL GARDEN (School Garden).—It is too early to judge a school garden, but it may encourage the scholars a little. We should wait until the seedlings are through and thinning has been done. Then give points for: Order and neatness, 10 maximum; paths and edgings, 10 maximum; straightness of lines, 10 maximum; correctness of thinning, 10 maximum; and best written labels, 10 maximum. We do not see that you can do more than this until it is possible to appraise the value of the crops, when the judging should be done on a point basis by an experienced gardener.

NAMES OF PLANTS.—M. A. B.—Daffodils: J. B. M. Camm (pale trumpet) and grandis (bicolor trumpet).—A. P. F.—Daffodils: 1, Barri Gutter; 2, Ruglobus; 3, Cernuus pulcher, 4, possibly *stella superba*, too much withered to identify with accuracy. —T. H. T.—*Saxifraga (Megasea) crassifolia*.—A. L. E.—*Lynmouth*.—1, *Erica mediterranea*; 2, *E. m. alba*.—E. K. B.—*Wimboldon*.—Berberis Darwinii. —S. G.—*Vaccinium Water*.—1, Rhododendron Rhodora; 2, R. ferrugineum; 3, *Cassia fulvida*; 4, *Lentochloa Catesbaei*.—W. F.—*Ceanothus scherzerianum*.—1, *J. Balfast*.—1, *Maxillaria picta*; 2, *Colognye cristata*; 3, *Ada aurantiaca*; 4, *Davallia canariense*; 5, *Adiantum* species.

SOCIETIES.

THE CORNWALL DAFFODIL AND SPRING FLOWER SOCIETY.

The annual show in connection with the above society was held at Truro on the 8th and 9th inst., when there was an excellent display of Daffodils and flowering shrubs. The Rhododendrons, though excellent, were not quite so good as usual, but other shrubs were very fine. The weather was fine and visitors numerous, and the Hon. John Boscawen and his staff of helpers had made excellent arrangements.

THE DAFFODIL CLASSES.

Generally speaking these were well contested, the flowers in most instances being fresh and good.

In Class I for thirty varieties of Daffodils in commerce, any section, first prize went to Mrs. Soltau Symons-Chadfieldwood, Plympton, for a beautiful lot, notwithstanding them being Whitewell, White Lady, Treasure Grove and Horace. In the second-prize group, staged by Miss Clarrice Vivian, Bosahan, St. Martin, we specially noticed Chathinch and some beautiful blooms of Scarlet Eye.

For a similar class, except that varieties not in commerce were allowed, Lady Margaret Boscawen was the only exhibitor, staging a nice group of fresh blooms. Lordet (a beautiful white Leeds), Will Scarlet, Cornish Cream and Horace called for special mention.

In Class 3, for nine distinct varieties of trumpets as defined in certain dimensions, there were three entries, first honours falling to Mrs. Soltau Symons, who had lovely flowers of Mme. de Graaft and Mrs. Morland Crossfield. Miss Clarrice Vivian was a good second, her best variety being Princess, a beautiful smooth trumpet variety almost white. Third prize went to Colonel the Hon. H. F. Franks.

For six distinct varieties of incomparablis there were four entries, Mrs. Soltau Symons again coming to the front. Miss Clarrice Vivian, Lady Margaret Boscawen and Miss Mabel C. S. Williams followed in the order named.

For six Barri—Miss Clarrice Vivian was first, Stonechat and Beacon being shown in the form. Mrs. S. Symons was second and Miss Mabel Williams third.

For six Leeds—Mrs. S. Symons secured premier honours, Miss Mabel Williams being second.

Miss Clarrice Vivian was first out of seven competitors for three Poets, staging beautiful blooms of Cornus, Cassandra and Horace.

Class 8, for fifteen distinct varieties, any section, was well contested, and Mrs. S. Symons is to be congratulated on securing the premier prize. Among her flowers we noticed good blooms of Horace and Mme. de Graaft. Miss C. C. Rogers—Birmosport, Perranwell, was second, and Mr. J. W. Jellery, Lismore, Helston, third.

For single blooms the first prize winners were as follow: Trumpet, Miss Mabel Williams, with Monarch, incomparabilis, Mrs. S. Symons, with Lady Margaret Boscawen; Barri, Mrs. S. Symons, with Cavalier; Leeds, Mrs. S. Symons, with White Lady; grandis and cyclaminous hybrids, Mrs. S. Symons, with Dorothy Kingsmill; and Poet, Miss Mabel Williams, with Cassandra. In the foregoing classes, except Classes 1 and 2, flowers grown from bulbs passed over 10s. each were excluded.

In Class 16, for fifteen varieties, any section, in commerce or not in commerce, there was a big fight between Mr. J. C. Williams, Caerhays Castle, and Mr. P. D. Williams, Llanarth, the former coming first with a grand lot shown under numbers, for which he was also awarded the Royal Horticultural Society's silver Flora medal. A fine Poet numbered 445 was about the best in the show, and a lovely incomparabilis, No. 2, was also very fine. Indeed, all were first-class. Mr. P. D. Williams in his second-prize group had some of his under names, Moonbeam (beautiful white), Pedestal, White Wax and Princess calling for special mention. Among those under numbers were some beautiful flowers, but it is useless to refer to them in detail until names are forthcoming. This exhibit was also awarded the Royal Horticultural Society's silver Flora medal. Mr. A. J. Nix, Mount Charles, Truro, was third.

In the single bloom classes in this section, all to be in commerce, the first prize winners were as follow: Trumpet, Mr. P. D. Williams, with Princess; Leeds, Miss Lavender Williams, with Lavender; Poitiers, Mr. P. D. Williams, with Snow King.

For ten distinct varieties, any section, open only to those who have never won a prize for Daffodils offered by the society, Mr. C. Birleigh, The Sportman's Arms Hotel, Menheniot, was the only exhibitor, securing the first prize with a fresh lot of blooms.

FLOWERING SHRUBS.

These were a feature of the show, the Rhododendrons and many other choice kinds being shown in abundance.

For the best group of Rhododendron blooms, any variety, not exceeding twenty varieties, there were three entries, first prize and the Royal Horticultural Society's silver-gilt medal being awarded to Mr. J. C. Williams, Caerhays Castle, for a very beautiful lot. *Argentum* was particularly good, as were a number of seedlings, a pale pink one being particularly pleasing. Second honours went to Mr. D. H. Shilson, Tremough, who had a fine fruss of the cream-coloured Nottall as well as the beautiful deep red Columbia. Mr. Robert Fox, Penjerrick was a good third, *lindleyanum* being well shown here.

The Royal Horticultural Society's silver Banksian medal was awarded to Mr. J. C. Williams for six vases of small-leaved Rhododendrons, these being intricatum, racemosum, Angustium, yunnanense, lutescens and obofolium.

The first prize for six distinct varieties went to Mr. P. D. Williams, who had a beautiful pink and also a deep red seedling. The second prize went to Mr. Charles Hext, Trebah, trebiemum (a very large-flowered pink variety) being specially good.

For six cut blooms grown under glass, Mr. R. Fox was first with some beautiful varieties, the truss of Dalhousie being particularly fine.

For the finest cut blooms of Rhododendrons grown under glass, the premier award went to Mr. J. C. Danbuz, Killow, Truro, for a wonderful truss of Nuttallii, the flowers being large and very clean.

The class for three large jars of outdoor Rhododendrons was very pretty, first prize going to Mr. Robert Fox, Penjerick.

For a group of outdoor unforced flowering shrubs or climbers, the first prize and the Royal Horticultural Society's silver-gilt Banksian medal went to the Rev. A. T. Boscawen, Ludgvan Rectory, Long Rock, who put up a really wonderful lot. We need only mention such as *Acacia verticillata*, *Viburnum Carlesii*, *Bonia heterophylla*, *Pittosporum eugenoides* and *Prostranthera violacea* to give readers some idea of his favourable clime. The second prize and the Royal Horticultural Society's silver Banksian medal went to Mr. T. B. Bolitho, Trevidden, who showed, among other interesting plants, *Embothrium coccineum*, *Grevillea sulphurea*, *Viburnum rhytidophyllum*, *Dendromecon rigidum* and *Abutilon vitifolium*. In the third-prize group, shown by Mr. R. Fox, Penjerick, and which also carried the silver Banksian medal of the Royal Horticultural Society, we noted such varieties as *Anopteris glandulosa*, *Drimys Winteri* and *Pittosporum eugenoides*. Fourth prize went to Sir Arthur P. Vivian, Bosahan, Clanthus pumicis and the white variety, *Clematis indivisa* and *Cytisus racemosus* being well shown.

For six varieties of outdoor unforced hardy shrubs, the first prize and the Royal Horticultural Society's silver Banksian medal were well won by Mr. P. D. Williams, who had *Veronica macrocarpa* and *Erica australis rigida* in splendid condition. Sir Arthur P. Vivian was second, having grand varieties of *Drimys Winteri* and *Clematis indivisa*. The third and fourth prizes went, respectively, to Mr. A. P. Bearne and Mr. C. Hext.

In a similar class, but confined to those who have never been awarded a prize offered by the society in these classes, the first honours went to Mr. E. Beard, Boscawen Park, Truro.

Violets were well and freely shown, the blooms being large and of good colour. A harmless joke was attempted in this section, scented flowers of the double *Periwinkle*, *Vinea minor*, being staged as a new Violet! Needless to say, the judges discovered the joke and dealt with it officially.

For Roses Lady Margaret Boscawen and Mr. A. Bleaningsop were the principal winners, the last named showing a fine vase of *Catherine Mermet*.

The classes for Polyanthuses and Primroses, three varieties of each, were splendidly contested, the plants being shown in round wicker baskets. Mr. A. P. Worth, Lemon Street, Truro, was first for Polyanthuses, and Lady Margaret Boscawen for Primroses.

For a collection of hardy unforced spring flowers, twelve varieties, not to include hard-wooded shrubs, Mr. P. D. Williams was first, staging, among other varieties, *Oursia macrophylla*, *Epimedium sulphureum* and *Callia polypetala*. The second prize went to Mr. T. B. Bolitho, and third to Lady Margaret Boscawen.

NON-COMPETITIVE GROUPS.

Captain T. A. Dorrien-Smith, Isle of Scilly, staged a wonderful collection of plants of botanical interest. We doubt whether so good a collection has ever before been shown. Among others, *Bescheronia tucoidea* with a flower-spike 5 feet long, *Brachyglottis repanda*, *Correa myrsina*, *Grevillea sulphurea*, *Correa cardinals*, *Acacia longifolia*, *Sophora tetraptera grandiflora*, *Echium callithyrsu*, *Acacia verticillata*, *Fuchsia cordifolia*, *Psoralea affinis*, *Sedum arboreum*, *Correa alba*, *Agonotis marginata*, *Blechnum anisatum*, *Pittosporum Tohira*, *P. tenuifolium*, *P. L. Mayii*, *P. Raphii*, *P. Colensoi*, *P. undulatum*, *P. bicolor*, *P. cornifolium* and *P. eugenoides* were some of the most interesting. A group such as this staged at a London show would create much interest. Royal Horticultural Society's gold medal.

Messrs. K. Veitch and Sons of Exeter put up a miscellaneous group, mainly composed of choice hardy plants, *Cianthus pumicis*, *Olearia insignis*, *Daphne Cineorum*, *Osmanthus Delavayi*, *Ribes cereum*, *Psoralea arborea*, *Gerbera Jamesonii* hybrids, *Primula helvetica nivalis* and *Anemone Pulsatilla* were some of the most interesting that we noticed. Royal Horticultural Society's silver Flora medal.

Mr. G. Reulle, Keston, Kent, staged a comprehensive group of alpine and shrubs, Rhododendrons being conspicuous among the latter. Of the rock plants, *Primula nivalis* hybrids, *Saxifraga Bertolonii*, *S. Boydii*, *Primula Julia*, *P. glutinosa* and *Saxifraga Stribneyi* called for special mention. Among many interesting shrubs we noticed cut flowering sprays of *Illicium floridanum*. Royal Horticultural Society's silver Flora medal.

Mr. C. Bourne, Bletchley, had a small but very beautiful and splendidly-arranged exhibit of his famed Narcissi. These included a number of good new sorts, a few that specially appealed to us being *Red Lady*, *Queen of Hearts*, *White Countess*, *Countess Grey*, *Florence Pearson* and *Mrs. Robert Sydenham*. Silver-gilt Flora medal of the Royal Horticultural Society.

Messrs. Barr and Sons, King Street, Covent Garden, staged a fine lot of Dalhousies, the arrangement being superb and in excellent taste. Among other varieties calling for special mention were *Clematis*, *Lord Roberts*, *Mrs. G. H. Barr*, *Venus*, *Charm*, *Cour d'Or*, *Royal Star* and *Lord Kitchener*.

Mr. J. C. Martin, Truro, staged a nice group of Narcissi, *Brimette* being one that called for special mention. Several rather attractive red-eyed seedlings were also among this group, to which the Royal Horticultural Society's silver Banksian medal was awarded.

Messrs. Treseder and Co. of Truro put up a collection of hardy Tree Ferns, *Acaenas*, *Boronia*, *Hydrangeas*, *Ericas*, and forced *Roses* and other greenhouse plants, the whole being well grown and clean. This firm also had some nice rock garden plants, *Gentiana acanthis* being particularly pleasing.

From the Devon Rosery and Fruit Farm, Limited, came a collection of *Roses* in pots and some well-preserved *Apples*, the latter including such varieties as *Annie Elizabeth*, *Bramley's Seedling* and *Newton Wonder*.

Mr. Jephson, Hensford, Cornwall, staged a miscellaneous lot of alpine plants. *Primula helvetica nivalis*, *Embothria ovata*, *Silene Hookeri*, *Onosma turica*, *Primula Forrestii*, and several unnamed seedling *Saxifrages* lent interest to this group.

A beautiful plant of *Grevillea hookeriana* was shown by the Rev. A. T. Boscawen, Ludgvan Rectory. This is a native of West Australia and a very rare plant in this country. The specimen shown was a splendid example of the gardener's skill, the blood red inflorescences reminding one of giant tooth-brushes. This received a first-class certificate from the Royal Horticultural Society.

Awards of merit were granted by the Truro Society to the following: Mr. P. D. Williams for *Camellia Lady Buller* and *Oursia macrophylla*; the Rev. A. T. Boscawen for *Pernettya ciliaris* and *Pentstemonis rugosum*; Messrs. Barr and Sons for *Narcissus Venus*; Mr. C. Bourne for *Narcissus Golden King*; Mr. J. C. Martin for *Narcissus Silver Penny*; Mr. Reulle for *Rhododendron Elsa*; Messrs. R. Veitch and Sons for *Osmanthus Delavayi*; and Mr. Jephson for *Primula Forrestii*.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

The annual spring show of this society was held in the Waverley Market, Edinburgh, on April 9 and 10, and proved a most interesting and attractive one. The competitive section was of high excellence. In few of the classes was there any reduction of quality from that of former years, while in many there was a marked advance. The trade exhibits were remarkably good for the spring show, and they gave a brightness and quite an effective appearance to the large area of the market. The show was opened on the afternoon of the 9th by the Marchioness of Linlithgow in a brief but appropriate and graceful speech. It is impossible to do justice to the trade exhibits in the space available, and it is only possible to refer briefly to the leading features in a few of the stands.

Messrs. Dobbie and Co., Edinburgh, made a magnificent display, occupying a large space on one side of the market, their exhibit being marked by the high quality, exquisite condition and tasteful arrangement always present in their show exhibits. The group of spring bulbous plants included many of the choicest Narcissi, Tulips, Hyacinths and other subjects of this nature, with lovely *Violas*, these making quite a show in themselves. A grand group of *Roses* in pots was also exhibited, these comprising such flowers as *Jessie*, *Juliet*, *Rayon d'Or*, *Melody*, *Mrs. Taft* and many more. Adjoining these was a fine group of *Cinerarias* in the various classes, followed by a bank of magnificent *Calceolarias*. A large and representative collection of *Potatoes* was also exhibited by the firm. Gold medal.

One of the finest things in the show was the extensive exhibit on the floor of Messrs. R. B. Laird, Dickson and Sons, Edinburgh, this being a truly grand group of forced and other shrubs, together with other flowering and decorative subjects. Admirably arranged and composed of a number of the best Rhododendrons, Lilies, Azaleas and *Roses*, this group attracted much attention and well deserved the gold medal it received. It was highly creditable as the first public exhibit of the incorporated businesses of the two old firms of Messrs. R. B. Laird and Sons and Messrs. James Dickson and Sons.

Messrs. Dickson and Co., Waterloo Place, Edinburgh, set up another very fine exhibit on the floor. The finest feature here was the grand lot of *Hippeastrums* (*Amaryllides*), these being of exceptional beauty and quality. The group, which was an extensive and highly tastefully arranged one, included *Azaleas*, *Rhododendrons*, fine standard *Zonal Pelargoniums*, *Lilies*, *Tulips* and *Narcissi*. Gold medal.

From Mr. David King, Osborne Nurseries, Edinburgh, came a glorious group of plants and flowers, which practically occupied one end of the market, and which was arranged in a manner which gave much pleasure. A low bank of plants, arranged in a winding outline, with turf in front, it contained a number of good things, such as *Roses*, *Lilies*, *Cytisuses*, *Rhododendrons*, *Ferns*, *Palms*, and other flowering and foliage plants. Mr. King, who is the president of the Scottish Horticultural Association, received much praise for this group. Gold medal.

Another striking exhibit, which also received a gold medal, was that of Messrs. J. and A. Glass, Edinburgh, who sent a magnificent lot of *Carnations*, these including the best of the present-day varieties, splendidly grown and shown.

A silver-gilt medal was given to Messrs. Cunningham, Fraser and Co., Edinburgh, for their alpine plants, arranged on rockwork and including a number of good alpinists, both old and new. The *Primulas*, now so popular, were represented by the new *P. pinnatifida*, *Forrestii*, *giraldiana* (syn. *muscaroides*), *littoniana*, *hirsuta* variety *nivea*, *decora*, *d. alba*, a number of the *viscosa* hybrids, *pulverulenta* and others, while the other plants in this choice display included *Morisia hypogaea*, *Androsaces*, such as *pyrenaica* and others; *Haberleas*, *virginalis*

being among the number; *Saxifrages* *Faldonside*, *Boydii*, *Cherrytrees*, *Arkwrightii* and many others, with *Anemones*, *Heaths*, &c. The little *Rhododendron Grievei*, raised originally by Mr. James Grieve, was delightful with its dwarf habit and soft pinkish or rose and white flowers.

A similar award went to Messrs. Cutbush and Son, London, for a most creditable exhibit of alpinists, *Carnations*, &c. The *Carnations* made a brilliant and effective group, prominent among them being *Mrs. E. C. Raphael* and others, while the alpinists comprised, among many others, the pretty *Saxifraga Miss Willmottii*, the double blue *Hepatica*, *Tulipa platystemon*, *Iris orchroides* and a number of other good things.

The Orchids of Messrs. Sander and Sons of St. Albans were honoured with a silver-gilt medal, the small but choice group including a number of real merit and rarity which space prevents detailing.

The large group of Messrs. Storrle and Storrle, Glencarse, N.B., received a similar award. Not-worthily here was the mass of *Primula obconica* of the highest quality, showing in a marked degree the improvements effected within recent years. In colour, size of truss and of individual pips these plants were admirable. *Cinerarias* of equal quality constituted the other leading feature of Messrs. Storrle and Storrle's exhibit.

A silver-gilt medal was also given to Messrs. Young and Co., Hatherley, Cheltenham, for one of their magnificent displays of *Carnations* of the most modern type; and to Messrs. Hogg and Robertson, Dublin, for a grand array of *Narcissi*, *Tulips* and *Anemones*, these all being very fine and well displayed.

From Messrs. John Forbes, Hawick, Limited, came a varied and interesting group of *Streptocarpus*, *Caladiums*, *Azaleas*, *Primroses*, *Polyanthuses*, *Auriculas*, *Primula* species, *Viola gracilis* and florists' *Violas*, with *Cytisuses* and a number of other good things. Silver medal.

Mr. Clarence Elliott, Steveage, staged a good variety of alpinists, shown on well-arranged rockwork. In good masses, these looked well in the natural arrangement of the rocks. The plants included *Lithospermums*, *Gentiana acanthis*, *Ethionema ibericum*, *Androsace carnea*, several of the best red Mossy *Saxifrages* and others of the genus, *Oxalis cuneaphylla*, *Primulas*, *Senpervivums* and *Sedums*. A silver medal was awarded.

Messrs. J. Piper and Son, London—new exhibitors here—had a capital group of alpinists and shrubs suitable for rockwork. A leading feature was the collection of *Primulas*, including a most varied set of *viscosa* hybrids, mostly under numbers only. *Mrs. Robinson*, yellow, was good, though approaching some of the old *P. Auricula* forms. *Sarracenia*, *Saxifrages*, *Gentianas* and *Antrietias* composed a group which attracted much notice. Silver medal.

A silver medal went to the Liverpool Orchid Nursery (John Cowan), Limited, for a handsome group of good *Orchids*; Mr. T. E. Dawes, King's Lynn, for *Rhubarb*; and Messrs. Thyme and Son, Dundee, for a capital stand of alpinists and other hardy flowers. A bronze medal was awarded to Messrs. Reamsbottom and Co., Geashill, King's County, Ireland, for *Anemones*.

The decorated dinner-tables brought out a capital competition, and the judges must have had some difficulty in arriving at a decision. Mr. J. Wilson came first, with Mr. J. Hood second and Mr. D. Kidd third.

Fruit was limited to two classes, and Mr. G. Anderson was first for a dish of Strawberries, Mr. T. M'Phail winning a similar position for bottles of fruit.

Vegetables formed a most attractive section, Mr. R. Stuart winning for the collection of vegetables and also for the collection of salads. Other winners were Mr. W. F. Staward, Mr. D. Fraser, Mr. J. Cossar, Mr. W. G. Pirie, Mr. J. K. Brown, Mr. J. Paterson and Mr. G. M. Service.

In the under-gardeners' competition for a plan of laying out thirty-eight acres, the following were announced as the prize-winners: First, Mr. H. G. Oliver, Edinburgh Royal Botanic Gardens; second, Mr. J. W. Forsyth, Markyate Gell, Herts; third, Mr. Archibald Macey, Godington Gardens, Ashford, Kent.

Non-competitive exhibits by private exhibitors were *Brachyglottis repanda*, a pleasing New Zealand shrub, from the Marquis of Linlithgow; and splendid pans of *Saxifrages* *Boydii*, *Faldonside*, *Cherrytrees* and *pyrenaica* splendens, from Mr. W. B. Boyd, Faldonside, Midlothian.

The arrangements of the council and of Mr. Mackenzie, the secretary and treasurer, were excellent.

DUMFRIES AND GALLOWAY GARDENERS' ASSOCIATION.

MR. S. ARNOTT presided over the fortnightly meeting of this association in St. George's Hall, Dumfries, on April 5. There was a large attendance to hear the paper by Mr. James Henderson, The Gardens, Elibank, Dumfries, on "The Chrysanthemum." The paper was in every way an excellent one, dealing with the various classes of the flower from a purely practical standpoint. Mr. Henderson, as he stated at the outset, refraining from discussing the question of the history of the flower. He pointed out its beauty and utility, and then passed on to speak under separate heads of the three leading divisions into which he grouped his flowers. These were the early-flowering, the decorative midseason varieties, and the late-flowering or exhibition flowers. In each of these sections Mr. Henderson gave full directions regarding their propagation and cultural after-treatment. Abounding with humour, the paper was closely listened to and much enjoyed. A spirited discussion took place, the points principally raised being: Time of propagating autumn varieties, the effect of the use of nitrates on the duration of the blooms, single pots or boxes for cuttings, the cure of rust and other subjects of importance. Mr. Henderson replied on the discussion, and received a warm vote of thanks.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

The Best Bedding Pelargonium.—At the trial of bedding Pelargoniums held by the Royal Horticultural Society at Wisley last year, it was proved that there was no advance on some of the older and well-known varieties. Paul Crampel was considered to be much the finest scarlet-flowered bedding variety in the whole trial, which included ninety-eight stocks.

Large Prize for a New Rose.—Raisers of new Roses will learn with interest that the management of the Panama-Pacific International Exhibition, to be held in San Francisco in 1915, are offering a cup, value 1,000-0-0, in addition to any award that the horticultural jury may vote, for the best new Rose that is shown. Amateurs and professionals will be entitled to compete, but the Rose must be unnamed and must not have been previously exhibited.

White Hepaticas in the Rock Garden.—A charming effect has been produced in the rock garden of the Royal Botanic Gardens, Edinburgh, by the tasteful manner in which a number of plants of the white Hepatica, *Anemone Hepatica alba*, have been planted. On a somewhat steep portion of shelving rockwork, rising to 6 feet or more high, the Hepaticas were planted along the little terraces between the shelving rockwork. The effect in April has been remarkably pleasing, the pure white flowers of the Hepaticas showing in an exquisite way against the dark stones. The position appears to be a partially shaded one.

A Good Plant for Shade.—*Hypericum calycinum*, commonly known as Rose of Sharon or St. John's Wort, will be found useful for planting in shady places, such as under trees, providing these are not exceptionally dense, where it is sometimes difficult to get grass to become established. The plants are easily increased by division, and pieces with roots, planted now, will soon furnish ground which would otherwise remain bare. It is advisable to plant thickly to get the ground covered in a short time, and apart from cutting off the old growths in the spring, when the new ones appear, the plants will need little attention.

A Gorgeous Tulip.—One of the most interesting flowers in our garden just now is *Tulipa fosteriana*, a beautiful species from Bokhara that deserves to be grown wherever Tulips are appreciated. The immense goblet-shaped flowers are rich scarlet, glowing as a furnace, with a rich yellow centre, in which are delicately poised slate blue anthers. We have given it a warm corner in deep, loamy soil, and there it seems quite happy. The largest flower measures 6 inches from the base to the tips of the petals, the largest of which is 2½ inches wide. The foliage is large and pale, almost glaucous, green in colour, and the flower-stems attain a height of about eighteen inches.

This species received a first-class certificate from the Royal Horticultural Society in 1906, but as yet seems to be little known. Mr. Jacob must assist us in spreading its virtues.

Lime-Sulphur versus Bordeaux Mixture for Spraying Potatoes.—Experiments conducted at the New York Agricultural Experimental Station last year proved that a solution of lime-sulphur cannot be recommended as a spray for the Potato disease. On the other hand, six applications of Bordeaux mixture increased the yield of marketable tubers at the rate of 111.5 bushels per acre. The lime-sulphur wash dwarfed the plants, though it did not appear to burn the foliage. On the other hand, the Bordeaux mixture prolonged the life of the plants about two weeks.

A Good Annual for Cutting.—When sowing hardy annuals, the Sweet Sultan should not be forgotten, as for border embellishment it cannot be surpassed. The flowers remain fresh in water for a long period, and are therefore valuable as cut flowers, being very effective either in vases alone or mixed with Fern, light Grasses, or with Gypsophila. The seeds should be sown where the plants are to flower, and the best results are obtained from plants that are well thinned. There are several beautiful varieties. The Bride (white), The Bridegroom (heliotrope), The Bridesmaid (yellow) and splendens (rich wine red) are some of the most distinct, although a mass of mixed shades is very attractive.

Hardy Annual Calceolarias.—Among the many hardy annuals, few are more deserving of a place in our gardens than the annual Calceolarias. Seeds of these sown now in beds or borders containing Aquilegias, Sweet Williams, or similar early-flowering plants will make such beds look bright at the latter part of the summer when the permanent occupants are over. They are easily grown. Seeds may be scattered among the early-flowering plants and raked in the soil, which should be fairly rich. A good watering occasionally during the dry weather is all that will be found necessary. *Calceolaria chelidoniifolia*, *C. pinnata* and *C. mexicana* are the most commonly known, each being useful for this purpose.

Potatoes as a Cure for Headache.—Those who have hitherto regarded the humble Potato solely as a wholesome and useful vegetable will be interested to learn that it possesses other virtues. According to a short article in the *Lancet* for last week, the small doses of poisonous solanine contained in a healthy Potato "are stated by some authorities to be an excellent sedative, and more efficacious in long-standing neuralgia than either antipyrine or antifebrin. We have little doubt that oftentimes a judicious diet of Potatoes would be of greater benefit to a good many self-physicking people than a dose of some antipyretic substance which they regard as adapted to relieve all headaches, whatever their origin."

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Rose Blush Rambler.—This single-flowered climbing Rose is one of the most vigorous-growing varieties suitable for outdoor cultivation, and for clothing arches, pergolas or verandahs has few equals. It blooms comparatively early, and produces its large trusses of blush flowers in great profusion. The accompanying illustration, showing this Rose growing on a house at Bexhill, was kindly sent to us by Mrs. Mainwaring, Bembridge, Isle of Wight, and well depicts the free-flowering characters of this charming Rose.

Anemone robinsoniana cornubiense.—Here we have a very pretty Wood Anemone, resembling the lovely blue *A. robinsoniana*, save that the exterior of the buds and flowers is red, this colouring giving a special brightness to the buds and to the flowers when they are closed. This is a charming little Wood Anemone, easily cultivated in semi-shade, shade, or even sun, but preferring a light,

ROSE BLUSH RAMBLER IN A READER'S GARDEN AT BEXHILL.

rather open soil, though this should not be too loose. It is as hardy as the common wild Wood Anemone, and tubers should be procured in early autumn and straightway planted about two inches deep.—S. ARNOTT, *Dunfries*.

Caterpillars on Fruit Bushes.—Paris green is about the only effective remedy for these pests. It can be mixed with water and applied, but the best method of preparation is to make up some lime-water in the usual way, and into every five or six gallons stir 1 oz. of Paris green. Churn them well together, then spray as finely as possible over the bushes and trees. A week later syringe with lukewarm water, in order to remove the substance from all fruits. This method is one of the most effective, but should not be adopted within a fortnight of the date when the fruit is to be gathered, as the Paris green is poisonous. If the spraying is performed after picking the fruits, allow the substance to remain on the foliage. It will do no harm and keep off pests.—HUGH H. AITKEN

Berberis verniculosa.—This new Barberry promises to be a good subject for the rock garden if it at all fulfils the expectations one forms from seeing plants in pots. This was in the Royal Botanic Gardens, Edinburgh, where little specimens not more than 3 inches or 4 inches or so in height were bearing a number of their bright yellow flowers along with their pleasing, small leaves. I am not certain whence this charming little *Berberis* comes, but it is probably a Chinese species. Should it turn out to be as hardy as it looks and to retain its dwarf habit, *B. verniculosa* will achieve some favour from cultivators of rock plants.—S. A.

Wallflowers for the Cold Greenhouse.—Readers who have unheated greenhouses in which they would fain see flowers throughout the winter may like to try Wallflowers, which with me have been continuously in bloom from October to April. Formerly I tried seedling plants, such as those used for spring bedding, but these did not flower before the end of February. Last May, when the spring bedding Wallflowers were cleared away, I saved some of the best-shaped plants, potted each into a 5-inch pot, and sunk them where space

offered in a mixed border. There they were left till October, when they were removed to the cold greenhouse, and were very shortly in bloom, as they have continued ever since. *Primrose Dame* was the variety used.—M. KENNY, *Cambridge*.

Failure of *Anemone fulgens*.—As Mr. Arnott asks, on page 181, issue April 12, for opinions about *Anemone fulgens*, I may say that here in Surrey it flourishes well, but not in the natural soil, which is poor and sandy. We find it will only do well in the moister parts of our garden. Each year it flowers in abundance during about two to three months on the lower parts of a small rock garden in which the soil is entirely made up of good, light loam with some leaf-mould mixed with it. In this part of the garden the natural subsoil is rather moist sand. The plants are in full sun, but they also do equally well in a small bed with the same subsoil where they only get the midday sun. The flowers sometimes begin before January is over, but this year they did not begin till the end of February.—TIMMUS FUGIT

How to Grow *Saxifraga burseriana*.—I am interested in "Alpinist's" very considerate challenge on the above subject, page 191, April 19 issue. I am very grateful to him for not dealing more harshly with one whom, I fear, he has proved a false prophet. I will frankly confess that *S. burseriana* puzzles me. Mr. Elliott, whom I took with me for our first sight of the plant in one of its *loci classici*, will bear me out when I say that it there luxuriates on lime silt in a very deep and sunless gorge, and there alone. Similarly I have since seen it in the Schlern Klamm, the same great Tridentine form, but less abundant and less luxuriant. (But there was born *S. b. Gloria* and by me collected.) And here also it appears, though less rigidly, to shun the more open and sunny places. Finally, on the high crest of the Hoch Ober, in the Karawanken, *S. b. minor* may be found in enormous masses, always, for choice, on the under side of the shelving tussocks, though exposed to all the wind and rain along the mountain's neck. It was under the influence of these experiences that I declared the plant (in "The Rock Garden") to "detest sunshine and open positions." I do not think that the allusion or general prescription for the whole race of *Kabschia* in "My Rock Garden" is really contradictory to this, as it has to cover so much wider a field to generalise about the section, rather than prescribe specifically for one member of it. At the same time, I incline to think that the more general statement may perhaps be nearer to horticultural truth (as conditions so vary) than the stronger pronouncement of "The Rock Garden," though this as a fundamental fact of the plant's natural requirements should always be kept in mind. At the same time, "Alpinist" must remember that "dry and sunny," "cool and shady," mean very different things in almost every garden of almost every English county, and a very, very different thing, again, from the sun and shade of the Salurn Gorge or the Schlern Klamm. I myself mean by "detests sun and open positions" merely that—having so often seen *burseriana* in Southern gardens fried and frizzled out of life by being planted in the "dry, sunny positions" in which Mr. Robinson hopes it will soon form good-sized tufts—now I should always advise cultivators in hot counties to give it a northerly or westerly exposure. Is it possible that "Alpinist" thought I meant that it should have positive shade of bush or tree? In this case I apologise for my obscurity. No wonder I have been found a false prophet. I am certain that *burseriana*, if it is to grow well in full sun in Southern Counties, depends on very perfect conditions of drainage and underground moisture. Generally speaking, to elaborate and clarify my prescriptions, I advise growing it in some quite open and unshaded position, but in one which does not get the full fury of midday summer heat, unless it be well watered from below and in a soil that suits the demands of such a baking situation—very loose, that is, with chips and lime rubble freely mixed with a light, rich compost. My own experience with the plant is valueless, for here (where the sun is pale) it grows without trouble in almost any aspect. But even here I should not give it my hottest situation. But in any case I am sure we must never forget that the very best forms of the plant—*Gloria* and *magna*—are only to be found in deep and darkish gorges, where they are protected from the rages of an Italian sun and summer, not by tree or bush, but by the vast encompassing walls of limestone on either hand.—REGINALD FARRER.

A Hint when Syringing.—When using the syringe for spraying bushes with an oily or soapy emulsion, great difficulty is often experienced in holding it sufficiently tight to develop the required force necessary for successful work. If this is so, a band of metal should be soldered round the barrel at the most convenient point; a piece of corrugated brass or lacquered metal raised a quarter of an inch in the centre gives a secure hold. I have also seen a syringe having a piece of thick copper wire tightly wound round the barrel and soldered in position for the same purpose. A plumber will do the work for a few pence.—H. A.

A Rose Note.—Some weeks ago one or two Northern correspondents complained of the winter's havoc among their Rose plants. Happily, no such ill-effects have to be chronicled from this district. But had severe frosts visited us, I believe we should have fared equally badly, for as one has gone through the pruning operations, the soft and pithy state of so much of last year's wood is all too evident, thus making it necessary to cut some growths practically to the ground which otherwise ought to have been left with three or four good eyes. I presume this want of firmness in the wood is due to last year's lack of sunshine.—C. TURNER, 3, Kenwood Road, Htshgate, N.

How to Destroy Ants.—Ants are often troublesome pests during the summer. A weak solution of carbolic acid, one to three parts of the ordinary commercial substance to 100 parts of water, is a good liquid to spray in places which they frequent; but a good insecticide is equally effective. Vaporite, a substance often advertised in your columns, is even better than the carbolic solution. I have also heard of boiling water being used successfully, as the insects do not love a moist halation, even should they not be killed by the heat. If the nest can be found, it ought to be flooded with water, or liberally treated with some poisonous substance or a strong insecticide like Vaporite.—HUGH H. AITKEN.

Double-Flowered Pink and Rose Almonds.—Among hardy flowering trees that adorn our gardens in early spring, those having flowers of a deep pink or rose colour are none too numerous, and amid the general run of white, yellow and blue flowered subjects their ruddy colours stand out conspicuously. Exceedingly picturesque at the present time is *Prunus Amygdalus Clara Meyer*, whose leafless branches are thickly set with deep pink flowers like miniature semi-double Roses. The flowers are exceedingly lasting, are not readily marred by adverse weather, and the trees are floriferous even in a young state. In *Prunus persica rosea plena* we have a double rose-coloured form of the Peach, while in the variety *magnifica* the flowers are of a much deeper shade. All these forms of *Prunus* are exceedingly ornamental, either as bushes planted in grass—at least a yard around the stems must be kept clear of grass—or as standards, singly as specimens, or grouped among other shrubs.—THOMAS SMITH, *Coombe Court Gardens*.

MY EXPERIENCE WITH THE NARCISSUS FLY.

(*MERODON EQUESTRIS*.)

IN writing of the Narcissus fly, I do not make any pretensions to profound knowledge, but I can see things are not exactly as we have been taught, and for this reason I have taken upon myself to put forward the points at variance with accepted orthodoxy. My first knowledge I gathered from the Rev. S. E. Bourne's "Book on the Daffodil," but my experience has led me to see that things are not exactly as described there, so I am now anxious to get a more perfect knowledge and to get others interested, so that by combined investigation we may find out the real life-duration of the larva and other matters connected therewith, which will clear away the mists at present surrounding the mystery. It is necessary that we should have proof of the position of the egg as it is deposited by the fly. This can be done by watching the female while occupied in this work. Then we need strong proof of the direction the newly-hatched larva takes, as it is a keenly-disputed point whether it works its way down the foliage inside the bulb or outside, entering from below. The approximate date of change from larva to pupa ought also to be known.

In 1909 I had a bed of Emperor Narcissi nearly destroyed by the fly. I took about thirty of the

THE NARCISSUS FLY (*MERODON EQUESTRIS*) WITH LARVA AND PUPA.

bulbs having larvae therein and planted them in soil in a box, over which I placed a sheet of glass, so that none could escape. In March, 1910, the first fly metamorphosed; others followed in a few days, and I fed them with honey, but they did not live more than eight or ten days. May was the most prolific month. One of these larval grubs was of quite nomadic tendency; it left its home and wandered in the soil until it found a hole in the side of the wooden box from which a small knot had fallen, and in this it was jammed. No doubt its food supply had failed and it was in search of fresh quarters. Let it be noted that I found this larval grub thus jammed in April, at a time when it ought—according to accepted theories—to have been in its chrysalis state. This is one of the several points I did not grasp as I ought to have done until too late, but I think it will go a long way towards proving my theory of a two seasons' larval state. I did not then give it proper consideration. I was, after this, better acquainted with the fly, and began to watch for it in the garden. I found by experience that from 11 a.m. to 3 p.m. was the best time, and got into the habit of leaving all other work at those times so that I might give my undivided attention to their destruction. My method of capture was as follows: After accustoming my eyes to recognise the fly on the wing, I watched until I saw it drop on the soil near the

beds; then, holding my net about two feet from the ground, I cautiously drew within striking distance, then dropped the net over it and flattened it out with my fingers as quickly as possible. I found that when the fly rises, being disturbed, it will, as a rule, settle again further along the bed; but if missed when struck at, it vanishes like magic to some distant retreat. I have, however, seen others take a turn round of, say, 20 yards, then as suddenly return and drop within striking distance and be caught. This is more especially so when the fly has been hatched on that particular bed—at least, I have thought so.

I saw no flies on the wing after June 25. In 1911 the season opened cold and wet, and I saw no flies until May 25. After this they came out daily, until I caught as many as twenty-seven in one day; then, dwindling in number, I caught the last on June 21. I kept a diary, and totalled a bag of 127 males and fifty-seven females. I experienced a great joy, believing I had caught the last. I have proved my imagings sadly deficient. According to Mr. H. C. Long, *Gardeners' Chronicle*, October 12, 1912, the laying capacity of each female fly for one season is stated to be 100. I do not accept that. I have several times dissected the female, and with a cambric needle counted sixty, more or less, but always within half-a-dozen of that number. If, therefore, the number of bulbs destroyed in a season was based on the 100 product it would be very misleading. This year I caught fifty-seven females, and this number multiplied by sixty, which I consider correct, gives $57 \times 60 = 3,420$, representing the total number of bulbs that might be destroyed.

In 1912 the fly rose early, my first catch being on April 20. The Daffodil period was very early, too, and much difficulty was experienced by growers in keeping their flowers for the shows. The season was warm and the flies were very active. I was very active, too, and did not sit down to watch them grow. I took my "gun" (I always call it so) and went afield after the game. Last year I found it very late at work, and my last kill was on July 8. When I drew my balance I found I had a bag of thirty-eight males and sixty-six females. It is impossible to calculate the extent of the losses, because there is so much we cannot compute; for instance, small side bulbs suffer terribly when the large bulbs are affected. I consider this fly-catching method far outstrips any other scheme for the destruction of the flies. Here they are all killed before the breeding begins. In other methods, you must wait until a new generation of flies is at work in the bulbs. I often think of the old adage, "A bird in the hand is worth two in the bush."

A rather remarkable thing came under my notice last year. On March 26 I took up a bulb of Mme. de Graaff, owing to the ill-conditioned state of its foliage. Searching for a cause, I found a full-grown larval grub, and it set me wondering as to why that grub was still in a larval state—it really ought to be a chrysalis. I felt there was something wrong. I wanted to know *why*, so I prepared another bulb by cutting it in two and scooping out a portion to fit the grub in. I then put nails through it and stowed it away to keep it under observation. On June 25 I found another bulb having a full-grown larval grub, and I treated it in the same way. The nomad or tramp larva, previously referred to, now came to my memory, strongly confirming my theory of two seasons' larval existence. Keeping the two bulbs under observation until October 20, they were examined, found alive, and planted in soil in a flower-pot

There can be no question about them, but I shall keep an eye on them, all the same. Respecting this two seasons' larval life, I found a very strong confirmation of this in the *Gardeners' Chronicle*, October 19, 1912, from the pen of Mr. A. J. Bliss, F.R.H.S. He had a harvest of about ten thousand bulbs, and owing to the prevalence of the fly he made a most careful search for the larvæ and found from thirty to forty, each being about a quarter of an inch long. He also found three other larvæ three-quarters of an inch long. Not having arrived at my two seasons theory, he attributed those of the smaller size to some mysterious retardation while still in the egg state. He thinks the eggs remained dormant for some time after oviposition. Of course, this second season in the life of the larvæ must not now be lost sight of, but be followed up for fuller corroboration. All the same, it appears as plain as a pikestaff that two seasons must have been occupied in the life of the two I have under observation and the three named by Mr. Bliss.

With reference to fly identification, we have much instruction towards this that is helpful, but it needs repeating for amateur guidance. I would therefore put the method thus: The fly has many varied hues, is covered with short hairs, and very much resembles the worker female of the field bee. In flight it is more like the domestic drone bee, with a manoeuvring similar to the blue-bottle fly. The colour is black, or black banded with grey, yellow, old gold, pinky russet, or sometimes all grey or yellow.

Methods for its Destruction.—1. First and best is a proper net to catch the fly. No other method is so effectual. 2. A constant watchful eye early in the morning when the fly is leaving its cocoon, or it may be found with wings not expanded, or even in the cocoon on the bed. It may also be found dormant on hedges, Box edging, Potato, Bean and Pea haulm and similar places. 3. A rigid inspection of all bulbs every time they change hands (raiser, sorter, packer, buyer and planter), and if this be done the beds will receive the benefit and the fly will cease to terrorise. 4. A close examination of bulbs where distorted damage exists or where they do not grow properly, also of the beds round such, to find the chrysalis, in March, April, May and June. 5. Be careful to put the flies out of their misery as quickly as possible. Do not be tempted to follow such recommendations as spraying, steeping in hot water or stoving up to 120° Fahr. It is questionable if those recommending have proof of success.

GROVER ST. OX

DAFFODIL NOTES.

The Chairman of the Daffodil Committee.—Like all of us, our chairman, Mr. E. A. Bowles, always has a more or less severe attack of yellow fever every Daffodil-time; but this spring, unfortunately for himself and for us, he has combined it with a bout of the scarlet—the real thing, I am sorry to say. Hence he is a prisoner at Myddelton House, and I fear we shall not see him in his accustomed place for another week or two. Just fancy spending a whole Daffodil season in one's bedroom!

THE NEW LEEDSII NARCISSUS ST. OLAF FOR WHICH MESSRS. BARR AND SONS RECEIVED AN AWARD OF MERIT AT THE LONDON SHOW LAST WEEK. (See page 208.)

The idea is too awful to contemplate, and yet in our chairman's case it has been a reality. I am sure there is not a single one of his colleagues who does not heartily sympathise with him in his misfortune and wish him a speedy return to the world.

Two Barnstaple Seedlings.—My wanderings this year led me to both Barnstaple (Devon Show) and Truro (Cornwall Show). At the former I thought Mr. F. Batson of Beaworthy had a good seedling in Melpomene, a bicolor Barri, in shape rather like *Cresus*. The pale orange cup and the

ivory white perianth harmonised very well and gave a nice bloom. Size, $3\frac{1}{2}$ inches by half an inch by $1\frac{1}{4}$ inches. Ionia was another good seedling, shown by Miss Ida Pope of King's Norton. It is after the style of Albatross, but with a flatter and more expanded cup and a very pale canary perianth, overlapping and of good texture. Size, $3\frac{1}{2}$ inches by half an inch by $1\frac{1}{4}$ inches.

Truro Show.—Truro and J. C. and P. D. Williams are inseparable. Here these famous champions of the Daffodil show meet in friendly combat every year. Their exhibits are always worth seeing, and this year was no exception. I spotted a very fine Poet in "Mr. J. C.'s." I have since learnt that our great Poet-maker considers it to be one of the *very very* best he has ever raised. The same variety figured on Messrs. Barr's stand at the London show last week, where it gained an award of merit under the name of *Cardmon*. Awards of merit were given to *Venus*, an excellent Giant Leedsii of a good class for shows, and also to *Silver Penny* (Martin). In days not so long ago it would have been called a bicolor *Engleheartii*. The big, flat eye was of a distinct tone of deep yellow, and the whole flower reminded me of Mr. W. T. Ware's very pretty *Princess Alice*, which is described by the vendor as "practically a white form of *Princess Mary* with a splendid constitution."

The Royal Horticultural Society's Daffodil Show.

—"London," as we are beginning to call this show for short, was a great gathering of the class. All sorts and conditions of flowers were to be seen in the hall. Mr. Stocks from Darlington must have given the merodons a short respite, for he had left his nets at home and brought some flowers. Then there was that keen amateur, Mr. Morton, who, I believe, holds the money-bags of the National Hardy Plant Society. His exhibits were many and also his prizes. Then, again, there were the *White Lady* and the *White Gentleman*—more famous, perhaps, in the Rose world than in ours—with much nice stuff. Lastly, but not inclusively, there were *Parson Buncombe* from Devon with good examples of the grand white trumpet *Sibyl Forster* and *Red Wing*, the reddest thing out in perianths; *Canon Fowler*, Mr. Mallender from Strubby (a seedling-raiser of much merit), Mr. Lower from Mid-Wales, Mr. T. Batson, Mr. Cranfield, Mr. Staffurth, Messrs. Cartwright and Goodwin, Mr. Watts, Mr. Bourne, Mr. P. D. Williams, Mr. Crosfield and Mr. Wilson, the coning man, a description which I use with deliberate intent of one whom everyone thinks has already come—but "wait and see."

When our present King was Prince of Wales he made his famous tour of the Empire and recorded

his impressions in the now celebrated phrase, "Wake up!" The fascination of the Daffodil is great. Yearly it attracts an increasing number of devotees. It is as if a stone had been dropped in a still pool and the expanding ripples had just touched our big, big firms Sutton's with their own seedlings! Carter's with quite a lot of good new things, of which perhaps Dazzler, a magnificent vase flower, was the pick! Veitch's, not to be left behind, had an orthodox stage full of good old favourites and new leaven. These signs are striking. So, too, but in another way, were the vast number of new seedlings that were everywhere to be seen. Someone asked me what would happen if they were all to be grown on into stocks. "Only one thing," I said; "apply to the new Chinese Parliament for a leave of their country." But this will not come to pass. There will be a great massacre of the innocents, and practical business men will find, I expect, their goose with the golden egg in having and holding large stocks of the precise things the public is sure to want and which it will have. What those varieties will be is the question of questions to the up-to-date Daffodil-grower Mr. Ware, for example, acquired Horace. I have heard it said that he looks upon his possession as a certain yearly income for many years. I feel sure he is right. Another everyone's flower is White Lady, another is Lucifer, another is Aspasia, another is Olympia. To return to the show, of which a fuller description will be given next week, I feel I must, in response to many solicitations, lodge a protest here to the policy of the Council in allowing the Royal Horticultural Society's Hall to be let immediately before such an important show as that of April 15-16. It makes one wonder whether flowers or other things are the more important in their estimation. This is a bare statement of what happened last week: Time, 5 p.m. on the day before the show. No staging whatever fixed; about two hundred and fifty vases only available and, say, 1,500 wanted; dust *ad lib*. This I myself saw on my arrival. Readers can draw their own conclusions of the amiable frame of mind of the competitors who had arrived early to try to get forward with their work, for Daffodils take a long time to put up.

A Daffodil Year Book.—This is taking shape. The Narcissus committee have offered me the position of Editor, and I have accepted the same. I hope I may be able to turn out a book which will not disappoint the expectations of those who have waited for such a volume so long. More particulars concerning this will be forthcoming in due course.

JOSEPH JACOB.

[We have made enquiries respecting the arrangements at the Royal Horticultural Society's Hall on Monday last, and find that the trouble referred to by Mr. Jacob was in a large measure due to the illness of the superintendent, Mr. S. T. Wright, who was unable to be present on either the Monday, Tuesday or Wednesday.—Ed.]

CULTURAL HINTS ON NEW AND RARE PLANTS.

TREES AND SHRUBS.

(Continued from page 99.)

Ailantus vilmoriniana.—An ornamental tree allied to the well-known Tree of Heaven (*A. glandulosa*), from which it differs by having spiny stems and rose-coloured stalks to the leaves. It succeeds in loamy soil, and requires a position exposed to full sun, where the wood can become well ripened, for during its early life the plant is a little tender. Usually grafted upon stocks of *A. glandulosa*, it might be increased by root-cuttings once own-root plants were obtained.

Robinia Kelseyi.—The flowers of this are quite as beautiful as those of the Rose Acacia (*R. hispida*) and the same colour, while the species has the advantage of forming a larger plant and producing seeds, whereas seeds cannot be obtained from *R. hispida*.

THE BAMBOO GARDEN.

THE latter half of April and during May is an important time in the Bamboo garden, for during that period any necessary alterations may be carried out most satisfactorily, as Bamboos are then in the best condition for transplanting. It is also the best time for pruning, for although some people trouble little about this work, Bamboos which are regularly pruned have a great advantage over those which are left untouched.

Transplanting.—The time to begin dividing and transplanting the clumps varies according to the season, but a good guide is the condition of the new shoots. When these are from 2 inches to 3 inches long and new leaves are bursting on the older branches is the proper time to begin. Bamboos are not very fastidious regarding soil, for they thrive well in light, medium and heavy loam; but they must be planted in a position

HARDY BAMBOOS IN THE BOTANIC GARDENS AT CAMBRIDGE.

where the ground is never likely to become dry, or where plenty of water can be provided during dry weather. At planting-time it is a good plan to place a little leaf-mould among the soil which comes in immediate contact with the roots, while a little distance away well-rotted manure may be mixed with the soil. A good watering should follow transplanting, and both newly-planted and established clumps are benefited by a mulch of rotten manure and leaves applied in May. Wherever a good force of water is obtainable, it is an excellent plan to give the plants a thorough washing overhead several times a year, and particularly before and after pruning. This is specially needful in the case of plants growing in the vicinity of towns, where dirt collects about the leaves and branches.

Leptospermum scoparium Nichollii.—Many people voted this to be the most beautiful new plant shown at the International Exhibition held in London last year. It is an erect shrub, and has beautiful dark red flowers instead of the familiar white of the typical *L. scoparium*. In the South-West Counties it may be grown out of doors in ordinary garden soil like any other shrub, but in a colder climate a cool greenhouse is required. When new soil is provided, equal parts of fibrous peat and loam may be given with a fair proportion of silver sand.

(To be continued.)

Bamboos are usually increased by dividing old clumps into small pieces, potting them up, and standing them in a moist and warm greenhouse until growth recommences; but whenever it is

possible to obtain seeds of any species, it is very much better to raise plants from them than to propagate in any other way. As is well known, many Bamboos have flowered and died within the last few years. Some people have an idea that a plant which has flowered can be coaxed back to life; but if such a thing happens it is very rare, and the owner of a flowering plant would be well advised to keep a sharp look-out for seeds, for, once he obtains seedlings, he is safe for many years, as it is doubtful whether a seedling will bloom before it is thirty years of age; whereas a plant obtained by the division of an old stock plant may blossom and die within a year or two.

Varieties.—Over thirty different kinds of Bamboos have been introduced which are hardy in all except the coldest parts of the British Isles, providing a sheltered position is accorded them. Among the Arundinarias the following deserve special attention: *A. anceps*.—A Chinese plant growing from 7 feet to 9 feet high, with slender,

plant seen in the illustration on page 205 is this species. In size of leaf it is only surpassed by one other hardy Bamboo, that being the Chinese and Japanese *Bambusa tessellata*, which, although only attaining a height of about three feet, often produces leaves which exceed a foot in length. Perhaps the hardest of all Bamboos is *A. japonica*. It is often found in old gardens forming dense clumps 12 feet to 15 feet high and as far across. The dark green leaves are from 6 inches to 8 inches long. *A. nitida* is perhaps the daintiest of all Bamboos, its graceful, arching branches being clothed with small, elegant, bright green leaves. It grows from 6 feet to 9 feet high. The sturdiest of the Arundinarias is *A. Sinensis*, a Chinese species, which grows 18 feet high and forms wide-spreading clumps. As a contrast to this we find the Japanese *A. pygmaea*, which scarcely grows 1 foot high. It is useful for forming large masses by the water-side. More tender than the foregoing kinds are *A. falcata*, *A. Falconeri*,

SAXIFRAGA MARGINATA, A BEAUTIFUL ROCKFOIL FOR THE ALPINE-HOUSE OR ROCK GARDEN.

wand-like shoots clothed with dainty, bright green leaves. *A. auricoma*.—A Japanese species which attains a height of from 3 feet to 4 feet. It is of dense habit, produces slender branches and has golden-variegated foliage. *A. Fortunei*.—Although this grows but a couple of feet high, it is very popular on account of its silver-variegated foliage. The Japanese *A. Hindsi* is an erect-growing plant 10 feet to 15 feet high, of rather coarse habit. It is surpassed in beauty by its narrow-leaved variety *graminea*, which, though quite as tall, is of better habit and more leafy. *A. humilis* and *A. chrysantha* are two dwarf-growing plants which attain a height of from 3 feet to 4 feet; both form rather dense masses. *A. Kumasasa* is better known in most gardens under the name of *Bambusa palmata*. It is of very distinct appearance, for it forms a wide-spreading mass 6 feet to 8 feet high, clothed with leaves 8 inches to 9 inches long and 2 inches to 3 inches wide. The wide-leaved

A. intermedia, *A. hookeriana*, *A. nobilis* and *A. racemosa*, all large-growing species suitable for a mild climate.

The Phyllostachys include such graceful plants as *P. aurea*, *P. flexuosa*, *P. Henonis*, *P. mitis*, *P. nigra*, *P. sulphurea* and *P. viridi-glaucescens*, all tall-growing plants, which form fine clumps with elegant branches. But perhaps the finest of all hardy Bamboos is found in *P. fastuosa*. Of more erect habit than the majority of the Phyllostachys, it grows 18 feet or 20 feet high, with stout branches clothed with showy, deep green leaves, which keep their colour later in spring than those of any other hardy Bamboo. A few species only of *Bambusa* are grown. One, *B. tessellata*, has already been mentioned. *B. angustifolia* and *B. Nagashima* are small-growing kinds, while *B. quadrangularis* is remarkable for its four-angled stems. It is only suitable for the warmer parts of the country. W. D.

ROCK AND WATER GARDEN.

SAXIFRAGA MARGINATA.

AMONG the earlier-flowering members of the Rockfoil family *Saxifraga marginata* takes a foremost position. Its large trusses of pure white flowers are very charming during the end of March and the beginning of April, either grown in pans in a cold frame for use in the alpine-house or perched on a rocky ledge in the rock garden. In the shelter which is afforded by the former mode of cultivation the flowers are seen to the best advantage, unaffected by the weather, which is often detrimental to plants flowering at this early period of the year. Nevertheless, a group of this Rockfoil suitably planted in well-drained, gritty soil in a sunny, sheltered position in the rock garden, when in flower, is very attractive. The flowers are of greater substance than many other members of the Kabschia group, to which this species belongs. This group consists of about eighteen species of close-growing, tufted plants with small rosettes of leaves, which are pitted, and secrete lime along the margins. They are mostly natives of the dry, calcareous mountains of Southern Europe. *S. marginata* is a native of the Abruzzi in Italy, and is also said to be found on Mount Taygetus in Greece. The latter probably is *S. Boryi*, a distinct plant, but which is sometimes given as synonymous with the Italian plant. In the production of the numerous hybrids which have appeared in our gardens during recent years, *S. marginata* has played a prominent part as a parent. Of these the best is *S. Borisii* (*marginata* × *Ferdinand-Coburgi*), a handsome plant of free-growing habit with large trusses of rich yellow flowers on erect stems 3 inches high. It is one of the best of the later yellow kinds. *S. Obristii* (*bursariana* × *marginata*) partakes more of the habit of the former parent in foliage, but has pure white flowers of greater substance like the latter. All three are of easy cultivation, their main requirements being ample drainage and gritty soil that does not get too dry in summer. They may be propagated by means of division in spring after flowering, or by cuttings in summer. W. L.

COLOURED PLATE.

PLATE 1470

THE HARDY NYMPHÆAS OR WATER LILIES.

(Continued from page 182.)

Varieties.—We have now, thanks in a great measure to the untiring efforts of the late M. B. Latour-Marliac, and more recently to his son and successor, a marvellous selection of hybrids, and that in surprising variety, both as it pertains to colour, to vigour and to freedom of growth. There is an abundant choice now in whites, in pale pinks, in deeper pinks and rose colours, in reds, in crimsons of various shades, and in yellows also. Of these some of the more recently-raised hybrids are most remarkable, both in purity of colouring, in size of flowers, in the breadth and substance of the petals, and in their floriferousness. To look at some of these later hybrids when in their full beauty is but to admire them, and even to wonder how they have been evolved out of those we knew, say, ten years back. In more than one instance the season of flowering has been extended, both

THREE GOOD WATER-LILIES:

- White: "Gladstoneana."
- Pink: "Mrs. Richmond."
- Crimson: "Gloriosa."

early and late. Some of the best of these newer hybrids, so far as I have been able to note them, are: Whites—*N. virginialis* (Latour-Marliac, 1910), which is very free-flowering, with flowers of the largest size, the petals being shell-shaped and of the purest white. The sepals are very slightly tinged with faint rose colour at the base, the stamens being yellow. With us it is the earliest of all to flower, as well as one of the very latest. Its description acent this by Latour-Marliac is "précoce et tardive," and it well explains this characteristic. The foliage is large, and has a faint tinge of purple therein. Of pale pinks, *N. Mrs. Richmond* (Latour-Marliac, 1910) is, in my opinion, the most lovely flower imaginable in this the softest of colours. Of it we have had flowers nearly, or quite, nine inches in diameter. The petals are broad and massive, the stamens yellow. The flowers, when fully expanded, are a lovely sight. Its vigour, too, is all that one can desire. It has flowered now for two seasons with us, and is gaining in vigour. (See coloured illustration.) *N. formosa* (Latour-Marliac, 1909) is somewhat similar to the preceding in its colouring, but deepening towards the centre. The petals in this instance, I have noted, are distinctly margined with pale pink (quite a peevish edge); the growth, also, of this hybrid is very vigorous. The stamens are yellow and the flowers of the largest size. *N. somptuosa* (Latour-Marliac, 1909), in which the rose colour is slightly more intensified, is another acquisition. In form it very much resembles *N. Laydekeri rosea*, having that incurved shape of the petals. The stamens are of a deep orange tint. I should add that the petals are more numerous than in many of these hybrids; in addition, also, it is fragrant. The growth is both dense and vigorous. *N. Newton* (Latour-Marliac, 1910) is, not strictly speaking, a pink colour, having a suffusion of vermillion, though of a pale shade. Its flowers are stellate in form and stand distinctly above the foliage; the stamens are orange yellow. *N. Colossea* (Latour-Marliac, 1909) is not, strictly speaking, a new variety; nevertheless, I do not think it is sufficiently known. It produces the largest flowers of any with us, and is best described as being a glorified *N. Marliacea rosea*. I have noted its flowers in the height of the season as much as 10 inches in diameter. It flowers both early and late; the foliage, also, is of the largest size. The parentage of *N. Colossea* is given as being *N. maxima alba* × *N. gloriosa*. Of crimsons, the finest, in my opinion, is *N. Escarboucle* (Latour-Marliac, 1909). In its colouring it is almost unique. We have none that approaches it in intensity of colour, which is described as a uniform vermillion red. So far I do not think it is found in many collections. The stamens are of a deep vermillion red, very distinct. *N. Meteor* (Latour-Marliac, 1909) is somewhat after the preceding,

but not so brilliant in colour. The petals are streaked with white, but not regularly; the sepals are lined with red, and the stamens of a golden yellow shade. *N. Attraction* (Latour-Marliac, 1910) resembles somewhat that well-known hybrid *N. atropurpurea*. It is, however, much brighter, and cannot be considered as of the same colour, which in this instance is a deep bright purplish crimson with venations of almond white; the stamens are of a deep mahogany tint. *N. Conqueror* (Latour-Marliac, 1910) has very fine and distinct flowers of the largest size, bright red in colour, with white veinings occasionally, the colouring being deeper upon the convex side of the petals; the stamens in this instance are orange

du Temple-sur-Loire, *N. Marliac* (Laplace), *N. Piccola* and *N. Sirius*. These will not be distributed until they have been exhibited in Paris when in flower.

There are two other varieties which make up the trio in the coloured plate of this issue. One is *N. gloriosa* (Latour-Marliac, 1896), the parentage of which is given as *N. Laydekeri* × *N. caroliniana*. In its colour and form there is not one that is finer. The colour needs no description here, but as regards its form it should be noted that *N. gloriosa* has, in every perfect flower, five sepals. It is the first hybrid in which I have noted this tendency. This causes the flower to open more fully, and to show itself to the best advantage in so doing. *N. gladstoneana* is given in *L. Jardin* as *N. tuberosa gladstoneana*, and the parentage as *N. tuberosa* × *N. alba* (Richardson, 1897). It is a most remarkable hybrid and one of the finest whites in cultivation, with no semblance whatever of pink in the petals; instead of which the few touches of palest green add to its beauty. The flowers are somewhat after *N. tuberosa* in form, being disposed to curve as in that species. The flowers are of the largest size, while the leaves are larger than any other Water Lily with which I am acquainted. I suppose this latter feature is why the moorland cottentines select it upon which to make their nests.

JAMES HUDSON, V.M.H.,
Gunnorsbury House Gardens, Acton.
(To be continued.)

LYCASTE SKINNERI, A BEAUTIFUL YET EASILY-GROWN ORCHID FOR THE AMATEUR'S GREENHOUSE.

yellow. The flowers possess great substance in addition. The foregoing are ten of the finest of the newer hybrids, so far as I have been able to prove them. They are all distinct from the older varieties, and every one possesses the essential of a vigorous growth.

One other new hybrid, with flowers of a stellate form, is *N. James Hudson* (Latour-Marliac, 1912). Of this I hope to report on another occasion. So far I have not had a good flower of which I could form a correct opinion. Others that are to be sent out this season bid fair to be quite distinct. Of these I will only give the names of four that should prove acquisitions. These are *N. Gloire*

lip in some instances is distinctly marked with crimson. It is an ideal plant for an amateur to choose. The amount of variation to be found in this species makes it an interesting subject to buy freshly imported. It is free-flowering, of easy culture, and the flowers remain in perfection for several weeks. Such attributes are not always to be found wrapped up in a single species. For the grower who desires other representatives of this genus, I would suggest the yellow *aromatica* and its closely-allied neighbour *orientalis*.

Cultural Notes.—At this period of the year *L. Skinneri* and its numerous varieties will be past the flowering stage, and the season's growth

GREENHOUSE.

EASILY-GROWN ORCHIDS FOR THE AMATEUR.

Lycastes.—The genus *Lycaste* contains several plants which are largely grown for their useful and decorative value. The most popular is *L. Skinneri*, from 12 inches to 24 inches in height, while the fleshy, handsome flowers are usually a beautiful shade of rose. These are produced from the base of the last-made pseudo-bulb, being borne singly upon erect scapes. There are various forms of *L. Skinneri*, such as *alba*, a chaste variety with pure white blooms, and others with paler and deeper shades of rose, while the

will soon begin. When this is 2 inches or 3 inches high and a batch of roots are seen pushing out from the base, any necessary repotting may be carried out; but it should be borne in mind that annual disturbance is not advisable, every second or third year being sufficient if the watering is properly carried out. Ordinary flower-pots or fairly deep pans prove ideal receptacles, which ought to be filled one-third of their depth with drainage, over which is laid a thin layer of fibrous loam. A suitable rooting medium consists of good loam, fibrous peat and *Osmunda* fibre in equal parts, and to every bushel of the mixture add a 7-inch potful of finely-crushed potsherds. Having selected a plant requiring fresh rooting material, it will be found necessary to remove a large portion of the old soil, cutting away any decayed roots and all the useless back pseudo-bulbs, three behind each growing point being ample. When the plant is thus prepared, the old bulbs should be placed close to the rim of the pot, which will bring the new shoot near the centre, and so leave space for future development. Work the soil well between the roots, and press it moderately firm as the operation proceeds; but it must not be brought above the rim, as *Lycastes* enjoy a fair quantity of water throughout their growing period. A light position in the cool or intermediate house will suit them throughout the year. After repotting, keep the plants on the dry side till the roots are seen creeping to the edge, when the compost must be kept moist till the pseudo-bulb is fully matured; but afterwards less moisture is needed until the flower-scapes appear. As *Lycastes* come from fairly high altitudes, fresh air is an important factor in their successful cultivation; but in this country it must always be admitted with discretion, and strong currents of air passing over the plants cannot be tolerated. The chief subject of this note, viz., *L. Skinneri*, may be termed semi-deciduous, so no anxiety need be felt by any amateur when he notices some of the leaves showing signs of decay.

SWEET-SCENTED GREENHOUSE RHODODENDRONS.

A DELICIOUS fragrance is a valuable asset in flowers of any kind, and this feature is very pronounced in the case of some of the greenhouse *Rhododendrons*, now in flower. Many of these are garden forms, and in nearly all cases they inherit the greater part of their fragrance from the Himalayan *R. Edgeworthii*, in which this feature is largely developed. This species, which is among the most tender of the Himalayan kinds, is very distinct from any of the others, the somewhat trailing branches being, especially when young, of a very woolly character, which feature also extends to the under sides of the leaves. In a state of

Nature this often occurs as an epiphyte, finding its rooting medium in the vegetable *débris* collected in the forks of trees. The flowers, which are borne few in number in a loose head, are pure white, except for a yellow stain on the upper part of the interior. As with epiphytes in general, this *Rhododendron* dislikes a large mass of soil around the roots. Among the older and well-known

PRIMULA MAXIMOWICZII, A NEW SPECIES WITH RED FLOWERS FROM NORTHERN CHINA.

garden forms that owe the greater part of their fragrance to *R. Edgeworthii* may be named *Princess Alice*, *sesterianum*, *fragrantissimum* and *Lady Alice Fitzwilliam*. An exceedingly free-flowering and sweet-scented race of *Rhododendrons* was raised by the late Mr. Isaac Davis of Ormskirk, noted as the original raiser of *Rhododendron præcox*. From the intercrossing of *R. Edgeworthii* and *R. multiflorum* (a garden form) Mr. Davis raised the following varieties, all of which are remarkable for their perfume: *Countess of Derby*, *Countess of Selton*, *Duchess of Sutherland*, *Lady Skelmersdale* and *Mrs. James Shawe*. Up to the time of the death of Mr. Davis and the dispersal of his collection one could always purchase delightful little flowering plants of these varieties, but they are now very difficult to obtain from nurseries. This is a great pity, as most of them flower well in a smaller state than many other of the *Edgeworthii* hybrids. H. P.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATE.

Narcissus Mrs. Ernst H. Krelage.—A handsome white Ajax (trumpet) Daffodil, than which nothing so fine has been seen for some time. A well-high faultless flower of large size, even balance, lustrous white throughout save for the lemon yellow reflexing rim of the crown. From Messrs. Krelage and Son, Haarlem, Holland.

AWARDS OF MERIT.

Narcissus Europa.—This has a creamy white perianth and lemon yellow expanding crown. The flower is of exceptional size. From Messrs. W. T. Ware, Limited, Bath.

Narcissus Caedmon.—A handsome Poeticus variety of exceptional size and purity, the slightly-incurving segments of the perianth suggestive of the influence of *recurvus* or one of its kin. The red-rimmed, green-eyed crown renders the flower quite conspicuous. Shown by Messrs. Barr.

Narcissus St. Olaf.—A Leedsii form of almost opaque whiteness. Apart from its good balance, its substance and firmness of texture appeal to one at a glance. An all-white flower save for a touch of palest lemon in the crown. Exhibited by Messrs. Barr and Sons, Covent Garden, W.C. See illustration on page 204.

Primula Maximowiczii.—A remarkable novelty from North China and an acquisition *withal*. In the rosette of lanceolate leaves there is more than a suggestion of *P. rosea*, the stout scape rising therefrom to the height of 1 foot or thereabouts. Flowers cardinal red, drooping, with slightly-reflexing lobes, pedicellate, and produced in whorls, those on the lowest whorl most numerously disposed.

Androsace tibeticum.—The habit of the plant is somewhat similar to *A. Chumbyii*; the individual flowers are larger, however, and in their pink and white garb quite distinct. A beautiful alpine.

Hippeastrum (Amaryllis) Eurasian.—A handsome, well-formed

flower of good substance and rich ruby crimson colour. The plant is of dwarf habit. The three foregoing novelties were shown by Messrs. James Veitch and Sons, Limited, Chelsea.

Auricula Suffragette.—The finely-formed, large, circular flowers are coloured a rich golden yellow, and have a well-defined white centre.

Primula viscosa Beauty (*P. viscosa* × *Auricula Innocence*).—The *Auricula* influence is not marked, the hybrid presenting all the characteristics of a good alpine Primrose. The predominant colour is violet purple; the eye is white. These were from Mr. James Douglas, Great Bookham, Surrey.

Helichrysum bellidoides.—An alpine "Everlasting" with white flower-heads abundantly produced on 3-inch-high, subsequently trailing plants. A novelty and a desirable plant *withal*. It is quite hardy, flowering naturally in May and June. From Mr. H. Hemsley, Crawley, Sussex.

GARDENING FOR BEGINNERS.

HOW TO GROW GOOD RUNNER BEANS.

AMONG amateurs there are few more popular or highly-appreciated vegetables than well-grown Runner Beans. Whether they are required solely for the dining-table or for the additional purpose of exhibiting, good fleshy, brittle pods are indispensable during the early autumn, when the Green Peas are on the wane. In not a few districts amateurs vie with each other in cultivating these Beans to well-nigh perfection; and it is with a view to providing the beginner in vegetable culture with some hints on growing these Beans that we publish this article.

Preparation of the Soil.—

As the plants are voracious feeders and appreciate a cool, moist root-run, no pains should be spared in providing them with these essentials. The stout roots also penetrate the soil to a considerable depth, so that it well repays to break it up at least two spits deep. With the lower spit plenty of partially-decayed manure should be mixed. If the soil contains a preponderance of sand, cow or pig manure is best; but if clay is the principal element, that from horses is preferable, though in many cases the beginner has to use the best that is obtainable. With the top spit it is a good plan to mix some superphosphate or steamed bone-meal, a good handful of either to each yard run of row. In addition, if the soil is very stiff clay, some burnt earth, old potting soil, road scrapings from country roads, or, indeed, anything of a porous nature that will tend to render it more friable may be added, taking care to mix it well with the soil. If the ground can be prepared at once, it will be in good condition for sowing the seeds when the time comes.

Sowing the Seeds.—The time usually selected for sowing Runner Beans in the London district is the second week in May. The plants are very easily injured by frost; hence it is inadvisable to sow earlier than the time named. A system that is much in vogue in cold districts and where early crops are desired is to sow the seeds in pots or deep boxes and bring the plants along in a cold frame, transplanting them to their permanent quarters about the last week in May. Where such a system is adopted, it is highly essential that the plants be grown on as sturdily as possible, any attempt at forcing growth in a high

temperature resulting in weak, attenuated plants that will never give good results. In sowing outdoors we always like to make a trench about three inches deep and fifteen inches wide. This facilitates watering during hot weather. The seeds should be sown in two rows in the trench, placing them 8 inches apart in the rows and leaving the rows about ten inches

apart, but the soot or lime must not touch the foliage. As soon as the plants begin to run, stout stakes, twine, or coarse netting must be placed for them to climb. Six feet is a reasonable height for the supports, though the plants will climb nearly twice that height if supports are available. The system of topping Runner Beans, as is done in the market gardens, is not one that

we would advocate for garden cultivation; wherever a pod rests on the soil its flavour is impaired. Besides, a well-supported row of Runner Beans makes an excellent screen in the garden, a point that ought not to be lost sight of in selecting the site. During hot weather, and particularly when the plants commence to flower, copious supplies of water must be afforded, and once a week should be supplemented with weak liquid manure. In addition, an overhead syringing with clean water will prove highly beneficial and keep that most dreaded of all pests, red spider, at bay. When the plants reach the tops of their supports, the growing point of each should be nipped out, an operation that may have to be repeated several times.

Some Good Varieties.—There are a number of good varieties now obtainable, preference being given to those with long, fleshy pods. A good type of this section is shown in the accompanying illustration, the variety being Carter's Red Giant. With ordinary cultivation, on the lines suggested above, this variety last year produced a heavy crop of pods, most of which measured from 10 inches to 12 inches long. Hackwood Park Success, Sutton's Prizewinner and Best of All, Mammoth White, Painted Lady and Webb's New Exhibition are all varieties that one can thoroughly recommend. H.

RUNNER BEAN RED GIANT, A LONG-PODDED VARIETY OF HIGH QUALITY.

temperature resulting in weak, attenuated plants that will never give good results. In sowing outdoors we always like to make a trench about three inches deep and fifteen inches wide. This facilitates watering during hot weather. The seeds should be sown in two rows in the trench, placing them 8 inches apart in the rows and leaving the rows about ten inches

apart, but the soot or lime must not touch the foliage. As soon as the plants begin to run, stout stakes, twine, or coarse netting must be placed for them to climb. Six feet is a reasonable height for the supports, though the plants will climb nearly twice that height if supports are available. The system of topping Runner Beans, as is done in the market gardens, is not one that

we would advocate for garden cultivation; wherever a pod rests on the soil its flavour is impaired. In addition, an overhead syringing with clean water will prove highly beneficial and keep that most dreaded of all pests, red spider, at bay. When the plants reach the tops of their supports, the growing point of each should be nipped out, an operation that may have to be repeated several times.

SOWING MIGNONETTE.

We take this opportunity of reminding readers that this sweet-scented plant may still be sown to prolong the supply of bloom. There is much to be said in favour of growing Mignonette, as well as Violas, as a groundwork to beds of

Roses, although the very keen rosarian might raise an objection to this procedure. Mignonette is a very accommodating subject, and may be used to furnish any odd corner in the garden. It seems hardly necessary to remind readers that slugs are very partial to the Mignonette in its seedling stage. These pests may be kept at bay by occasionally dusting soot around the seedlings.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Violets.—There are various systems employed for raising a stock of Violets for flowering during the winter and spring, but the simplest method is to plant out the young rooted side shoots on ground that has been well prepared some little time beforehand; this should be done as soon as the crop of bloom is over in the frames.

Cuttings put in during the autumn in a frame or under hand-lights should also be planted in the open ground at once, giving a fair distance between the plants. These latter will not need so much attention, should the weather be warm, as the first mentioned, owing to their being better rooted, and they certainly make larger plants.

Violas.—Named varieties propagated in the autumn should now be removed to their flowering quarters, either in the borders or, it may be, to furnish the beds under Roses. Though I do not recommend this for the sake of the Roses, one is obliged to admit that the Violas in many instances make a good show in such a position.

Plants for Summer Bedding.—Where Violas are intended to be used as a groundwork to other plants for summer bedding, they may have to remain some three or four weeks in the stock beds. Such plants should have the blooms removed, and when the young plants are inclined to be rather leggy, they may be pinched to induce a more bushy habit of growth. Needless to add, wherever Violas are wanted for a summer show here in the South, a fairly cool and moist position must be selected.

Labelling Plants.—No matter how careful one is to try to keep labels in their proper positions, it often happens that some get displaced or the writing obliterated, so that it is advisable to go round the borders as the various classes of plants come into bloom, labelling those that require it.

Plants Under Glass.

The Conservatory.—Just now the conservatory should be very gay with such plants as Cineraria, Schizanthus, Amaryllis and Calceolaria, and to prolong their flowering period a fair amount of shade must be given during bright sunlight.

Climbing Plants, such as Fuchsias, Habrothamnus, Tacsonias, Abutilons and Heliotropes, to be planted out later should be kept tied and thinned, according to the space they have to cover, and if on the roof, must be kept very carefully thinned, or plants underneath are very apt to suffer.

Primulas.—For an early batch of plants seeds may now be sown of *P. sinensis*, *P. stellata*, *P. obconica* and *P. malacoides*. From such a sowing they should flower in the autumn, but for spring blooming sowing a month or six weeks hence should be quite soon enough.

Maidenhair Ferns.—Batches of these that have not been repotted and that are growing freely should be fed fairly regularly either with liquid manure or artificial manure, giving this latter about once a week in small doses. If required for conservatory work, too much moisture must not be given, or the fronds will become soft, and there is danger of the small inside fronds damping where the plants are at all dense.

The Vegetable Garden.

Globe Artichokes.—To keep up the stock of this vegetable in a healthy condition it is advisable to break up and replant a portion of it each season, and the present is a very suitable time to do it. Suckers from the old plants should be planted in a deeply-cultivated and manured piece of ground in rows about four feet apart, allowing at least a yard between the plants; and, should the weather become dry soon after planting, it may be necessary to give a good watering to prevent undue flagging.

Asparagus.—This delicious vegetable should now be giving good strong heads, and whenever possible it is advisable to break these off rather than to cut them, as many young heads are often injured below the ground. Keep the surface of the soil clear of weeds, and give occasional dressings of Asparagus manure during showery weather.

Chicory.—This useful winter salad plant should be sown during the next few days, preferably as a continuation to the bed of Salsify and Scorzonera, and at about the same distance apart, thinning the plants to about nine inches apart when they are large enough to withstand the ravages of slugs.

Brassicas.—Another sowing of Brassicas should now be made, chiefly of late varieties of Kale, Coleworts, Savoys and Broccoli. These late batches of plants often prove more useful than the earlier ones, especially when they have to be planted after the ground is cleared of some of the early crops of Peas and other vegetables.

Fruits Under Glass.

Pot Vines.—The fruit on the earliest pot Vines will shortly commence colouring, and to secure evenness in colouring the plants should be carefully turned round occasionally; this, of course, if they are not allowed to root into the border. Water must not be stinted, though as colouring progresses rather less may be used about the house, and more ventilation may be given, though draughts from the front ventilators must be avoided.

Permanent Houses must be very carefully looked after in respect to ventilation, especially where the fruit is stoning. If a little air is left on all night, there is not much danger from scalding; but if shut up close and the house gets the full benefit of early morning sun, unless air is put on before the temperature rises unduly there is considerable danger, and many good bunches may be spoilt.

Hardy Fruits.

Peaches on Walls.—As soon as the shoots are forward enough, thinning should be commenced. It is not advisable to do this all at once—just a few growths from each shoot or branch, commencing by taking off the back shoots and a few on the under side, always bearing in mind that it is the basal shoots and perhaps one or two on the upper sides of the branches that are required to furnish the next season's fruiting wood. Go over the trees two or three times before reducing the shoots to the desired number.

THOMAS SIEVENSON,

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Primula Sieboldii.—Those who have only seen individual plants or small patches of this lovely Primula can have no idea of the effect produced by masses of it. Here we have several beds in various shades—white, lilac and crimson. I would strongly recommend its extended cultivation. Give it a cool bottom and a light, rich soil, and it will increase rapidly by means of its creeping roots.

Perpetual-Flowering Carnations.—This accommodating class of Carnations has not been much drawn upon for the flower garden in Scotland yet, I believe; but I know one garden where the plants have been tried with success for the past two seasons. Those who have some year old plants of varieties like Britannia and Mrs. Burnett might do worse than try them in the open, and the present is a good time to plant.

Planting Gladioli.—Named florists' varieties which have been forwarded in pots should now be planted out. As indicated some weeks ago, Gladioli—this class especially—require liberal cultivation. A fairly rich, rather light, deeply-wrought soil is what they want, and, like all bulbous plants, they are impatient of stagnant moisture.

Dahlias.—Whether old tubers or young plants, these must now be got into cold frames and gradually hardened off. Give old tubers plenty of flaky leaf-mould to root in.

The Rose Garden.

Aphis.—This pest, like the poor, is always with us; happily, however, it is not difficult to deal with. Quassia Chips Extract, N.L. All Liquid Insecticide and Gishurst Compound are all effectual remedies; but the same result can be obtained by syringing with a solution of soft soap and water, at the rate of a good handful of soft

soap to a bucketful of water. If the operation is repeated with clean water two hours later, no traces of the soft soap will remain.

Aerating the Soil.—This is a very important point in Rose cultivation, and the soil should be stirred at least once a fortnight by means of the Dutch hoe.

Plants Under Glass.

Begonias.—Those of the tuberous section will now be ready for their final shift, and the size of the pot must be regulated by the age and vigour of the plant. Afford ample drainage, use a fairly rich, porous soil, and do not pot too firmly. These plants resent coddling on the one hand and cold draughts on the other; they enjoy comparative shade.

Herbaceous Calceolarias.—As the flower-stems develop, staking must be attended to, using Bamboo tips or some other slender form of stake. As the blooms develop they must be shaded from bright sunshine, or the flowering period will be curtailed. If there is the least appearance of aphid, vaporise now.

Sowing Cinerarias.—The main batch of these should now be sown in a cool frame. Water the soil in the box or pan two hours or so previous to sowing. Cover the seeds lightly with a little fine soil and a sheet of glass, and shade lightly till germination takes place.

Fruits Under Glass.

Orchard Fruits.—The occupants of the orchard-house will now have all set their fruits and will require close attention. Thinning the fruits should be commenced early and spread over a week or two. It is more creditable to have a fair quantity of fruits of good size and quality than to have double the quantity of small, inferior fruits. Feeding is also very important, as the tree depends largely upon the nutriment thus given. Weak and frequent doses should be the rule. Potash must be given in some form if the best results are to be obtained. One other point to be remembered is that if the soil is even once allowed to become quite dry, the damage caused to the current crop is practically irreparable.

The Hardy Fruit Garden.

Spring Frosts.—In our fickle climate frosts frequently occur about this period, especially in low-lying gardens or those a considerable distance inland. On this account many a crop of fruit has been ruined. It is worth while to take the trouble on a frosty night to throw a piece of old netting over any tree of special value, and a break of Gooseberries or Currants might be saved by running one or two nets over them.

Removing Suckers.—Plum trees have a knack of sending up suckers from the stocks, and these should be promptly removed with the hoe or knife. Gooseberries also occasionally throw up suckers, and must be similarly dealt with.

The Vegetable Garden.

Kidney Beans.—A good sowing should now be made of some reliable main crop variety, such as Canadian Wonder, and for this type of Bean the drills should be about two feet apart. A little wood-ash sown into the drills will prove beneficial.

Runner Beans.—A sowing of this useful crop should now be made. I find it a good plan to sow two drills about two and a-half feet apart, and then allow about double the distance before the next pair of drills are drawn. It is unnecessary to get in between the two closer rows.

Leeks for Exhibition.—Leeks which have been raised under glass and potted up should now be fit for planting. A trench similar to a Celery trench should be prepared for them, and it some turfy soil, such as the parings of grass edgings, is available, so much the better. A layer of well-rotted farmyard manure should be placed in the bottom of the trench, and then the trench should be partly filled in with a mixture of the turf—chopped up, of course—rotted manure and bone-meal, with a little soot. Plant in a single row at a foot apart.

Early Potatoes.—As the foliage develops, a little dry earth should be drawn up to it to protect it from late frosts. The ground between the drills should also be loosened with the digging-fork prior to earthing up the crop.

CHARLES COMFORT,

Bloomfield Gardens, Davidson's Mans, Midlothian.

THE FIFTY BEST ALPINES. THE FLOWER GARDEN.

MR. FARRER, in his selection of fifty alpines, has picked out some gems, which could only be expected of him, and he also invites other selections. I now give my selection of fifty, and, as is usual among alpine-lovers, one is sure to differ from another. In the first place, Mr. Farrer has chosen the awl-leaved setacea group of Phloxes, which are very fine, especially in a showery season, but suffer more from drought than any other rock plants that I know, and unless thoroughly watered each day when in full bloom, would be completely burnt up in a day or so if bright, sunny weather prevailed, and further South would, I should think, be a difficult plant to manage in any but a showery season. It does not winter so well as a great many other plants. Mr. Farrer has also given four Geraniums, which are very fine, but he does not mention the gem of them all, *G. tuberosum*. These different lists, with their concise cultural hints, are of the greatest assistance to those who essay to grow alpines, about the cultural requirements and value of which there is evidently some considerable diversity of opinion. It would be surprising if there was not a wide difference of opinion as to the best fifty alpines, nothing but good, however, can result from the publication of these different ideas.

SWEET PEA NOTES.

Planting Out.—Generally speaking, there is not the slightest need to urge Sweet Pea growers to get the plants into their permanent positions; on the contrary, the principal trouble is to persuade them to exercise reasonable patience in the matter; but there are always a few laggards, and it is to these that this brief paragraph is specially directed. Those who have plants still in pots or boxes in the greenhouse, frame, or standing out of doors must plant them immediately. It is, of course, most important when the plants are in pots, because they will inevitably become rootbound; and while one has not the slightest objection to shaking out the roots, one would not desire to tear them all to pieces in the process. Besides that, the roots are certain to harden, and therefore an undesirable check to progress follows upon the planting. The popular objection to sowing Sweet Peas indoors with a view to transplantation is that they cease growing entirely for some days when put in their flowering quarters; but this is not the case when proper care is taken in handling the roots and in choosing a time when the soil is in an ideal state for such an important operation. The holes must be exceptionally deep and, needless to say, the soil must be fertile.

Late Sowing.—It is not uncommon, for reasons over which the owner of a garden desiring to grow

Sweet Peas has no control, to be unable to sow under cover in the autumn or the spring, or out of doors at the middle of March, which is usually accepted as somewhere near the best time in the South of England. Someone with a mania for early sowing tells him that it is useless to start at the end of April, as the plants will never proceed so satisfactorily as to ensure a plentiful crop of good flowers. Take no notice of such a man. If it has been impossible to sow before the present date, sow as soon afterwards as can be managed. It is, of course, necessary that the soil shall be in perfect mechanical condition, and that there shall be an abundant supply of readily available food, not, for preference, in the form of natural manure near the roots. Place the seeds not less than 3 inches apart on a firm, level base, and cover the dark brown and black seeds with half an inch of mould, but simply press the white and spotted seeds into the surface. When the time arrives for thinning, remove plants as may be necessary to leave the distance 6 inches. This will not conduce to the production of blooms with stems a couple of feet in length; but that will not matter, as the object of culture is not exhibition blooms, but plenty for home decoration.

Pinching Laterals.—The man who must be there will pinch out every lateral directly he can see it, and when this is done, the next best thing is to let the plants flower, or the result will be coarseness in an unenviable degree. If blooming is permitted until a given date before a show, the tendency to grossness will have received some check, and the stems will be of splendid substance, the blooms of fine size and form and artistically set, instead of being on the floppy side and widely separated on the stalk. Some pinching of laterals is always necessary, even when the primary idea is plenty of flowers; but it should not be carried to an unreasonable extent.

Training the Plants.—The grower for exhibition shows much better judgment than the man who cultivates for immense quantities of blossoms, because the latter is usually inclined to let the plants grow anyhow and anywhere, provided they go up the supports. This is not wise. Although one must, of course, give more time to the plants when tying is done, it pays over and over again. Vigorous shoots do not always go in the direction that will favour or ensure the most gratifying results; but when the grower takes the trouble to train them, he sees to it that they go where he wants them to go. No matter whether the plants are grown to one, two, or three stems—few people let more than the last number remain nowadays—tying must be done in loose, secure ligatures, the most scrupulous care being exercised not to draw the growths in so closely that a formal appearance is given to the individual plants and to the rows.

The Gardens, Ashby St. Ledgers, Rugby.

G. F. HYLAND.

THE EDITOR'S TABLE.

Beautiful Flowers from Berkhamsted.—A box of delightful flowers, comprising Blue Primroses, *Arctotis aureola* and *Rose Fortune's* Yellow, has been sent to us by Mr. A. G. Gentle, gardener to Mrs. E. H. Demson, Little Gaddesden, Berkhamsted, Herts. The flowers reflect the highest credit upon the cultivator, while we have nothing but praise for the admirable strain of Blue Primroses that were sent. Mr. Gentle sends the following note with the flowers: "I am sending for your table a few of each of the many different

shades of Blue Primroses that are now in flower in these gardens. I also enclose a few flowers of that beautiful greenhouse plant *Arctotis aureola*, which I am surprised is not more often grown. It is free-flowering, and at this time of the year very useful for decoration, as it lasts a long time in water. The few Fortune's Yellow Roses are nearly the last. I have cut over seven hundred blooms off the one tree this year. We used to think it good to get ooo, but these last two years the number has been over seven hundred. I planted the tree about twelve years ago. I think you will agree that the colour of the Roses is very good."

Carnations from Guernsey.—Mr. C. F. A. van der Sluis, the well-known Carnation-grower of Ramec, Guernsey, sends flowers of Perpetual-flowering and Perpetual Malmaison Carnations. These include many of the best and latest varieties, and all the blooms show signs of good cultivation. The value of these flowers for cutting can scarcely be over-estimated.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

ANEMONES AND RANUNCULUSES UNDER YEW (*Miss M.*).—The plants may flower in the position once, though much would depend upon the top spread of the branches of the tree and the dryness of the situation. In any case it would not be well to plant within 6 feet of the bole of the tree, as the growth will of necessity become drawn and, of course, will favour the direction of light. If you are contemplating planting this season, the work should be done at once.

GODETIAS AND CLARKIAS (*Dr. H. S.*).—If the soil is light and well drained and the plants have responded to the earlier pricking out or transplanting, they would do so again if taken in hand early. Where the soil is sandy or stony, sowing in the open about mid-March gives excellent results. In your own case, where the soil is of a retentive nature, a good way would be to raise seedlings in boxes or pans, prick three or four into a small pot, and subsequently plant these when required. We are not sure what *Centaureas* you are referring to. The forms of *C. cyanus* are best sown in the open. Those of the Sweet Sultan class (*C. moschata*) should be sown three or four seeds in a 4-inch pot, and transplanted bodily when of sufficient size.

PENTSTEMONS AND OTHER PLANTS (*St. Mary's Church*).—The Pentstemon is a true perennial, without doubt, though the florists' varieties of it are not hardy in all districts. Those of the Gem class, Newbury Gem and others, are hardier. If you are growing the former, the best results would be secured by sowing seeds in warmth in January, or by rooting cuttings in autumn and wintering in a frame or greenhouse. Forget-me-nots, if cut back after flowering, should, with the lapse of a week or two, be divided and planted in lines. They make nice tufts for autumn planting when so treated. These things are also easily raised from seeds. The border Carnation should be layered in July. In a few instances the layered plants may be allowed to remain to flower without replanting, though this method cannot be generally recommended. Potting up the layers in September or replanting them is the best course to pursue.

THE GARDEN GENTIANELLA (*Will Bruce*).—It is difficult to lay down hard-and-fast rules in respect to this fine plant, and we know of instances where it thrives and flowers well in cool, loamy clay with little sand, in light, sandy loam, and in peaty soils. Generally speaking, it grows and flowers most freely in light, sandy loams which are deficient in lime, though it is known to do well

in limestone soils, also in light, loamy soils over sand, and in gravel. The plant rarely gives much trouble and by planting moderately small pieces in October or between that and February, success may be assured. To the light soil well-decayed leaf-mould may be added. It is important that firm planting be indulged in, and that the plant be inserted low down. In parts of Ireland the plant revels in peaty soils and the moisture-laden atmosphere. Extremes of dryness should be studiously avoided. It appears also to have a fondness for the cooling influence of old red sandstone, and some of this, if at hand, might be finely pulverised and mixed with soils of a more holding nature.

TREES AND SHRUBS.

BEAUTIFYING PARKLAND (*E. M. M.*).—The best thing to do with your park would be to introduce a number of groups of irregular shape of Gorse, Broom, Thorns, common Juniper, various species of Rosa, such as *R. canina*, *R. rubiginosa*, *R. rugosa* and *R. arvensis*, Sloe, common Berberis and Brambles, with a few groups and isolated specimens of common trees, such as Beech, Oak, Elm and Hornbeam. The remainder of the park might then be mown for hay, as at present, and pastured later on. It would be necessary to protect the shrubs and trees with low fences until they were large enough to look after themselves, both on account of hares and cattle. We do not think you would find it a satisfactory method of dealing with the park to stop mowing altogether, for the grass would become very coarse, especially if there were no animals to eat it off. By forming natural-looking groups of trees and shrubs and protecting them for a time, the park ought gradually to assume the appearance desired. Bracken may also be tried, but it is a very difficult plant to establish in many places, although such a pest elsewhere. Here and there the groups of shrubs and Bracken should be of considerable size.

THE GREENHOUSE.

UNCOMMON GREENHOUSE FLOWERS (*W. B.*).—Uncommon subjects that might suit your purpose are *Amplexicaule Enodioides*, *Clantius puniceus albus*, *Eranthis tomentosa*, *Gerbera* (new hybrids), *Tecoma Smithii* and *Rehmannia angulata* Pink Perfection.

SMILAX TURNING YELLOW (*Nit*).—There is nothing on the foliage of the Smilax to account for the yellowing except a few green flies. They do not seem to be sufficiently numerous to have caused it. There may possibly be some scale insect lower down than the pieces you send, otherwise we think the trouble is the result of some error in cultivation.

BELLADONNA LILY (*P.*).—*Amaryllis Belladonna* flowers naturally in the autumn, and then commences to grow directly afterwards. We can scarcely understand your bulbs being dormant now unless they are imported ones. The rational way to treat the *Belladonna Lily* when it is grown in pots is, as soon as the blossoms are over, to give it a good position in a frame or cool house and keep it growing during the winter. Towards the end of spring or in early summer it will go to rest, when the pot should be fully exposed to the sun and the soil kept almost dry. By the end of August or thereabouts signs of growth will be apparent, the flower-spike being the first to show, and then water must be given. As yours is still dormant, we should advise it being moderately watered, in order to start it into growth as quickly as possible. When the pots are well furnished with roots, it may be fed. It will, in all probability, be late in dying down, but in any case a certain amount of rest is essential. The after-treatment must be as advised above.

CULTIVATION OF CASSIA (*Captain R. H. V.*).—The Cassia referred to is, in all probability, *C. corymbosa*, which requires the protection of a greenhouse. It is a free-growing shrub, whose pinnate leaves are of a deep green colour, and the golden, pea-shaped blossoms are borne in summer and autumn. It forms a handsome bush in the conservatory, is well suited for training to the back wall of a greenhouse, providing it gets plenty of light, and may be sometimes seen during the summer planted out in parks and gardens in the beds of large miscellaneous subjects which are now so generally popular. Its cultural requirements are not at all exacting, as it may be given much the same treatment as a *Fuchsia*, except that, being evergreen, it must not be kept dry in the winter. At that season it needs a minimum temperature of 45° to 50°. Ordinary potting compost, such as a mixture of loam, peat, or leaf-mould and sand, will suit it well. When old it flowers profusely, but seedling plants need to attain a fair size before they bloom freely. It may be placed out of doors during the summer months.

GLOXINIAS AND CYCLAMEN (*O. B.*).—After the *Gloxinias* have done blooming they must be treated as before till the leaves die down and the plants go to rest. Yours will, in all probability, produce a few blooms for some time yet. Then, as they die down in the autumn, keep them quite dry and in a structure where a minimum temperature of 45° to 50° is maintained. Early in the year they may be shaken quite clear of the old soil and repotted in some good compost. Little water will be needed till they start into growth. Like the *Gloxinias*, the *Cyclamen* must be treated as before till the leaves die down, which will probably be towards the end of May or early in June. Then keep them dry for a month or six weeks, after which the corns must be shaken quite clear of the old soil and repotted in a mixture of loam, leaf-mould, silver sand and, if available, a little brick rubble. After they are potted an occasional damping overhead will be beneficial, but do not give too much water at the roots till the young leaves make their appearance. A frame in a partially-shaded position is the best

for them at this season. As the plants grow, plenty of air will be needed, and they are greatly benefited by exposure to light rain and the night dews which often prevail in August. By the middle of September they should have formed good plants ready to be taken into the greenhouse.

FRUIT GARDEN.

RED SPIDER ON VINES (*M. O. K.*).—It is early for red spider to appear on Vines, and if it is not immediately destroyed it will do no end of mischief to your Vines, the foliage being now so soft and tender. To kill red spider with XL All, or with any other fumigator, it is necessary to apply a strong dose, unfortunately too strong for the Vine foliage to stand in its present soft and immature condition. There is nothing else for it, then, but to sponge the affected foliage carefully over with tepid rain-water and Calvert's Soft Soap, using not more than a wineglassful of soap to a gallon of water. It is tedious work, but if you will stick to it, it will soon be done. Keep a sharp look-out afterwards and apply the same remedy the moment another spider is seen, and you will get rid of the spiders in time.

INSECTICIDE FOR APPLE TREES (*C. D.*).—You do not say what pests you aim at destroying, and, of course, that is a very important thing, for indiscriminate spraying is an evil rather than a good. Fungi, sucking insects, such as green flies and scale insects, and caterpillars all need different kinds of treatment. For sucking insects probably Quassia and soft soap will serve best, and it may be made by gently boiling 1 lb. of Quassia chips in water for a couple of hours. Dissolve half a pound of soft soap in warm water and stir in the strained Quassia extract, adding sufficient water to make up ten gallons. For caterpillars and other biting insects arsenate of lead paste is best, and it should be used in the proportions directed on the tins. Nicotine washes are also of great use against green flies and so on, and should be bought ready-made.

SMALL PEAR TREE PROFUSELY BLOOMED (*A. L.*).—A small tree like this so heavily laden with fruit already set is deserving of all the care you can give it. As you say, the tree will cast off some of the surplus fruit itself later on, but it will have no occasion to do so if you in the meantime will gradually ease it of the burden it is unable to bear. Go over the tree carefully as soon as the fruit is set, and in the first place cut out all the badly-formed and small fruit in each bunch, leaving only five fruits, and then in about another fortnight go over the tree again, still cutting out the smallest of the fruits until there are only two left on each branch. Later still, when all danger of any fruit falling is past, you should reduce the number of fruit in a bunch to one, that, of course, being the finest. You will then have a good crop of the fruit. Give the tree a good soaking of weak manure-water from the stable or cow-yard immediately, and mulch the surface of the soil over its roots with a dressing of rotten manure 3 inches deep.

MISCELLANEOUS.

QUASSIA EXTRACT (*North Wales*).—This is obtainable both as a powder and in a liquid form. That which the writer of the article referred to uses is Bentley's Extract of Quassia, a liquid. A 3-inch potful is sufficient for three and a-half to four gallons of water.

TO KILL WORMS IN POTS (*Nit*).—Get about half an ounce of carbon bisulphide, make a hole in the soil of the pot, pour in the carbon bisulphide, and immediately close the hole. This will cause the death of the worms without injury to the plant, so long as the liquid does not come in contact with any large roots.

LARVE FOR INSPECTION (*Hawick*).—The two grubs reached us very dried up, but so far as we can tell they appear to be the larve of the St. Mark's fly, one of them more advanced than the other. These grubs feed for the most part on decaying vegetable matter, but when they are abundant and food scarce they may attack the roots of plants. Carbon bisulphide injected into the soil at the rate of about half an ounce to the square yard, pouring boiling water on the groups of them, or the use of some soil fumigant round any particular plant, will do a good deal towards checking their attacks.

NAMES OF PLANTS.—*No Name*.—1, *Centranthus ruber*; 2, *Pilea muscosa*; 3, *Saxifraga cuneolata*; 4, *Dicentra formosa*; 5, no specimen; 6, *Streptosolen Jamesonii*; 7, *Arenaria montana*.—*W. G.*—1, *Lycaste* species; 2, *Dendrobium* species. Specimens too imperfect to identify correctly.—*Stranger*.—1, *Aucuba japonica* variegata; 2, *A. japonica*; 3, *Elaeagnus pungens*; 4, *Laurus nobilis*; 5, *Ilex Aquifolium* variegatum; 6, *Quercus Ilex*; 7, *Euonymus japonicus*; 8, *Prunus Laurocerasus*; 9, *Viburnum Tinus*; 10, *Euonymus japonicus* variegatus; 11, *Cotoneaster horizontalis*; 12, *Veronica Traversii*; 13, *Sciodopitys verticillata*; 14, *Cytisus* species; 15, *Forsythia suspensa*; 16, *Muehlenbeckia varians*; 17, *Magnolia stellata*; 18, *Prunus serrulata*; 19, *Mesembryanthemum species*; 20, *Hypericum species*; 21, *Jasminum officinale*; 22, *Olearia Haastii*; 23, *Fyrus floribunda*; 24, *Santolina Chamacyparissus*; 25, *Artemisia Abrotanum*; 26, *Alyssum saxatile*; 27, *Epidemium* species; 28, *Arabis albidus*; 29, *Centaurea montana*; 30, *Doronicum plantagineum*; 31, *Galega officinalis*; 32, *Muscaria conicum*; 33, *Polygonum cuspidatum*; 35, *Iris foetidissima* variegata; 34 and 36, specimens too scrappy.—*Crimm*.—The flower sent is that of an *Amaryllis* seedling of no special merit. The cross has not been detected.—*George Dean*.—The Butcher's Broom (*Ruscus aculeatus*).

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

NOTES OF THE WEEK.

Transplanting Red-hot Pokers.—The best time for dividing or transplanting Kniphofias or Red-hot Pokers is this month, when the plants are getting active both at the roots and leaves. Should the weather be dry, a good watering must be given. A good mulching of rotten manure should also be given annually at this time of the year to established plants.

Primroses and Polyanthuses.—We regret that the article on this subject, which appeared on page 195 of our issue for April 19, should have given offence to some of our readers. The sole reason the writer had for referring to the Primrose League was to pay some slight tribute to the keen interest taken by the late Lady Dorothy Nevill in horticulture. In doing so a sentence that has been taken as political inadvertently appeared.

Prunus triloba Alter Flowering.—Now that the blossoms of this beautiful early-flowering shrub are over, the shoots that have recently flowered should be pruned back to within 1 inch or 2 inches of their base, leaving only two or three eyes. As in all cases of pruning, the weaker shoots should be cut back hardest to encourage stronger growth on them. A young tree would not need cutting back to the extent that an older plant would until it had covered its allotted space.

Rapid Growth of Bamboos.—When visiting the gardens at Trebah, Cornwall, a week or two ago, the head-gardener, Mr. Thomas, informed us that last year he measured the rate of growth of a large stem of Bambusa or Phyllostachys Quilboi. In fourteen days this stem attained a height of 11 feet 10 inches, or an average of slightly more than ten inches per day. The plant, which is growing in the open, is a very large one, and some of the stems measure over five inches in circumference.

Delayed Flowering of Amaryllis Belladonna. At a recent meeting of the scientific committee of the Royal Horticultural Society, Mr. Odell referred to the failure of Amaryllis Belladonna to produce flowers in the past autumn, and stated that the aborted flowers were now being developed. Mr. Worsley stated that the same thing had happened in his garden after wet summers, and it was considered by the committee that the conditions obtaining in such a season as the last militated against the proper development of the flowers, though they might begin to form.

Magnolia stellata and Muscari Heavenly Blue.—The combination of these two plants results in a very attractive feature, for the glistening white flowers of the Magnolia are at their best during the time when the rich blue Muscari flowers are expanded. Moreover, there is no objectionable feature in the combination, for the bulbs do not rob the shrubs to any appreciable extent, while the Muscari leaves are not vigorous enough

to interfere with the Magnolia branches. M. stellata should be planted in moderately thin groups in a soil composed principally of loam, but containing a little peat.

A Showy Crab Apple.—Those who do not already possess Pyrus medzvetzkyana would do well to add it to their collections of flowering trees, for it is distinct from any other kind of Pyrus, and the colour of the flowers is different from that of any other flowering tree. In habit very like that of an ordinary Apple tree, it blossoms quite as freely as any of the Crabs, the individual flowers being as large as those of the more showy kinds of P. Malus. The colour is a curious reddish purple, and branches, roots and leaves are all stained with the same shade.

Board of Agriculture and Fruit-Growers.—It is a good sign to find that fruit-growing and other branches of commercial horticulture are at last receiving some attention from the Board of Agriculture. Mr. Walter Runciman, President of the Board, at a gathering of fruit-growers in the Pershore district last week, stated that he advocated the formation of a fruit institute, and promised assistance from the Board, who would put down £3 for every £1 put down by the County Council in bricks and mortar, presumably in the shape of cottages and necessary buildings; and £2 for every £1 provided by the County Council for running expenses.

An Important Fruit Blossom Discovery.—At the National Fruit and Cider Institute, Long Ashton, near Bristol, Professor B. T. P. Barker has, we understand, made a most important discovery relating to the damage of fruit blossom in spring. It appears that a great deal of the damage usually attributed to frost is due to a bacillus, which causes the flowers to blacken and fall off. This bacillus, the name of which is not yet available, has been isolated in the laboratory and is found to increase very rapidly. It will be remembered that Professor Houston, writing in our issue of March 8, page 121, stated that a good deal of the damage to Apple blossom usually attributed to spring frosts was due to the attacks of the Apple-sucker, or Psylla.

A Hint for Raisers of Seedling Daffodils.—At the discussion on the cultivation of Daffodils held on the evening of the opening day of the Midland Daffodil Society's Show last week, the Rev. G. H. Engleheart gave many useful hints to the raisers of seedlings. The most interesting of these was that he believed in transplanting one year old bulbs from the seed-boxes into other boxes 4 inches deep, giving them good soil, instead of allowing them to remain in the seedling-boxes two years, as is usually done. By transplanting he considered he had saved a year of the time usually taken by seedling bulbs to reach flowering size. To get Daffodil seed to germinate freely Mr. Engleheart stated it should be sown as soon as ripe.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Arrangements at the London Daffodil Show.—

With reference to your footnote about Mr. Wright's unfortunate illness on page 205 of last week's issue, I do not see how his being present at the Royal Horticultural Society's Hall would have altered the fact that it was let on the Saturday before the show and that there were no vases available and no tables on which competitors might have arranged their flowers in comfort.—JOSEPH JACOB.

Failure of *Anemone fulgens*.—In reference to the recent correspondence on this subject, seven years ago I planted some in a bed facing south, in a good, rich, light soil. They bloomed well the first year, the second year not so well, and by degrees they almost disappeared. Last year there were several plants blooming in the steep grass bank below the bed, which bank is hard and sun-baked in summer. This year there are more plants in the bank and more blooms, but the latter are rather small. There is still one plant in the original bed with five blooms.—PENWARNE.

Rhododendron Grievei.—This charming little Rhododendron, which has been almost lost to cultivation, was shown in the exhibit of Messrs. Cunningham, Fraser and Co., Comely Bank Nurseries, at the recent Edinburgh Spring Show. It was much noticed by those interested in the dwarf shrubs, and is extremely beautiful with its pinkish white flowers. As shown, the plants were only a few inches high, and were giving good trusses of large and beautiful flowers. The flowers are not the sole attraction of the plant, as Mr. James Grieve, who happened to be at hand when the writer was examining the Rhododendron, informed him that the leaves were fragrant, and an olfactory test showed that the foliage is of a most agreeable fragrance. Mr. Grieve also gave the information that he raised this plant while with the firm of Messrs. Dicksons and Co., the parentage being *dahuricum* × *ciliatum*. It partakes largely of *R. ciliatum* in flower. Mr. Grieve stated that it had been almost lost to cultivation; but it is to be expected that its beauty will cause *R. Grievei* to be largely propagated and cultivated. It is quite hardy and an excellent rock garden shrub.—S. ARNOTT.

Growing Tulips in Grass.—Let me offer my small contribution to Mr. Jacob's problem of Tulips in grass page 189. For a long time I also was daunted by the superstition that they would flower once, indeed, but never again. At last, however, I was rash and planted some Golden Crowns in very poor soil on a steep slope in very coarse grass that afterwards becomes hay. They have now been there some six years. In the course of that time they have so broken up that each original bulb is now represented by eight or ten great broad, grey leaves. But each bulb mass (or nine out of ten) is so strong as to send up yearly at least one bloom, if not two, which amply justifies the purpose of their planting. Emboldened by this, I myself inserted a lot of Gesnerianas into lifeless soil on a Kentish lawn bank four years ago, and these also still bloom, though not very richly, nor have they broken into the masses of my Golden Crowns. At the same time, one blossom in grass is worth ten in a border for decorative effect. The Tulip never looks so superb and so characteristic as in a wild green setting, and I cannot but feel that even such partial profit

as I have pointed out is quite sufficient encouragement for a far wider use of the greater Tulips in grass. Even some ugly Darwins of last year are now again coming up in bloom through coarse herbage.—REGINALD FARRER.

How to Grow *Saxifraga burseriana*.—With reference to the note on the above subject by "Alpinist," on page 191, April 19 issue, it is not for me to champion Mr. Farrer, but I do not think "Alpinist" has treated him quite fairly. "My Rock Garden" was published much earlier than "The Rock Garden," and apparently, when the former was written, the author had not acquired so wide an experience of the plants growing under natural conditions, and it is evident that his observation of plants in their native habitat, in circumstances such as those mentioned in "Among the Hills"

COPRINUS COMATUS, THE FUNGUS THAT SECRETES THE SELF-DESTRUCTING FERMENT USED AS A CURE IN SILVER-LEAF DISEASE. (See page 215.)

(page 267), led him to recommend a different treatment. However, I do not think that "Alpinist" quite realises that, as regards the requirements of a plant in his own particular garden, he must buy his own experience. The most a writer can do for him is to tell him of the plant's requirements in Nature, and then of his (the writer's) own experiences. I will give "Alpinist" my own experience for what it is worth. I have *S. burseriana* and its many forms growing all over my rock garden in sun and shade facing east, south-east and south-west. My rainfall is somewhere about forty-six inches in the year, and the plants have to shift for themselves in dry weather (when they get it). The more sun they get here, the better they flower; but in dry summers, like that of 1911, those in very open exposures suffered badly. I should be interested to learn whether Mr. Clarence Elliott's plants in a south-west exposure in Herts were out on rockwork, dependent on the heavens

for their moisture, or were artificially watered on rockwork or in frames. If one could keep them moist enough in dry spells, I do not think they would suffer here, even in due south exposures; but for the average rock gardener hand-watering on a large scale is not possible, and personally I would not care to risk the *burserianas* in very open exposures in a climate drier than my own. Wherever I grow them they like light, limey soil and plenty of chips on the surface.—MURRAY HORNIBROOK, Knapton, Abbey Leix, Queen's County.

— I bought a small plant of *Saxifraga burseriana* major last year and put it into the hottest and driest corner of my small rock garden. This year it had over sixty flowers on it, nearly all being in flower at the same time. I got *S. b. minor* also, and put that about six inches from the other. In December it was looking so bad that I transplanted it to the shady side of a new rock garden I have just made. It seemed to get better from the moment I transplanted it, and has just finished flowering. It had twelve nice flowers. The petals of these flowers are deeply serrated. Of course, last year was so sunless that that may account for *S. b. major* doing so well in a south-west aspect. Perhaps my experience may be of interest to "Alpinist."—J. C. D.

— A good deal has been written about the above and as to the best aspect to grow it in. Here in Cheshire I have grown it for many years on the south side of my rockwork in full sun, but in the summer of 1911, which was very hot and dry, the plants were much burnt by the sun, and in some instances completely killed. Some other of the *Saxifragas* suffered in the same way. The summer of 1911 was very unusual, and on the whole I consider a southern aspect the best for *Saxifraga burseriana*, at all events in Cheshire. In a very hot, dry county, as in some parts of the South of England, possibly not a fully south aspect would be best.—GEORGE DIXON, Aslie.

— If "Alpinist," who writes in your issue of April 19, will plant *Saxifraga burseriana* in a soil composed of two-thirds lime rubble or lime chips and one-third sandy loam, and place the plants with a southerly or south-westerly exposure, with a rock behind them under which their roots will get the evenness of moisture that they like, he will have no difficulty in growing and blooming this *Saxifrage*. Of course, I assume that the rock garden "Alpinist" has is thoroughly drained to start with. I emphasise the importance of the rock behind, as of two large clumps that I had with the same south-west aspect, the one that did not have a rock behind it showed signs of shrivelling up, whereas the other retains the bluish green foliage, which is a sure sign of health. I have grown this and other *Kabschna Saxifragas* for many years, and my plants of *burseriana* are six or seven years old.—S. H., Hertfordshire.

[We are compelled to hold over other interesting notes on this subject.—ED.]

Erigeron Asa Gray.—This is almost certainly a hybrid *Erigeron*, though it seems difficult to trace its origin or to say with certainty what its precise parents were. One would believe, however, from the colour of the flowers that it has some of the "blood" of *Erigeron aurantiacus* in its cells. It is a very handsome plant, with flowers which some call apricot yellow and others a kind of biscuit colour. It is about a foot high and makes an excellent border plant. It is not the same as the variety of *E. salsuginosus* which is called "salsuginosus of Asa Gray."—S. A.

Azara microphylla at Stranraer.—There is an exceedingly fine plant of *Azara microphylla* in the deeply-interesting garden of Mr. Carrick-Buchanan, Corsewall, Stranraer, a place where many reputedly tender shrubs thrive apace. The *Azara* is generally hardy in South-West Scotland, but the specimen at Corsewall is exceptionally fine on a high wall surrounding the kitchen gardens. Speaking from recollection only of the plant as seen last year, I cannot venture to give the approximate height, but it is one of the finest plants of *Azara* which I have seen, save in Ireland. Its shining green foliage makes a good plant most attractive. It does not appear to fruit well in South-West Scotland, and in a considerable number of gardens it even fails to flower. The non-flowering is of less consequence, seeing that the blooms are small. The agreeable aroma they exhale is, however, welcome in spring. Probably late frosts have much to do with the non-flowering in many local gardens.—S. ARNOLD.

Primula viscosa Hybrids.—There seem now a goodly number of hybrids of *P. viscosa* in existence, and in addition to the two named, Jean Douglas and Othello, referred to on page 187, and a few other named varieties, a considerable number as yet unnamed are in cultivation. It is to be hoped that these may be sent to the Royal Horticultural Society's Gardens to be tested together and the too-much-alike varieties eliminated by a competent authority, such as the floral committee. I have recently seen a considerable number of these new seedlings in flower, and one must say that there is too much similarity among them. Then, again, the use of some of the alpine *Auriculas* as one of the parents has given some of them too great a resemblance to the *Auricula*, and several of the seedlings which it is intended to name are little different from a poor alpine *Auricula*. Yet there are some excellent flowers among these *viscosa* hybrids, and there is no reason why there should not be a number of other good *viscosa* hybrids produced.—AN OLD ALPINIST.

Zonal Pelargonium Maxime Kovalevsky.—This distinct tinted variety of *Zonal Pelargonium*, which is referred to on page 179, issue April 12, is a good kind for pot culture, either for summer or winter blooming. Besides this, it is very effective as a bedding plant, and in this way it formed a very attractive feature in the gardens at Hampton Court last summer. Owing to its distinct shade, a mass of this *Pelargonium* was at a little distance somewhat of a puzzle, the tone of colour being so different from any of the others. It is one of the many good things that we owe to M. Lemoine of Nancy, France, as it was distributed from that establishment in the spring of 1906, and was given an award of merit by the Royal Horticultural Society five years later. It is by no means the only variety that was sent out long before its merits gained recognition, as the universally-grown *Paul Crapeul* was first put into commerce by M. Lemoine in 1892 (one year before *Begonia Gloire de Lorraine*), but it was about a decade after that when it became popular. Much the same applies to that well-known market variety with semi-double flowers, *F. P. Raspail*, which I first received from M. Lemoine in 1878, the year of its distribution. It was long after that before it was taken up by some of the market-growers, when it was at once much sought after. Not only were these three standard varieties all raised by M. Lemoine, but the Ivy-leaved variety *Gallée*, which is perhaps grown more than any other, also came from the same source.—H. P.

PRIZES FOR THE BEST ROCK GARDENS.

To further stimulate the interest that is being taken in rock gardens, the Proprietors of THE GARDEN offer the following prizes for three photographs of a rock garden, or portions of a rock garden:

First prize: Five Guineas, or a Silver Cup of that value.

Second prize: Two Guineas, or Books of that value.

Third prize: One Guinea.

The competition is open only to the actual owner of the rock garden, or to his or her gardener. The object is to encourage good rock gardening, and preference will, therefore, be given to those rock gardens which show originality in design, and where the plants depicted are well grown. It should be distinctly understood that awards will be made to the best rock gardens, and not necessarily to the best photographs. The photographs need not be taken by the competitor, who must, however, in such cases have the written consent of the photographer for their reproduction in THE GARDEN. The competition is subject to the following rules:

1. Not more than three photographs of each garden may be sent in by one competitor.
2. Each photograph must have the full name and address of the competitor plainly written on the back in ink.
3. Successful competitors shall furnish written particulars of the rock garden forming the subject of their photographs.
4. Glazed P.O.P. prints must be sent, and each should be on a mount with not more than half an inch margin.
5. All photographs must be sent to arrive at THE GARDEN Offices, 29, Tavistock Street, Strand, W.C., not later than June 1, 1913.
6. Unsuccessful photographs sent in for competition will be returned if a sufficiently stamped and addressed envelope or wrapper is enclosed for the purpose, but no responsibility will be taken for the loss or damage of photographs submitted, although every care will be taken to return them uninjured.
7. The Proprietors of THE GARDEN reserve to themselves the right to reproduce any photograph sent in for competition.
8. The decision of the Editor will be final.

FORTHCOMING EVENTS.

May 6.—Scottish Horticultural Association's Meeting. Forest Gate Chrysanthemum Society's Meeting.

May 10.—British Gardeners' Association's Meeting at Birmingham.

May 12.—United Horticultural Benefit and Provident Society's Meeting. British Gardeners' Association's Annual General Meeting at Birmingham.

May 14.—Royal Horticultural Society's Meeting and Tulip Show. East Anglian Horticultural Club's Meeting.

May 20.—Royal Horticultural Society's Spring Flower Show at the Royal Hospital Gardens, Chelsea (three days).

May 21.—National Tulip Society's Show at Chelsea (two days). Devon County Show at Barnstaple (three days).

SCIENCE IN RELATION TO HORTICULTURE.

TREATMENT OF DISEASE IN PLANTS.

TWO methods may be employed in the treatment of disease, one preventive and the other curative. So far as general crops are concerned, prevention is the only practical method.

Cures can only be attempted in individual cases, and then only when the disease is local, as, for example, canker in its early stages in fruit trees. In such cases a simple surgical operation will remove the danger.

So far as prevention of disease is concerned, the fundamental rule is to secure a strong, vigorous and healthy growth of the plant—not an overfed, overcrowded and forced growth that weakens the tone of the tissues and renders them a more easy prey to the attacks of fungal parasites. Other factors bearing upon disease are drainage and good tillage, making for healthy root action; the speedy removal and destruction of all infected plants or portions of plants found in the garden, and the use of well-rotted instead of fresh manure.

It is, further, important to select sound seeds from healthy parents, and if possible to choose varieties that possess a relative resistance toward the particular disease that threatens your crop. Then, in such cases as club-root, where the infection comes from the soil, the fungus may be starved out by using the soil for several years for the growth of crops that are immune to the disease.

The most successful method of fighting disease is to prevent infection. In all cases where the trouble is due to fungi the disease starts with infection through spores, and the concern of the grower is to prevent, if possible, the germination of these spores; hence the use of fungicides distributed in the form of a spray.

Coming now to curative treatment, the difficulty of destroying a fungus growing *within* the tissues of a plant is quite obvious. While sprays may destroy all branches of the fungus or fungus spores that appear on or reach the surface of the plant, they are harmless with respect to the internal portions of the parasite.

A method of treatment entirely new to plant pathology, by which the internal parasite is destroyed, has been recently tried by Miss S. M. Baker, with encouraging results. It depends upon the use of a fluid containing a ferment that digests the fungus, while at the same time it is harmless to the host plant. This ferment is obtained from a fungus that must be familiar to all gardeners. It is one of the common Toadstools, distinguished by the fact that when the spores (which are black) ripen, the shaggy cap rapidly melts, forming an milky fluid that gradually drips away. To science it is known as *Coprinus*, a word which is classic for "dung," in reference to its usual place of growth. Dr. Buller has shown that this liquefaction of the cap is really an act of self-digestion, by means of which the fungus liberates its spores—liberates them at a calculated rate of a million a minute! Now, all digestive processes are the work of peculiar chemical bodies known as ferments or enzymes. The change of starch into sugar in a germinating Barley grain, for example, is due to the work of the ferment diastase, just as the peptic ferment

in the stomach digests albuminous food. So in the case of *Coprinus* the fungus secretes an enzyme that, strangely enough, digests its own fruit-body, and thus speedily reduces it to an inky fluid.

This particular fungus, therefore, produces a peculiar ferment that has the special property of digesting fungal tissue, and this fact suggested its application to the treatment of disease induced by internal fungal parasites. Miss Baker, in the current number of the *Annals of Botany*, describes experiments in which she made use of the expressed juice of *Coprinus* in destroying the fungus which is the cause of silver-leaf disease in Plums, &c. Readers of *THE GARDEN* will remember (see page 16, issue January 14, 1911) that silver-leaf disease is due to the presence of wandering threads or hyphae of the fungus *Stereum* (not remotely allied to *Coprinus*), and the idea was to introduce the ferment-containing sap of the ink-fungus into the tissues of the tree infected with the *Stereum*, reasoning that it it was brought into contact with the ramifying threads of the pest, digestion would take place, and so the parasite would be destroyed and the disease cured.

This particular disease is exceptionally favourable to test the efficiency of inoculation, as the effects of the disease become evident in the branches before the hyphae reach the leaves, and produce silverying. If the inoculation of an infected branch prevents silverying, then it may be reasonably concluded that the introduced fluid has a destructive, and therefore curative, power. The method adopted by Miss Baker was first to inject under the rind of the branch a concentrated watery extract of the liquefying sap of *Coprinus*, and, secondly, to apply externally a poultice containing the digesting fluid upon those portions of the dead wood showing the fruit-bodies of the parasite. The experimenter states that "one Victoria Plum tree which had been treated with injections for two years showed no silverying on the leaves of the upper parts of the branch in the autumn of 1912. When treatment was commenced, this branch, the last survivor of the five main branches of the tree, was badly affected throughout; it has now borne fruit in the two successive seasons after a sterility of three years' standing, and has produced remarkably vigorous new growths. The lower parts of the branch near the infected dead wood still showed slight silverying on the leaves last autumn." These results are not only interesting from a biological point of view, but extremely suggestive to all workers in the field of vegetable pathology.

D. HOUSTON.

Royal College of Science for Ireland.

[We should be glad to hear from any of our readers who have had experience with the fungus referred to by Professor Houston. —ED.]

TREES AND SHRUBS.

NOTES ON LILACS.

OF all spring-flowering trees and shrubs none is more appreciated than the Lilac. Even the ordinary form of *Syringa vulgaris* is lovely, but when we consider the intensity and variety in colour, the huge panicles of blossom of both double and single varieties, one cannot wonder at the appreciation the newer forms find with those who are conversant with them.

A few comparisons will show the advance that has been made during the last fifteen years or so. The variety Charles X. is a form of *S. vulgaris* in which the panicles are thicker and the blooms

Few persons will say that in an ordinary garden Lilacs receive the attention they deserve. Often they are cramped in between evergreen shrubs, where they are forced to grow tall and ungainly, or they are planted under forest trees which eventually overhang them. In such a position they cannot get the necessary amount of light they require to mature their annual growth. The roots, too, are unable to obtain the moisture they require or the plant food necessary. Abundance of space in full sunshine is necessary to do them justice, in order that the growths may become properly ripened each season. Without maturity of growth they cannot flower properly. Freedom of growth should be encouraged; the stronger the shoots the finer the blossoms. Weakly shoots can only produce similar inflorescences.

The choicer varieties are usually grafted, and too often the suckers which spring from the various stocks are allowed to rob the plants of much of their energy. All such suckers should be removed directly they are detected. Lilacs will grow in almost any soil, but that of a heavy rather than a light nature is best, as in such soil the flowers develop a richer colour tint. The panicles, too, are stouter, consequent on such soil retaining moisture longer, as it too frequently happens that a dry spell is often experienced during the early part of May, when the panicles are developing.

Deep trenching should be practised before planting, and an abundance of half-decayed farmyard manure may be added at the same time. Established plants should be given a liberal top-dressing of bone-meal, superphosphate, or towl-manure early in April, lightly forking it in for the benefit of the surface roots. This should be followed with a mulch of half-decayed stable manure as the panicles lengthen. Copious supplies of liquid manure are distinctly beneficial.

If extra large panicles are required, they should be thinned and the bulk of the shoots growing around the panicles pinched at the first joint, which will concentrate the whole energy of the branch to the selected panicle. As to pruning, some discretion is needed. When first planted, the

previous year's shoots should be pruned to within an eye or so of the base, with a view to getting a dwarf specimen of good shape, and also to induce future vigour of growth. In the future the cutting of the panicles of bloom will be nearly all the pruning the bushes require. Weakly shoots should be removed, allowing more space for the stronger growths.

Single-Flowered Varieties.—*Alba magna* is quite the best of the section, being pure white, free and especially fragrant. *Marie Le-graye* is creamy white. *Alba grandiflora* is freely furnished with smaller flowers than the preceding. *Negro* is attractive with its intense purple blue shade. *Othello* is desirable; the blooms are so placed on the panicles that they do not overlap each other.

THE DOUBLE WHITE LILAC MME. LEMOINE.

richer in the shade of purple. This was at one time considered to be a great advance, and was held in high esteem. Charles X. is now surpassed by *Souvenir de Louis Spath*, in which the colour is again intensified, the panicles larger. For garden decoration it is difficult to imagine a more beautiful Lilac. A shapely bush of this variety will in ten years produce 300 large panicles; these densely coloured blossoms are most effective. The flowers last a long time in a good condition. Take, again, the double-flowered variety, *Mme. Lemoine*, with its pure white, huge flowers, thickly set on panicles almost a foot in length, many panicles having three spikes each; and when we consider how well this Lilac fares in pots, the wonder is that more plants are not grown

The deep claret-coloured flowers have a red border. The deep violet purple of Uncle Tom is distinct. Dr. Mirabel has tall, erect panicles of claret-coloured buds, opening into purple lilac flowers. Gloire de Lorraine has red buds changing to violet. Professor Stockhart is a lilac shade of blue. Gloire de la Rochelle is also of a similar tint of colour after the rosy lilac flowers have become a trifle aged. The wine red colour of Pasteur is attractive. Duchesse d'Orleans is quite a new light blue. Mme. Kreuter is furnished with large spikes of various red flowers. Toussaint Louverture has dark crimson flowers which change to dark violet. Aline Marqueris is reddish purple; Philemon, dark red; Mme. Briot, bright red; Mme. F. Morel, with large blossoms on stout panicles, is of a showy purple colour. Hyacinthiflora is a very pretty variety with pale blue flowers, produced in long, rather thin panicles. Congo is very large in flower and red in colour.

Double - Flowered Varieties. —

There are no fewer than ten white-flowered sorts, all of which are worthy of a place in a large collection. Much the best is Miss Ellen Willmott. The pure white flowers are large and the panicles fine. Mme. Lemoine produces longer panicles, but the flowers lack the size and purity of colour of Miss Ellen Willmott. Mme. de Miller is a dwarf-growing variety. Jeanne d'Arc, Taghoni and Banquise are new. Mme. Casmir-Perier has thick panicles of rather dull white flowers. Mme. Abel Chatenay is a magnificent flower and is later in developing than any other white variety, and for this reason should be included, as it prolongs the season considerably.

Coloured varieties are numerous. Condercet produces the largest panicles of any. The flowers are an attractive shade of blue. President Grévy, with the cobalt blue, rose-edged flowers, is attractive. Maurice de Vilnorm is especially thick in the panicle; the rich red colour of the buds is attractive, and when expanded they are blue with a white centre. Dr. Troyanowsky has enormous panicles of rosy pink buds which, when open, are azure blue. Comte de Kerchove I like much—it is so free in flowering; in colour the buds are a rich red, and the open flowers are rosy pink.

President Loubet is a fine variety, with carmine buds and deep purple-red flowers. Comtesse Horace de Choiseul has creamy white flowers shaded with rose. Michael Buchner has pale lilac-coloured flowers with a pink margin to each. La Tour d'Auvergne is very double, violet purple.

E. M.

A DISTINCT BARBERRY.

(*BERBERIS CONGESTIFLORA HARZOIDES.*)

THERE are such a number of Berberises now, the majority of which flower in the early spring, that they are apt to become bewildering; but the subject of this note is one that is so conspicuous, both in growth and habit, that it would be difficult to mistake it for any of the others. It is an evergreen of upright growth, with greyish green leaves almost circular in shape, spiny on the margins. The flowers are orange yellow in colour, and are borne in clusters on short, upright stalks.

E. B.

THE ROSE GARDEN.

SEASONABLE WORK AMONG THE ROSES.

ROSE growth should be making rapid progress by the middle and end of May, and in not a few instances there will be flowers upon our early varieties in warm quarters.

It is this early growth that often gets much affected with green fly, which only wait until a suitable change in the weather to spread to all parts of the Rose garden. Whether it be fighting mildew or aphides, we shall do well to attack them as early as possible. A splendid mixture against all foes is made by using Jeyes' Cyllin Soft Soap, at the rate of not quite 1oz. to a gallon of water. Dissolve the soap in boiling water. A couple of pounds may be dissolved in a quart

to fill the centres of the plants, they should be cut or punched away before absorbing much nourishment from the plant, and there will generally be a good deal of this to do during May. The hoe should also be in evidence now, not only as a preventive against weeds, but for stirring the surface of the soil, to which most growers attach great importance. There will be the removal of suckers and staking of maiden Roses to attend to, and it a little of the well-cultivated soil is drawn round the base of dwarfs, much support, as well as a better union of Rose and stock, is secured. Consider the average growth of the variety when staking for support. The height and strength of the supports should vary in accordance with the growth, and a much better appearance is obtained when three assorted sizes are used with a little judgment.

Plants that have given their main crop of blooms under glass need care and attention if they are to be of future service. To stand these on one

DAFFODILS NATURALISED AT CLANDON PARK. (See page 218.)

vessel, and if it can be kept simmering for about twenty minutes it seems better. Of course, one will be careful to mix the solution to a proper strength before syringing, bearing in mind that the ratio should not exceed 1oz. to the gallon; a little weaker strength can be used more freely and will be more useful. It can be applied cold, but is rather more effective when used at a temperature of 70° to 80° Fahr. One can scarcely be too prompt and persistent in the use of washes, nor should there be any delay in capturing grubs, caterpillars and leaf-rollers, which are certain to be about as soon as warmer weather sets in. Washes check these foes; but no method is so effectual and simple as hand-picking or squeezing between the finger and thumb.

However well one's Roses may have been pruned, a little looking over and removal of ill-placed growths will be beneficial. Where these are in any way overcrowded, or with an undue tendency

side will not do; rather, give every care to the securing of some good wood as a groundwork for next season's winter forcing. This is all the more essential with the climbing and weeping sections, for the whole of next year's crop of blooms depends in a great measure upon good and well-matured rods. Too often these plants are placed in the open full early, and so receive an injurious check, to the great detriment of the future crop.

In the case of worn-out plants, it will generally be found advantageous to plant these in the open ground, and grow on younger stuff to replace them. Once a pot plant has greatly deteriorated, it is far more difficult to bring it to a satisfactory condition; but when most of the soil is removed and the plant given fresh soil outside, a good autumn display and healthy growth for further use for the following year are obtained. It is a cheese-paring policy not to have the very best wood where the extra expense of heat and attention is given.

A. P.

THE FLOWER GARDEN.

SOME GOOD PENTSTEMONS FOR BEDS AND BORDERS.

DURING recent years considerable attention has been given to the smaller-flowered forms of Pentstemon, of which the best known in gardens is the Newbury Gem class. Their greatest recommendation is found in the profusion with which they flower, but their extended season and rich, bright-coloured flowers are potent factors that speedily win them recognition in all departments of outdoor gardening where a bright and prolonged display is desired. They are delightful subjects in almost any position in the garden, but their great beauty is most fully disclosed when planted lavishly and preferably grouped in quantities of each variety, for once they come into flower there is never a dearth of blossom, and the display continues right up to the period when autumn frosts prevail. The set includes Newbury Gem, with carmine red flowers and spotted throat, the white form and a pale pink form. There is also a hybrid form named Southgate Gem, in which the flowers partake more of the character of a florist's variety, the tube being crimson and the throat white. In the hybrid form named Myddelton Gem the flowers are coloured rose carmine, shading to rose white, the tube being white, edged with the same colour. This section of Pentstemon is subshrubby. On light, well-drained soils the plants frequently survive the winter, and in consequence come into flower earlier in the season than is the case with plants obtained by propagating from cuttings in autumn and wintered in frames. The latter, under normal conditions, come into flower towards the end of June. A species of small-flowered Pentstemon not generally given the recognition in gardens that it deserves is *heterophyllus*. In its flowers it presents a phenomenon one occasionally notes among blue-flowered plants, in that it requires brilliant sunshine to develop the colour pure. Given favourable conditions then the plant is effective, and one of the most desirable in the entire genus. It is a subject I have found quite hardy on a limestone soil when given a position where surface water and moisture readily percolate away. It may, however, be easily propagated from seed, which comes true and flowers in the season following that in which it was sown, or it may be propagated by cuttings in early autumn in the usual way. *P. Kellermanii* is another species with small flowers, the colour being an uncommon shade of dark reddish purple or mahogany colour. Like Newbury Gem, it flowers profusely from autumn-struck cuttings or older plants. On well-drained soils it is perennial, forming a leafy, rounded bush some twenty-four inches to thirty inches in height when in flower.

Combe Court Gardens.

THOMAS SMITH

GARDENS OF TO-DAY.

SPRING FLOWERS AT CLANDON PARK.

CLANDON PARK, the country home of the Earl of Onslow, is situated amid the charming scenery of the Surrey Hills and at no great distance from Newland's Corner, a prominence that commands one of the finest views in the South of England. A footpath, well known to those who appreciate rambles in this delightful county, runs through the park, joining up the old-world villages of Clandon and Merrow.

A VIEW IN THE PRIMULA DELL AT CLANDON PARK, SURREY.

In Daffodil-Time.—It is a pleasant walk at any season of the year, but more especially so in Daffodil-time, for on entering at the Clandon Gate a magnificent sight is revealed. A wide expanse of well-timbered parkland is aglow with Daffodils. Over four hundred thousand bulbs have been planted, among them being Emperor, Sir Watkin, Barri conspicuus, Horsfieldii, Poet's Narcissi and most of the older varieties. Oriental Poppies and English and Spanish Irises are all naturalised over the same area, and form a succession of bloom long after the Daffodils are over.

The Primula Dell.—Following our path from the Clandon side, we at length reach a rustic bridge, from which rainbow trout may be seen disporting in the pool below. A little stream from this pool flows through a copse that dips down by the side of our footpath, and it is this little glade that has been converted into what is aptly called the Primula Dell. The beautiful undulating woodland of this Surrey garden, with winding paths and a deep, retentive soil, provides just the ideal surroundings for a natural Primula garden. Mr. Blake, the able, all-round gardener—with a special fondness for Primulas—has displayed exceptionally good taste in the grouping of these hardy flowers in a natural way. In preparing the dell for Primulas, a deal of undergrowth had of necessity to be cleared away, and the soil, naturally of a heavy nature, had been dug over and left in a rough condition. The spaces between the large clods of clay were filled in with leaf-mould, and it is in these niches that Primulas have been planted, with such admirable results. *Primula rosea*, the daintiest of all Primulas, has been treated in this way, and is now colonised in large masses by the stream-side. This year the brilliant show of bloom has surpassed that of all previous seasons. *P. denticulata* and its improved and immensely popular form *cashmeriana* are the first to flower, and these are shown in the illustration on page 219 in association with the Leopard's Bane, the result of accidental planting, but, nevertheless, creating a brilliant scene of woodland flowers. Wind-flowers are not excluded from this lovely garden, and *Anemone apennina* is the subject in the foreground of the illustration on this page, while the slope behind is clothed with *Primula denticulata*.

P. japonica, now sending up its sturdy flowering shoots, is so much at home that self-sown seedlings spring up each year in scattered places. Polyanthus in a variety of hues, but mainly those with primrose-coloured flowers, are flowering profusely in shady slopes under Ivy-clad trees and on the banks of a little stream. It is interesting to note that the hybrid *Primula kewensis* has been tried outdoors. A year or so ago self-sown seedlings were taken from under the greenhouse staging and planted in the dell. They grew for a time, but ultimately succumbed, and further attempts have not been made to grow this interesting plant outside. The Polyanthus are followed by *Primulas frondosa*, *pulverulenta*, *Venticii*, *japonica*, *sikkimensis*, *bulleyana* and *capitata*, all of which flourish amazingly in this dell and prove beyond doubt that for beautifying a damp, rather low-lying piece of open woodland there is nothing to equal the hardy Primulas.

THE GREENHOUSE.

SOME GOOD FLOWERING CACTI.

THE most striking among these just now are the two distinct *Epiphyllums*, which are so widely removed from the old *E. truncatum* and its several varieties. In the first place, their period of blooming, their self scarlet colour and, above all, the regular shape of the blossoms compared with the oblique ones of *E. truncatum* are marked points of difference from the older kind. The two spring-flowering forms referred to—*E. Gertnerii* and *E. makoyanum*—closely resemble each other, so much so, indeed, that though the difference between the two may be readily detected when they are compared side by side, yet the general effect is the same. The style of growth is reminiscent of *E. truncatum*, and like that well-known kind, these scarlet forms will thrive best when grafted on to the *Pereskia*. The different *Phyllocacti* have also unfolded their earliest blossoms, and the gorgeous colours of some of them make one wonder that they are not more often grown, particularly as their cultural requirements are so simple. That they are of little or no value for cut purposes is, perhaps, the reason that they are at the present day to a certain extent under a cloud. Complaints of their non-flowering may often be traced to unsuitable treatment. During the summer the plants should be fully exposed to sun, so as to ripen the wood and ensure the formation of flower-buds. They should at that season also be well supplied with water—a necessary precaution—as there is a tendency, owing to their succulent nature, to keep them too dry during the growing period. In winter very little water will be needed.

The vivid and quite indescribable tints of some of these Cacti constitute their greatest charm. To many those that appeal the most are the varieties in which the interior of the flower is shot with violet, blue, or purple. When this is in combination with a bloom principally of an orange or salmon shade, the effect is almost unnatural. Some of the rose-coloured forms are very attractive, as is also the creamy white *Cooperi*. The small-flowered *Phyllocactus phyllanthoides* *German Empress* is remarkable for the profusion in which its rose-coloured blossoms are borne. Its merits are so great that it should on no account be passed over in any selection of *Phyllocacti*, although it does not arrest attention by reason of the startling nature of its blossoms as many of them do. All the *Phyllocacti* strike readily from cuttings if they are not kept too moist. If the plants need repotting, the time to do this is directly the flowers are over. A mixture of two-thirds loam, and the remaining third made up of leaf-mould, broken brick rubble and sand, will suit them well. When repotted the plants should be securely staked, otherwise from their weight they are apt to sway about.

H. P.

DAFFODIL NOTES.

THE LONDON DAFFODIL SHOW, 1913.

IN both quantity and quality the Daffodils shown this year excel those of 1912. Then the season was very exceptionally early, whereas this year flowers were, in many parts of the North and the Midlands, no earlier than usual; at any rate, at the time this show was held. The large trade exhibits were excellent, and, taken all together, they provided an immense number of varieties from which the visiting public might pick and choose. Messrs. James Carter and Co. of Raynes Park and Messrs. Sutton and Sons of Reading departed, as they have done before, from the usual plan of staging a mixed collection of single vases of different kinds. They grouped bold masses of one sort, and so gave people an idea of what the flowers would look like

It is a small *Barri* with an all-red eye or centre, and with a fairly well-shaped perianth of a very decided pink shade. As this is the second year that it has flowered at Black Torrington, Devonshire, we may take it to be constant. Mr. A. M. Wilson had a single bloom of much the same tone, but not so deep a shade. He tells me that others are coming along, and that we may expect developments in this direction. Opinions were much divided about its beauty among the experts. I decidedly liked it. The two colours harmonised so well. The pink shade of the segments, which gave me the idea that it had "body colour" mixed with it—to use a painter's simile—was just the thing to go with the dull red cup; but Mr. Frank Galsworthy, the well-known flower painter, "did not like it at all" and was "horrified" to see it.

Mr. Engleheart singled out an exceptionally lovely flat-eyed Leedsii, *St. Old*, size $3\frac{1}{2}$ inches by $1\frac{1}{4}$ inches (illustrated on page 204 last week),

AN EFFECTIVE GROUPING OF HARDY PRIMULAS AND LEOPARD'S BANE.

in a garden bed. I must own that this idea is a new one to me, and that it was suggested by a lady who is very fond of her garden and is always on the look-out for "effects." It struck me as eminently reasonable and an idea that might be more often carried out than it is. Carter's group was especially good in this respect, as the blooms were more nearly on the ground-level. I must, however, leave details of these, for there is so much to say about the best and newest individual varieties that were to be seen in the Royal Horticultural Society's Hall on April 15 and 16.

I think it will be an agreeable change for readers to have the views of various people as to what they considered either the best or the most novel blooms. In some cases my own opinion coincides with theirs, in others it does not; while there are a certain few that nobody that I asked seem to have noticed.

The greatest departure from the ordinary was to be seen in *Red Wing*, which the Rev. T. Buncombe staged in one of the competitive classes,

which most deservedly gained an award of merit. Among all the countless varieties which he had raised, he said, it was one of those which gave him the greatest pleasure. Three grand vases of this stood out very prominently in the centre of Messrs. Barr's stand. The large, flat, deep cream-coloured eye is distinct among Leedsii and gave the flower its great charm.

Mr. R. Morton, who won a great many prizes in Section III. (for amateurs only), cast his vote in favour of Messrs. E. H. Krelage and Son's marvellous exhibit of trumpets in Class 2. Included among them were *Mrs. Ernst Krelage*, the famous white of exquisite texture and faultless shape, which secured the much-prized distinction of a first-class certificate; *Hope of Holland*, soft yellow, with a bold, smooth edge to the trumpet, size $4\frac{1}{2}$ inches by $1\frac{1}{4}$ inches by $2\frac{1}{8}$ inches, practically a self; *Seedling No. 112*, a very deep yellow, with a flat, star-shaped, overlapping perianth and a well-proportioned trumpet; *Glory of Haarlem*,

a fine big yellow; and South Pole, a good pale bicolor. It certainly was a fine exhibit.

Mr. C. Bourne considered the forty-eight of Mr. E. M. Crosfield, which secured first prize and the gold medal in Class 1, as the best collection ever seen in London, and few will disagree with his judgment. Of individual varieties he singled out Maid Marion (P. D. Williams), which is the acme of grace and refinement among the bicolor Ajaxes. It is by no means large ($3\frac{3}{8}$ inches by $1\frac{3}{8}$ inches by $1\frac{3}{8}$ inches), but its proportions, shape, texture and soft colouring are all that one could desire. My comment is, "quite a Bourne flower." How the old father would have loved it!

Captain Kitchin, the child of Brecon, where first of all his Daffodil love was aroused, liked King Emperor, a fine flower, even among Mr. Welchman's superb yellow trumpets. Its texture was, as it were, of the finest silk, and its soft colouring most pleasing. Size, 4 inches by $1\frac{5}{8}$ inches by $1\frac{3}{8}$ inches. Mr. P. D. Williams said the bloom that he would like to live with was his own beautiful pale seedling Susan. It is very *chic*, very sweet, and so very unassuming that none but those with the "loving eye," as Mr. Edward Thring of Uppingham used to call it, would ever have noticed it. Susan has a small, flat eye of the palest lemon shading to green, and long, narrow, pure white segments. Size, $3\frac{1}{4}$ inches by five-eighths of an inch. Mr. "Alpine" Farrer saw it when I took him round some of the "choiceties" of the show, and was greatly impressed with it. He remembered my description of it a year ago, and had often wanted to see it. He was *not* disappointed—no mean praise when one's expectations are satisfied.

Both Mr. W. A. Milner and Mr. Herbert Chapman thought Mr. A. M. Wilson's Harpagon one of the most striking of all the new varieties. It is what of old would have been classed as an Engleheartii, with an all deep red eye and a pale primrose perianth whose segments slightly incurve. Size, $4\frac{1}{2}$ inches by $1\frac{1}{4}$ inches. It was certainly striking. What put this idea of a mild symposium of people whom I casually met into my mind was Mr. Chapman taking me to see the Daffodil in the hall.

The Rev. T. Buncombe had very great difficulty in saying which he thought most worthy of special mention. Ultimately he settled upon Ihex, Hereward and Miami as his favourites. Ihex (E. M. Crosfield) is very similar to Lysander (P. D. Williams), and both may be roughly described as looser and more star-shaped forms of the celebrated Challenger. They were exhibited in the singles, and as I happened to be one of those who judged them, I was very satisfied to know that our decision was in accordance with that of the two owners, who have had much friendly discussion about

their relative merits. Lysander gained the first prize. It was just a shade the better florist's flower. Size, $3\frac{3}{8}$ inches by seven-eighths of an inch. The cup is of deep orange, edged red, and the perianth pure white, with three flat segments and three inclined to recurve. Hereward is a deep yellow Ajax of the highest class. It has a more refined trumpet and a quite flat perianth which is very slightly hooded towards the outside of the perianth. Broad-backed might suggest its form. Size, 4 inches by $1\frac{3}{8}$ inches by $1\frac{3}{8}$ inches. Miami is a cool-looking bloom of much substance and great smoothness, very pale primrose in

also liked Sybil Foster, Mr. Mallender's large white trumpet, which has an ideal perianth and is a flower which, if only it had not such a long trumpet, would be one of the highest-priced ones of the world. As novelties, "Uncle Robert" decided upon Anicet and Antony. The former is a pure white Leedsii with a narrow rim of real pink to the cup; very dainty, delicate and innocent-looking. The latter (Antony) is one of the most distinct giant incomparabilises; bar the pink-petalled Red Wing, one of the greatest novelties in the show. The cup is quite away from anything else in the way it rounds in towards the bottom.

Maggie's Cup is a little like it in shape. Size of bloom, $4\frac{1}{4}$ inches by three-quarters of an inch by $1\frac{1}{2}$ inches. Perianth lemon and very smooth. Cup deep yellow, with a slight flush of red.

There is no need to ask Mr. Walter Ware about his particular favourites. As a rule, you have only to go to his stand (which is invariably a *multum in parvo*) and see the new things he has just acquired. Here was a giant Leedsii—in his own expressive language, a "topper"—long in stem, of good form and superior quality. He considers it the equal of Empire in its own line, and hence has called it Kingdom. The short trumpet is a lovely shade of greenish sulphur, and there is plenty of green in its back.

Mr. Bennett-Poë took me to Messrs. Bath and Co.'s Flame when I asked him what he thought stood out as something uncommon. It is a huge super-Barri after the style of Brillancy, which in turn is a sort of glorified Barri conspicuous. He calls it in a letter to me "a flower of wild form, of great size and striking colour." "Wild form" is good. "She looks very wild" we say of a lady with dishevelled hair; so is Flame. The petals are dishevelled.

My "likes" not previously mentioned were Aladdin (bicolor trumpet), Raeburn (Poet), King Solomon (pale sulphur Ajax), Bayardo (after Buttercup) and Anthea (a very refined Leedsii). I have others too numerous to mention. I hope they will pardon my not including them. Even THE GARDEN cannot hold accounts of every lovely "Daff," good and kind as it always is to them.

JOSEPH JACOB.

NARCISSUS EMERALD EYE.

This beautiful new Daffodil, which was shown by Messrs. Cartwright and Goodwin at the Midland Daffodil Show last week, and a report of which appears on another page, was considered by experts to be the new variety in the show. As its name suggests, the eye of the flat cup is a beautiful and distinct shade of green, and the lower flower of the two was of perfect contour. Unfortunately the illustration does not convey a proper idea of the quiet charm and subtle beauty of this new Narcissus.

NARCISSUS EMERALD EYE, A BEAUTIFUL NEW VARIETY SHOWN AT THE MIDLAND DAFFODIL SHOW.

colour. The lemon eye is almost quite flat. Size, $3\frac{1}{4}$ inches by seven-eighths of an inch.

Mr. T. Batson said Loki (E. M. Crosfield) gave him great pleasure. It is a sort of flat Frank Miles, pale yellow in colour. Size, 4 inches by three-eighths of an inch by seven-eighths of an inch. It has a similar look about it to Miami, but with a cup and not an eye, and it is of a deeper colour.

Mr. Robert Sydenham singled out King Cyrus. It is one of the large, flat, all-red eyes. The size of the bloom and the deeper shade of colour round the outside of the eye make it a striking flower. Size, $3\frac{3}{8}$ inches by three-quarters of an inch. He

GARDENING FOR BEGINNERS.

THE POLYANTHUSES: HOW TO RAISE AND GROW THEM WITH SUCCESS.

AMID the wealth and beauty of spring-flowering plants, none surpasses and few equal that of the Polyanthuses, or Bunch Primroses. They are, indeed, everybody's flower; perfectly hardy, free flowering, beautiful and varied in colour, and of easy cultivation withal. Moreover—and this, indeed, may be one of the chief secrets of a popularity which is universal—they may be raised in their thousands from seeds at quite a small outlay, hence are available for creating effects in April and May of which no other plant is capable. Then, by way of adding to their value from the utilitarian standpoint, it may be stated that in large degree they reproduce themselves fairly true from seeds, hence may be planted in bold masses of colours if so desired. Purity or trueness to colour, however, is often a question of seed selection and isolation of the colour groups. But whether true to kind or in mixture, the strain, assuming it to be one of repute, will of a surety give satisfaction, whether by the size of the individual flowers, the giant character of the trusses, or the profusion of blossoming. In short, so much attention is being paid by the seed-growing specialists to these plants to-day that there is no reason for the presence of strains of inferior quality in our gardens; much less should those of weedy appearance be tolerated. A well-cultivated clump of a year old plant, grown under favourable conditions of soil, may approach to a foot high and as much through, and be crowded with flower-trusses. Such, indeed, may result where the loam inclines to clay, and where it is of good depth and natural richness. In lighter soils the plants are invariably less vigorous, though special cultivation may, even in these circumstances, mean much to them.

How to Raise the Plants.—It should be stated at once that there is no method to equal that of raising seedlings periodically, though in certain soils the divided plants give uncommonly good results. The seedling plant, however, possesses a freedom and vigour of its own, and for all ordinary purposes and for the amateur who gardens with hundreds as much as the professional gardener who may require them in their thousands, seedling-raising will be found much the better way—better by reason of results, which are usually of a reliable nature, and because of a more uniform development and generous flowering.

Sowing the Seeds.—Seeds may be sown from January to August, though a more usual period is from May to August. Early sowing in such a case is, however, conducive to large plants, and where the latter are required to give effect in bold masses, a start should be made in good time. These earliest sowings should be made in boxes or pans in a cool greenhouse, while the August sowings would be best made in a secluded spot in the open, or with frame protection. In the case of rather

heavy, loamy soils that are both cool and moist, it has been found a good plan to sow the seeds on the surface of a well-prepared bed of soil, giving little or no soil covering to the seeds. In soils of lighter texture, a shaded position should be selected, or shade provided by branches of evergreens or in other ways. If quite thinly sown, the seedlings may remain till early spring before transplanting them. When sowing the seeds in boxes or pans, thin sowing is equally desirable, as is also shading from direct sunlight till the seedlings are well in the rough leaf.

Transplanting the Seedlings.—The February to May sown batches will require to be pushed along rather briskly, and to avoid overcrowding

tending to great leaf-production. In lighter soils a free use of cow-manure might be indulged in. September and October are the best months to transfer them to their permanent quarters. E. J.

REPOTTING ASPIDISTRAS AND HOUSE PALMS.

THERE is no better time for doing this important work than the latter part of April and the early days of May. Just then the new leaves of Aspidistras are pushing up from the base and the growth of most Palms is getting active, so that the new roots which are formed quickly grip the new soil and the plant receives the minimum check. Too often, however, amateurs repot these

A BED OF SEEDLING POLYANTHUSES EDGED WITH AUBRIETIA.

or checking their due development, the seedlings should be transplanted as soon as large enough to handle. The position selected should be one of comparative shade and shelter, with uniform coolness, the last the most desirable of all. These Bunch Primroses, like the common or single kind, revel in cool places, while only existing by comparison in positions more exposed, hence the need for providing shade where it does not exist naturally. The seedlings should be transplanted 4 inches to 6 inches apart from plant to plant, and about nine inches from row to row to admit of weeding, hoeing and the like. An important item through all the stages of the plant is a plentiful supply of moisture, dryness at the root or overhead being detestable to the plants. Apart from the ordinary waterings overhead, soot-water will be found of much assistance in dry seasons in keeping red spider and other insect pests at bay.

General Cultivation and Final Planting.—Polyanthuses prefer a good, well-bodied moist loam of moderate richness, excessive manuring in such

plants when such a course is not necessary. Often a top-dressing of good new potting soil would suffice and, indeed, be more beneficial. Aspidistras especially do not object to their roots being confined to a small area, providing suitable food in the form of liquid manure or the top-dressing already referred to is provided.

A suitable soil mixture for Aspidistras and most of the Palms grown in rooms is composed of sweet, partially-decayed loam two parts, thoroughly-decayed manure and coarse sand half a part each, with a good handful of bone-meal and a similar quantity of soot to each half a bushel of the mixture. The plant to be repotted should be turned out of the old pot, and the drainage and as much of the old loose soil as conveniently possible removed, taking care not to unduly injure the roots in doing so. Place it in the new and correctly-drained pot; then carefully ram the new soil all round it with a blunt potting-stick, so that when finished the plant will be about half an inch lower in the soil than it was before. V. V.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Pleasure Grounds.

Care of Paths.—After rainstorms all catch-pits should be gone over and thoroughly cleared of sand, or it will soon lead to a general stoppage of the drainage system.

Rolling.—Paths should be well rolled after rain, so as to keep a good, hard surface. If this is not regularly attended to, they soon begin to crumble up after a few days' drought, particularly when there is much traffic on them.

Weed-Killer.—This should be applied, if possible, when the paths are in a moist condition after rain, though rain immediately after applying it often nullifies its effects. Such an operation should not be left to an irresponsible person, as considerable care is necessary in applying it near the grass verges, or these will be damaged. Needless to say, all cans, water tanks, &c., must be thoroughly cleansed after using, and the surplus weed-killer kept under lock and key.

The Flower Garden.

Baskets and Tubs.—Where these are utilised for the embellishment of the garden, it is a good plan to get them filled as soon as possible, so that the plants in them are nicely established when the time comes to put them out. If a large cool house is at liberty where the receptacles may be filled and the plants in them grown for a week or two, so much the better; but, failing this, a temporary structure of canvas will do quite well, the shelter thus provided being just sufficient to allow the plants to get nicely established without any check and subsequent loss of foliage.

Calceolarias.—It is a decided advantage to plant these early, and if the show of bulbs is over in the beds in which it is proposed to plant Calceolarias, they should be cleared at once, working in nice short manure and planting as soon as possible. Naturally, one would not choose an exposed position for this early planting, unless provision can be made for covering the beds in the event of late frosts.

Plants Under Glass.

Cannas treated as advised in the calendar for March 8 should now be sufficiently well rooted in 4-inch pots to warrant their being potted into their flowering pots (6-inch). A good, rich compost is necessary to ensure good bloom, as also is very firm potting to keep the foliage and growth generally dwarf. A great amount of heat is not necessary at this stage, but a fair amount of atmospheric moisture is necessary to keep them in really good condition and free from spider.

Chrysanthemums.—No matter at what stage the Chrysanthemum plants are, providing they are nicely rooted they will be the better for removing to the open air, though it is wise to select a sheltered position for them so that they are not damaged by wind or late frost.

Stopping.—Some few varieties, such as the Jameson Lumley, Mrs. Henshaw, Fred Green, Fred Chandler, Miss Rodwell and H. D. Thomson, will have to be stopped during the early part of this month if bloom is required for early November.

The Kitchen Garden.

Planting Out Onions.—Plants raised in pots, boxes, or frames should be planted out at once, having previously made the soil as fine as possible. Firm planting is essential, and if the weather continues dry after planting, it may be necessary to give them a watering in, as well as a spraying overhead each evening till growth recommences.

Leeks.—These also should be planted out in trenches prepared in much the same way as for celery, allowing from a foot to 18 inches between the plants. On light soil the trenches may be fairly deep, but on heavy soil this is not an advantage, as a quicker growth is maintained when the Leeks are planted nearer the surface of the soil.

Runner Beans.—One or two rows of these may be sown at any time now, selecting a piece of well-manured and deeply-dug ground. Prizewinner and Scarlet Emperor I have found to be exceptionally good-topping varieties.

Lettuce, Carrots and French Beans in frames must be given plenty of air during the hottest part of the day, and to come a quick growth a

fair quantity of water must be given, and a dressing of artificial or manure-water should be given as required.

Fruits Under Glass.

Figs in cold houses are now swelling their fruit, and every advantage must be taken of the sun-heat, shutting up the house or houses early in the afternoon after a good syringing; this, of course, only on fine days.

Late Strawberries in frames must be well looked after, giving them all the air possible during fine weather. It may not be necessary to artificially fertilise the flowers now that there are plenty of bees at work. Feed liberally as soon as the fruits are set and thinned, never allowing the plants to become dry at the root, and a good crop of fruit will probably come on at a time when it is much needed, the early outside crop often deceiving one owing to late frosts.

Melons ripening must be given rather more air than during the growing period, but I am not in favour of withholding water at the root during the ripening process, the best-flavoured Melons being those that are liberally supplied with water till they are nearly ripe.

Hardy Fruits.

Peaches.—Continue the disbudding of Peaches on walls as the state of the growth warrants, not forgetting to keep a sharp look-out for fly, which is often troublesome in the early part of the season.

Apricots.—This latter remark *re* fly is also applicable to these, and a good syringing on a warm day will often keep it under.

Strawberries that are coming into bloom will need protection should the weather prove cold, and plenty of covering material must be at hand to cover the early bed over should it prove necessary. It is not advisable to put this covering directly on to the plants, but by running a string or wire down each row it will keep the covering material off the plants and so make it very much more effective.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Planting Antirrhinums.—The ground should be forked over and made smooth before commencing operations. Antirrhinums tell most effectively when planted in masses; much depends upon the harmonising of colours. The crimson shades and yellows should be associated with each other, while the various shades of pink and white go together. Planted a foot apart, they will entirely cover the ground.

Planting Pentstemons.—Seedlings may now be planted, and although not so reliable as Antirrhinums, they are quite useful for a mixed display. Plant at a foot apart, and be careful in lifting the seedlings, as they have rather bare, fleshy roots.

Staking.—Some of the taller herbaceous plants will now require staking and a first tying. Where there are large clumps of Delphiniums, Lupines and such like, three stakes should be given to each clump, with binder twine run round not too tightly. Strong-growing subjects should have fairly stout stakes, while slender subjects, such as the lighter forms of Aster, should have rather slender stakes. If a line of binder twine is run round a Phlox, the combined strength of the stems generally keeps them in position. Some things, such as Aster acris and Anthemis tricolora or Kelwayi, are prone to recurve unless closely attended to, more especially if they are near the shade of trees.

The Rose Garden.

Thinning the Buds.—This operation, technically known as disbudding, is a necessity to those who desire large blooms, and especially to those who contemplate exhibiting. The operation can be conveniently performed with a pair of Grape scissors. All malformed buds, or those which have been injured by insects, should first be removed. For general decorative purposes very little disbudding is necessary, and in the case of ramblers, Chinas and what are generally known as garden Roses, no disbudding is required.

The Shrubbery.

Pruning Forsythias.—Although frequently grown on a wall, Forsythia suspensa makes an admirable subject for the shrubbery, whether trained in bush form or pegged down in a clump. Owing to the lack of sunshine last summer, it has not flowered so freely as usual this spring. Now is the time to prune, and as it flowers on the previous season's wood, a considerable portion of that should be cut away.

Pruning Pyrus japonica.—This showy shrub is more or less a continuous bloomer, near the coast, at any rate. The normal flowering period being now over, this is a good time to prune, and it should not be done too severely.

Rhododendrons.—Early varieties like arboreum and noblecum should have the dead trusses removed.

Plants Under Glass.

Forced Roses.—Unless these receive careful treatment, good results cannot be expected next season. If the weather is mild, they may now be placed out of doors in some cosy corner till they barden off slightly before being put out in the open. Attend closely to watering and give a little stimulant occasionally.

Richardias.—As these go out of bloom they should be removed to the greenhouse and the supply of water gradually reduced. Keep them clear of aphids.

Chrysanthemums.—If the weather is genial, these may now be placed out of doors in a sheltered position. Some growers give them the final shift before belding out commences, while others delay the operation till the beginning of June. Unless the plants are very forward, I think the latter period is to be preferred.

Azalea indica.—These useful greenhouse shrubs should now be enjoying a little warmth in ainery till they make their growth and develop their flower-buds.

Deutzias should have the bulk of the old wood cut away, and be placed in a little heat till the young wood is made. Moderate doses of liquid manure twice a week will help to promote a vigorous growth.

Fruits Under Glass.

Mulching Peaches.—In the earliest house the fruits will now be swelling rapidly. As evaporation is now becoming more rapid, the trees will be benefited by receiving a good watering, and after the surface of the border has partly dried, stir it with a hoe, and then apply a mulching of well-decayed manure.

Tomatoes.—The latest batch should now be planted, boxed, or potted, as the case may be. Good loam with a dash of bone-meal in it is all that is necessary at this stage. Early crops swelling their fruits must be regularly fed, more especially if the roots are confined in pots or boxes. Thomson's Special Tomato Manure is very reliable.

The Fruit Garden.

Mulching.—If not already attended to, all newly-planted trees should receive a mulching to conserve the moisture and to help to maintain an equable temperature at the roots. Where the soil is rather light and porous, mulching is much to be recommended, especially in the case of stone fruits on a south wall.

The Kitchen Garden.

Thinning Crops.—This is an important operation, and should receive prompt attention. Spring-sown Onions should be thinned out to 6 inches or 8 inches apart, intermediate Carrots to 6 inches and long-rooted to 9 inches, Salsify to 6 inches, Parsnips to 12 inches, Turnip-rooted Beet to 6 inches and long-rooted to 9 inches. It will be readily understood that these distances are approximate; a good deal depends upon the variety, soil and liberality of cultivation.

Vegetable Marrows.—It is too early to plant out yet, but preparations should be made for them. A good plan is to make a slight excavation, about a yard square, towards the back of a south border, and on this a good barrow-load of manure is placed. This in turn should be covered with the soil excavated, thus forming a slight mound. This raises the temperature at the roots above that of the border.

Salading. Continue to sow successions of Lettuces, Radishes, and Mustard and Cress.

CHARLES COMFORT

Broomfield Gardens, Dr. Wilson's Mans, Middlebury.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

LAWNS (Henry).—You cannot do better than give your lawns a dressing of bone-meal at the present time; then in autumn give them a good dressing of rich soil. Bone-meal may be applied at the rate of about seven to ten hundredweights to the acre, and an inch of soil may be applied with advantage in autumn. Providing you cannot obtain rich soil, apply well-rotted farmyard manure in autumn.

HYACINTHS AFTER FLOWERING (J. G. D.).—The Hyacinths should be allowed to mature in the position in which they have flowered, when they may be lifted and dried off in an airy shed or outhouse. It is doubtful, however, if they will flower so well another year, though they may give small spikes of flowers. The single Jonquills usually flower in May, and they may be early or late, according to the conditions of the weather. It is getting a little late for sowing annuals. Mid-March would have been much more suitable for the majority of such things. Sow the seeds of the perennials at once, preferably in a prepared plot of ground in the open in a rather sheltered place. The resulting seedlings will give you nice, sturdy plants for transplanting in autumn.

TREES AND SHRUBS.

PRUNING HOLLIES (Judith).—Your Holly trees may be pruned at once if they require it, but we do not advise you to prune very severely, as the trees have been cut fairly hard during the last two years. It is a great mistake to clip Hollies so severely as to give them a great appearance. A mulch of well-rotted manure and decayed leaves will do good, but do not pile the top-dressing round the trunks; rather, keep the manure a foot away from the trunks, and let it extend to the outskirts of the branches. It is probable that you will not have so many berries next winter.

BOX SHOOTS FOR INSPECTION (Quincy).—The Box shoots sent for examination have been injured by a small insect called by scientists *Monarthropalus buxi*. The insect deposits its eggs below the epidermis of the leaf, and when the larvae hatch out they feed on the leaf-tissues and cause the yellowish galls. You can do something to diminish the attack by spraying the plants during May and June with a paraffin or nicotine solution. Such solutions prevent egg-laying to a certain extent by making the leaves distasteful. They also kill any insects which have not already escaped from the galls. The Berberis leaf sent for name is *Berberis Aquifolium* variety *murrayana*.

FLOWERING SHRUBS FOR SANDY SLOPE (F. C.).—In addition to those you name, you might plant the common Barberry, double-flowered Gorse, Flowering Currants, *Cytisus praecox*, *Berberis Darwinii* and *Weigela* in variety. It is, of course, getting rather late for planting such an exposed and steep slope, and early autumn would be much better. If you desire the perennials for the same position, we fear only the Flag Irises would do you any service. White and red perennial Peas, if planted high up the bank, would trail and look very beautiful. The Marigolds, Wallflowers, or Snapdragons, each of which would reproduce themselves from seeds, would be worthy of trial. Neither Lilies nor Gladioli would be suitable.

THE GREENHOUSE.

INDIA-RUBBER PLANT (H. M.).—Judging by the leaves sent, your India-rubber Plant appears to be, if not actually dead, at least so far gone that, however treated, it is not likely to recover. You speak of it having been for years in a cold greenhouse, and if that implies, as is generally understood, a structure without any artificial heat whatever, you are fortunate in having kept it so long, for, being a native of the East Indies, it does best in a fairly warm house. At all events, in order to keep it in health, a minimum night temperature should not fall below 45° to 50°. There is no doubt that your plant has been gradually declining in health for some time. Worms at the root might be choking the drainage, and thus, causing a sodden state of the soil, be answerable

for some of the trouble; but, as stated, we consider the main reason to be that it has been kept too cold.

SALVIA AZUREA (A. M.).—*Salvia azurea* must be treated in much the same way as *S. splendens*. At the same time, you must bear in mind that it is naturally of a taller and more slender habit of growth than the other, and consequently it cannot be formed into such bushy specimens as can be obtained in the case of *S. splendens*.

PELARGONIUM LEAVES FOR OPINION (F. S. H.).—We think you are quite right in putting down the trouble with the Pelargoniums to some wrong application of water under the conditions existing in the houses. Either too much or too little water at the time the young leaves are developing frequently causes a check from which they do not recover, and every care has to be exercised in seeing that a proper balance is maintained between the supply of water at the root and the moisture in the air, the temperature and the light.

SOIL FOR CARNATIONS (G. B.).—You will find directions as to the most suitable soil for Tree Carnations in THE GARDEN for April 19, page 198. At the same time, different cultivators employ different mixtures, with equal success. One who grows these plants remarkably well advises two parts of good loam of a holding nature, one part leaf-mould, and one part made up of equal portions of old mortar rubble and sand. With a sprinkling of bone-meal the whole is well mixed together. A good book dealing with the subject is "Carnations, Perpetual Flowering," by Laurence J. Cook, price 1s. 9d.

INJURY TO PELARGONIUM CUTTINGS (E. H. H.).—The Pelargonium cutting is attacked by the fungus *Botrytis cinerea*. This is a very common fungus on all sorts of vegetable matter, and the spores are practically ubiquitous. It attacks living plants as a rule (1) after it has been growing for a time on decaying matter in the soil; (2) when they are very sappy or have some unhealed wounds upon them; and (3) at times when they have been exposed to low temperatures. Some varieties are naturally more liable to attack than others, e.g., the white Lily is much more frequently attacked than any other Lily by this fungus, which is the cause of the Lily disease. Treatment and preventive measures in the present case lie in keeping the plants in as well ventilated a situation as possible, removing and burning all dead and decaying matter, keeping the atmosphere as dry as is consistent with the slow, steady growth of the plants, and occasionally spraying with a solution of 1oz. of potassium sulphide in three gallons of water.

ROSE GARDEN.

DISEASE ON SCOTCH BRIAR (R. F. C.).—The fungus on the Briar is the Rose rust (spring form), *Phragmidium subcorticium*. This spreads by means of the spores on the spring form to the foliage, and produces brown and, later, black spots on the lower side of the leaves. The fungus winters on the leaves, and the more completely they can be destroyed in the autumn the better, for it is from these diseased leaves that the spring infection comes. Spraying with Bordeaux mixture or with a rose red solution of potassium permanganate will help to keep the fungus in check. The disease attacks wild Roses, and so makes it difficult to keep in thorough check in the garden.

FRUIT GARDEN.

WORMS AND STRAWBERRIES (W. P.).—The worms you speak about which attack your Strawberry fruits are not likely to be wireworms, but what they are it is not possible to say without seeing them.

SILVER-LEAF ON NECTARINE (H. E. J.).—The Nectarine is suffering from silver-leaf disease. Cut out the affected branches beyond the point where the wood shows a brown stain. The disease attacks stone fruits chiefly, but spreads only from dead shoots. Trees attacked rarely recover.

APPLE WOOD FOR INSPECTION (A. J. B.).—The Apple trees are badly attacked by the woolly aphid, and probably by the canker fungus as well. It is too late now to spray them with caustic wash, but that is the best winter treatment. From now onwards they ought to be painted with methylated spirit or linseed oil wherever the white woolly matter that protects the aphid makes its appearance, working the brush well into the wounds and among the galls the pest makes.

ARTIFICIAL POLLINATION OF APPLES (G. H. N.).—To carry out the cross-pollination of Apples with any large area outdoors is very difficult and tedious, as to be sure of doing it pollen must be transferred by means of a brush from one tree to another. Pollination, as a rule, occurs naturally; but effective cross-pollination in Apples means taking pollen from the flowers of another variety altogether. The only feasible method would appear to be the removal of branches from one variety to the tree it is destined to pollinate, and the use of a rabbit's tail alternately on the flowers of the branch and of the tree.

SILVER-LEAF ON PEACH TREES (Weybridge and G. S.).—As you suggest, the Peach is attacked by silver-leaf. There seems no doubt that this disease is due to the fungus *Stereum purpureum*, which makes its way into the trees, whether they are Peaches, Plums, or Portugal Laurels, by way of wounds. The fruits of the fungus are produced only on the dead stems, and it is from these that the fungus spreads to new trees. Once attacked, branches rarely recover, and it is best to cut them out in case the disease spreads backwards, as it does to some extent. The branches should be removed so far that no brown stain can be seen in the wood, and the

wounds should be painted over with lead paint, tar, or a 2½ per cent. solution of Lycol.

YOUNG VINES NOT FRUITING (J. S.).—The young Vines are offended with you for cropping them so heavily the first year after planting, and are having their revenge by refusing to give you any fruit to speak of this year. Indeed, in their way they are laughing at you for your folly or want of experience in your treatment of them. Evidently the border is all right, and the treatment you give the Vines in the way of temperature and atmospheric moisture is also right. This is evident from the fact that the Vines have broken into growth freely and regularly this spring. As a matter of fact, you ought not to have taken a single bunch from them last year, and only about three bunches to a Vine this year if you had had the chance, six bunches the third year and a full crop the fourth year. No doubt the Vines will show plenty of fruit next year, but you must not let each Vine carry more than four to six bunches, according to their size and strength.

MISCELLANEOUS.

CLEANINGS OF FLUES FROM A DISTILLERY (G. W. O.).—We presume this would be composed of burnt ash and soot, and therefore must contain a fair amount of potash and valuable manures. The autumn is the best time to apply it, spreading it on the surface of the soil and digging it in 6 inches or 7 inches deep at the rate of a peck to the rod or perch.

FROGS AND TOADS (L. B.).—Frogs and toads are extremely useful in the garden, and eat many injurious flies and other insects and slugs. They do no harm whatever themselves, and in spite of the fact that you have a stream at the bottom of the garden, you should have no difficulty at all in keeping the frogs and toads, as there are damp spots with plenty of nooks for shelter. Toads especially would be valuable.

RAISING SEEDLINGS UNDER CLOCHES (C. E. O.).—Until the seeds are above the ground it is not necessary to ventilate the cloches, but rather to shade them during the warmest part of the day. As soon as the seedlings are above the ground, air must be admitted on warm days. This is done by tilting the glasses on one side, raising them about an inch by placing a stone under them. Remove the stone about three or four o'clock in the afternoon. It is not necessary to ventilate on cold, dull days. The cloches must be taken off while watering the seeds or seedlings.

SMALL HOLDING (G. W.).—We are not inclined to regard your scheme with much approbation, as the prospects favour the losing of your capital; but if you are a skilful grower, you would get some return. If you use all your capital on the house, how are you going to stock and maintain it, and how are you going to live until even the first crops mature? It seems to us that your best course would be to grow general crops out of doors for one season at least, and probably for two, when you should have a steady income if you can find a market. How much have you to pay for the land? How is it situated in regard to markets? What practical knowledge have you? Write again, giving full details briefly and clearly and a further reply will be sent.

HORTICULTURAL SCHOLARSHIPS (R. F. C.).—Some of the County Councils offer scholarships in horticulture in their own institutions or in those in adjacent counties, and these are either free or assisted. In other counties, and apparently in your own, no such provision is made. Agriculture is far better served in this direction. One or two scholarships are annually offered by the Worshipful Company of Gardeners on the results of the General Examination in Horticulture held by the Royal Horticultural Society. A syllabus and particulars of this examination can be obtained of the Secretary, Royal Horticultural Society's Hall, Vincent Square, Westminster, S.W. The Royal Horticultural Society also maintains a school for young men over sixteen at its gardens at Wisley, Surrey, where thorough instruction is given in both the principles and operations of horticulture; and other schools are in connection with the University College, Reading; Holmes Chapel College of Agriculture, Cheshire; and Uckfield Agricultural College, Sussex. Excellent short courses are given in the County Institute of Agriculture, Chelmsford.

LICHEN ON TREES AND SHRUBS (Mrs. C.).—A humid atmosphere, particularly if it be accompanied by a stagnant condition of the soil, is very favourable to the growth of lichen. In some parts of Ireland it prevails to a considerable extent, and we have at different times had numerous examples from that country. It is unfortunate that you have delayed the enquiry till growth is commencing, as in order to destroy the lichen it must be taken in hand while the shrubs are quite dormant. Various remedies have been tried, but the one that meets with the most favour is to spray the affected plants with the caustic soda wash as used for fruit trees. It must be carefully applied and the hands protected with rubber gloves, as it is of a burning nature. Some forms of *Stephanotis* flower more freely than others, and if plants are raised from seeds they will often cover a considerable space before they bloom. As your plant is in a pot, you will be able to limit the water supply, and if you have been giving stimulants, we should advise you to discontinue them. Then, if it does not bloom this season, see that it gets a good amount of sunshine during the latter part of the summer and in autumn, and then during the winter keep the soil dry. With this treatment it will, under the influence of increased heat and moisture, probably flower next spring or summer.

NAME OF PLANT.—*G. Killick.*—*Bryophyllum calycinum*.

SOCIETIES.

THE MIDLAND DAFFODIL SOCIETY'S SHOW.

The fifteenth annual exhibition in connection with the above society was held in the Botanic Gardens, Edgbaston, Birmingham, on Tuesday and Wednesday, the 22nd and 23rd ult. The show was opened by the Lady Mayoress, who was accompanied by the Lord Mayor. Competition was exceedingly good, no less than six groups being staged in the large class for fifty varieties. A promising sign also was the number of seedlings shown by amateurs. The arrangements, as usual, were excellent, and reflected the greatest credit on the secretary, Mr. H. Smith, and the committee. In the evening, Mr. Robert Sydenham very kindly entertained the exhibitors, judges and visitors at dinner at the Grand Hotel, after which the Rev. G. H. Endeheart opened an interesting discussion on the cultivation of Daffodils.

GROUP A.—CUT BLOOMS (OPEN).

Class I was for a collection of fifty varieties of Daffodils, representing as far as possible the different divisions. Six exhibits were staged in this class, the premier position being filled by the Rev. J. Jacob, Whitwell Rectory, Whitchurch, Salop, with a beautiful collection of flowers. A few that we specially admired were: H. C. Bowles, a giant Leedsii with large fluted cup; Charlotte, Olympia alba, a large white trumpet; Horace, Lady Moore, a lovely flower, with large orange, scarlet-edged cup, and The Fawn. Second honours fell to Messrs. Cartwright and Goodwin, Kidderminster, who also staged a fine lot of flowers, among them being such sorts as Enterprise, Trojan Boy, a beautiful giant Leedsii; Ethereal, Lord Kitchener, and Orangeman. Mr. C. Bourne, Bletchley, was a good third, having some superb flowers of Queen of Hearts in the centre of his group. Mr. J. Pope, King's Norton, was fourth.

Class 2 was for a decorative exhibit of cut Narcissus only, arranged in a given space. This was the most artistic class in the show, and made quite an interesting feature. Mr. C. Bourne was a good first, with a beautifully arranged exhibit, his vases of Poets being particularly pleasing. Mr. J. Pope, King's Norton, was second, and the Rev. J. Jacob third.

In Class 3, for six distinct varieties of trumpet Daffodils (yellow), there were five entries, Mr. W. A. Watts, St. Asaph, being first, with splendid blooms, four of which were seedlings. The Rev. J. Jacob was a good second, his King Alfred and a fine seedling calling for special mention. Mr. W. A. Milner, Totley Hall, Sheffield, was third.

In a similar class for white trumpets there were only two entries, Mr. W. A. Watts being again placed first. His Bevan and Mme. de Graaf were superb. Mr. J. Mallender, Bawtry, was second, his vases of La Bonnia and Sybil Foster being superb.

For six tricolor Daffodils, distinct, Mr. W. A. Watts was again first out of four competitors. His vase of Armin, a superb, long, cream trumpet variety calling for special mention. The Rev. J. Jacob was second, Olympia alba being his best variety. Third and fourth prizes went respectively to Mr. J. Mallender and Mr. J. Pope, King's Norton.

For six varieties of incomparabilis, Division 2A, there were only two entries, Mr. W. A. Watts being first and the Rev. J. Jacob second. The flowers in this class were rather poor. In a similar class, but Division 2B, the Rev. J. Jacob and Mr. C. Bourne were equal firsts, both staging a very fine lot of flowers. Mr. Jacob's Whitwell and Mr. Bourne's Tritoma calling for special mention. The third and fourth prizes went respectively to Mr. W. A. Watts and Mr. J. Pope.

For six distinct Barris, Division 3A, there were only two entries, first and second honours going respectively to Mr. W. A. Watts and the Rev. J. Jacob, both of whom staged very clean flowers.

In a similar class, but Division 3B, Mr. C. Bourne was first out of five competitors, putting up fine vases of Red Eye and Ethelbert. Mr. F. H. Chapman, Rye, was a good second, his flowers of Captain General, Javelin and Glad Eye calling for special mention. Third, fourth and fifth prizes went respectively to the Rev. J. Jacob, Mr. J. Pope and Mr. W. A. Watts.

For twelve distinct varieties of Leedsis, three stems of each, there were four entries, the Rev. J. Jacob being first with a beautiful lot of flowers. Endurance, Last Out and Lord Kitchener were three favourites. Mr. C. Bourne was a close second, his Little Joan and Silver Spangle attracting much attention.

In Class 11, for three distinct varieties of triandrus hybrids, Mr. W. A. Watts was first out of three competitors, staging Dewis, Clyn and a seedling. Messrs. Cartwright and Goodwin were a good second with Josette, Chloë and a seedling. Mr. C. Bourne was third, his vase of Lemon Belle being very clean and good.

For six distinct varieties of Tazetta and Tazetta hybrids, Messrs. Cartwright and Goodwin, Kidderminster, were first with fine examples of Elhura, Klondyke, Jaune à Merveille, Ideal, Orient and Irene. Third prize went to the Rev. J. Jacob, who had a fine vase of Orange Blossom.

For nine distinct varieties of true Poeticus there were five entries, Mr. C. Bourne being first with a beautiful lot of flowers, among which we specially noticed Homer, Laureate and Horace. Messrs. Cartwright and Goodwin followed closely, the third, fourth and fifth prizes going respectively to Mr. F. H. Chapman, Mr. W. A. Watts and the Rev. J. Jacob.

In Class 14, for twelve distinct varieties of original species and natural hybrids, there was only one exhibit,

this coming from Mr. Bruce Waite, 92, Carless Avenue, Harborne, who had some good flowers.

Single Blooms.—The first prizes for these were awarded as follow: Yellow trumpet, Mr. W. Welchman, Upwell, Wisbech, with The Commonwealth; white trumpet, Mr. A. M. Wilson, Bridgwater, with White Knight; bicolor trumpet, Mr. A. M. Wilson, with a large seedling; incomparabilis (Division 2A), Mr. A. M. Wilson with a seedling; incomparabilis (Division 2B), Mr. A. M. Wilson with Centurion; Barris (Division 3A), Mr. A. M. Wilson with a seedling; Barris (Division 3B), Mr. C. Bourne, Bletchley, with Queen of Hearts; Leedsii, Mr. Ridley, Wincanton, with Moonbeam; triandrus hybrid, Mr. W. A. Watts with a large seedling; Jonquilla hybrid, Mr. P. D. Williams with a seedling; Tazetta or Tazetta hybrid, Messrs. Cartwright and Goodwin with Jaune à Merveille; true Poeticus, Mr. H. G. Hawker, Ivybridge, Devon, with Dulcimer; and double, Mr. J. Pope with Golden Rose.

For the Bourne Challenge Cup, offered for a group of twelve distinct varieties of Daffodils that have been raised by the exhibitor, there were two entries, Mr. E. M. Crossfield, Cossington, Bridgwater, being first with a beautiful lot of flowers. Ibex, Orb and Nomad were three exquisite Poets, Dell, Winsome and Ringdove being others that attracted much attention. Mr. W. Welchman, Upwell, Wisbech, was second with a dozen trumpets, Lord Cromer (rich yellow) and Lord Lister (bicolor) calling for special mention.

In Class 30, for a group of seedling Daffodils that have been raised by the exhibitor and are not in commerce, there were fifteen entries, Mr. A. M. Wilson, Shovel, Bridgwater, being first, his flowers including some exquisite unnamed Poets. Second prize fell to Mr. W. A. Watts, St. Asaph, Mr. J. Pope and Mr. F. H. Chapman following in the order named.

In the following class, which was similar, except that only three varieties were asked for, there were no fewer than eleven entries, Mr. P. D. Williams being a good first. A seedling with a rich scarlet eye and apricot perianth, and Susan, with a green eye, were much admired. Messrs. Cartwright and Goodwin, Mr. C. H. Cave and the Rev. T. Buncombe followed in the order named.

In the novice seedling challenge class, for three distinct varieties of Daffodils raised by the exhibitor and not in commerce, Mr. N. Y. Lower, Prestegon, was first out of ten competitors, staging three very good seedling Poets. Mr. C. L. Adams, Penderford Hall, Wolverhampton, was second; Mr. W. Wilson, jun., Holmesfield, Sheffield, third; and Mr. J. Simkins fourth.

For the Cartwright Challenge Cup, offered for a group of twelve distinct varieties of Daffodils that have not been in commerce more than four years, there were two entries, Mr. E. M. Crossfield being a good first, his Poets, particularly Orb, Ring Dove and Dick Turpin, calling for special mention. Messrs. Cartwright and Goodwin were second with a beautiful lot of blooms.

In a similar class for six varieties, Mr. C. Bourne was first out of four competitors, his blooms of Miss Willmott and Queen of Hearts being very fine. The Rev. J. Jacob was second, Lady Moore being his best flower. Mr. H. D. Phillips, Mulverle, Olton, and Mr. W. A. Watts were third and fourth respectively.

In a similar class for three varieties, Mr. H. G. Hawker, Ivybridge, Devon; the Rev. T. Buncombe, Black Torrington, Devon; Mr. F. H. Chapman and Mr. J. Pope won in the order named.

For the Herbert Chapman Poeticus Trophy, for a group of six distinct true Poeticus that have not been in commerce more than four years, including at least one variety not yet in commerce, Mr. E. M. Crossfield was a good first, his blooms of Sarchedon, Caesar and Millie Price being particularly good. Mr. A. M. Wilson was second and Mr. C. Bourne third.

For the Walter Ware Challenge Cup, offered for a group of eighteen distinct triandrus hybrids, Mr. W. A. Watts was the only exhibitor, and at the request of Mr. Ware the cup was awarded to this exhibitor.

GROUP B.—CUT BLOOMS (OPEN TO AMATEURS ONLY).

In Class 38, for six distinct varieties of Daffodils that have not been in commerce more than four years, there were three entries, the first prize falling to Mr. N. Y. Lower for a good lot of flowers. The Rev. T. Buncombe was second, and Mr. T. Batson third.

In Class 39, for a collection of twenty-four distinct varieties of Daffodils, there were no fewer than eight entries, the first prize being allocated to Mr. E. H. Wood, Ludlow, for a very fine lot of blooms, Sunrise and Red Chief calling for special mention. Mr. N. Y. Lower was a good second, Lucifer and Red Chief being two of his best. Mr. J. A. Kenrick, Harborne; the Rev. T. Buncombe; and Mr. R. Bruce Waite, Harborne, followed in the order named.

For nine distinct varieties of trumpet Daffodils, three stems of each, there were seven entries, Mr. J. A. Kenrick, Harborne, being a good first with very clean flowers. Mr. E. H. Wood, Ludlow, was second.

In the type classes for three distinct varieties, the first prize winners were as follow: Incomparabilis, Division 2A, Mr. N. Y. Lower; incomparabilis, Division 2B, Mr. E. H. Wood; Barris, Division 3A, Mr. T. Batson; Barris, Division 3B, Mr. T. Batson; Leedsii, Mr. N. Y. Lower; Tazetta and Tazetta hybrid, Mr. J. A. Kenrick; true Poeticus, Mr. E. H. Wood; double, Mrs. Gumbleton, Tewkesbury.

In Class 49, for twelve distinct varieties of Daffodils, three stems of each, there were five entries, Mr. A. Taylor, Olton, being first with some beautiful flowers. Mr. R. Bruce Waite was a good second.

GROUP C.

This section was open only to those who have never won more than three first prizes at any of the society's

exhibitions. The first prize winners were as follow: For twelve distinct varieties, Mrs. Ridley; six distinct varieties of trumpets, Mr. E. Winchester; six distinct varieties of incomparabilis, Mr. A. Taylor; six distinct Barris, Mrs. Ridley; three distinct Leedsis, Mr. W. F. Mitchell; three distinct varieties of Tazetta and Tazetta hybrids, Mr. E. Deakin; and three distinct varieties of true Poeticus, Mrs. Ridley.

NON-COMPETITIVE EXHIBITS.

Robert Sydenham, Limited, Birmingham, staged a fine and comprehensive group of Narcissus, the whole of the flowers being clean and well set up. Among a few that called for special mention were Whitwell, Tinsel, Red Chief, Will Scarlett, Ethelbert, Firebrand, Evangeline, Red Beacon, Miss Bentinck and King Alfred. The same firm also showed some Tulips, Lily of the Valley and other plants grown in fibre. Silver-gilt medal.

Messrs. J. R. Pearson and Sons of Lowdham, Notts, put up a very effective group of high-class, well-grown flowers, the staging being of the usual high order. Virgil, Scarlet Eye, Norah Pearson, Florence Pearson (a beautiful white trumpet), Advance (a deep, red-eyed Poet), Heroine, Lowdham Beauty (fine giant Leedsii), Gipsy Queen, Croesus and Homer were a few among many that called for special mention. Silver-gilt medal.

Mr. Christopher Bourne, Simpson, Bletchley, staged a small group of beautiful Daffodils, these embracing many of the latest varieties. Among those that were most admired were Queen of Hearts, Undine, Red Eye, Horace, White Lady and Dewdrop. Mr. Bourne also had a collection of well-grown Tulips, such varieties as Mrs. Moon, Mr. Farnecombe Sanders and La Tulip Noire calling for special mention. Silver medal.

The group of Daffodils staged by Messrs. Cartwright and Goodwin, Kidderminster, was, as usual, of a high order, the flowers all being clean and well grown. Particularly noticeable were Orangeman, Whitwell, Target (with a vivid orange red cup), Southern Star, Emerald Eye (a beautiful flower with large flat cup and vivid green eye), Evangeline, A. D. G. Johnson (with bright red eye) and Horace. Silver medal.

Baker's, Limited, Wolverhampton, put up a fine rock garden exhibit in their usual position. The plants shown were all in good condition, and were well arranged. Among many good plants that called for special mention were Dianthus cesius Baker's variety, a fine lot of Ranunculus amplexicaulis, Saxifraga's Red Admiral and bathoniensis, Arabis aubrietoides, Incarvillea grandiflora, Erinus hirsutus and E. alpinus albus. Silver-gilt medal.

Messrs. Barr and Sons, King Street, Covent Garden, had a lovely group of Daffodils, all the latest and best varieties being staged in an admirable manner. Among a few of many good things were Anchorite, Rosy Morn (a very beautiful flower, with scarlet eye and apricot pink perianth), Gladiator (a very large, flat-cupped variety, with rich yellow centre and a broad band of orange scarlet), Moonbeam (white, flat cup, delicate yellow eye), Sarchedon (a lovely Poet), Red Rover, Snow King and Socrates. Messrs. Barr also put up a superb lot of unnamed seedlings. Gold medal.

Messrs. K. H. Bath, Limited, Wisbech, staged a beautiful lot of Daffodils and also a fine lot of Tulips, the latter growing in Cocoon fibre without drainage. Among the Daffodils we noted such as Marie Hall, Whitwell, Refulgence, Evangeline, Diogenes, Will Scarlett, Heroine, Star of the East and Laurette. The Tulips included such beautiful varieties as King Harold, Erguste, Isis and the Rev. H. Ewbank. Silver medal.

Messrs. E. R. Cant and Sons, Old Rose Gardens Colchester, staged a beautiful group of Roses, many of the flowers being equal to those seen at a summer show. Such varieties as Rose du Barri, Fortune's Yellow, Sunbeam, Richmond, Claudius and Antoine Rivoire called for more than usual praise. Silver-gilt medal.

Mr. S. Mortimer, Knowledge, Farnham, Surrey, put up a fine bank of Carnations and Stocks in pots. The latter were the variety All the Year Round, the large, white flowers emitting a delightful fragrance. The Carnations, which included all the best varieties, were well up to Mr. Mortimer's high standard of excellence. Silver-gilt medal.

Messrs. Sutton and Sons of Reading made a beautiful display with Cinerarias and forced vegetables. The Cinerarias embraced the large-flowered and stellata types, many beautiful art shades being among them. The vegetables included such kinds as Peas, Beans, Mushrooms, Asparagus, Turnips and Cauliflowers, the whole being splendidly staged. Silver-gilt medal.

Mr. H. N. Ellison, West Bromwich, staged a beautiful bank of Ferns, which provided a cool and welcome change to the more showy flowers. These embraced such kinds as Nephrolepis, Adiantums, Polypodiums, Pterises and Osmundas, the whole being in perfect condition. In the centre of the group we noticed some excellent plants of Phoenix Robelinii, an excellent Palm for the dwelling-house. Silver medal.

Mr. Vincent Slade, Staplegrave Nursery, Taunton, put up a good collection of Pelargoniums, the bright flowers making a fine feature in the sunshine. All the latest varieties were included, the whole being well grown and of good constitution. Silver medal.

Mrs. Backhouse, Sutton Court, Herefordshire, had an interesting little collection of unnamed seedling Narcissus, among them being a charming little flower with deep scarlet eye and pale apricot perianth, and also several Poets with pale apricot eyes. Silver medal.

Messrs. Ramshoburn and Co., Geashill, King's County, Ireland, had a fine bank of their world-famed double St. Brigid Anemones, the large flowers and brilliant colours being concrete examples of high-class cultivation. Silver medal.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

*The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.*

Office: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Our Rock Garden Competition.—Full particulars of our competition for photographs of the best rock garden appeared in our issue for last week. We would remind all those who intend entering that June 1 is the last day for sending in photographs.

Trials of Spraying Apparatus.—The results of the trial of spraying apparatus held by the Royal Horticultural Society at Wisley on the 23rd ult. have now been published. We hope to give an illustrated report of the trials in our next issue.

Removal of Seed-Vessels from Bulbs.—Hyacinths and Daffodils, like most other plants, greatly benefit by the removal of the seed-pods as soon as the flowers have faded. If these are left on, the developing of the seeds takes up a lot of nutriment that would otherwise go towards building up the bulb for another year. Do not, however, make the mistake of removing foliage also.

The Dwarf or Russian Almond.—This is a pretty dwarf Almond, forming a nice bush 2 feet to 4 feet high, and is a native of Southern Russia. The rose-coloured blossoms are freely produced during April. There is a white variety named *alba* and a rich rosy red form named *rubra*. Layering forms an easy and ready means of increase. The dwarf Almond is variously known in gardens as *Prunus nana* and *Amygdalus nana*, forming the subject of a figure in the *Botanical Magazine*, t. 161, under the second name.

The Chelsea Flower Show.—We understand that the Royal Horticultural Society's Spring Show, which is this year to be held in the Royal Hospital Grounds, Chelsea, instead of the Inner Temple Gardens, promises to be a record one. Arrangements are already well in hand, and the crush which has characterised the Temple Show in recent years is not likely to occur. The show opens at 12 noon on Tuesday, May 20, and closes at 6 p.m. on Thursday, May 22. This exhibition is rightly regarded as the flower show of the year.

The Queen at Kew.—The Queen visited the Royal Gardens at Kew on Wednesday, the 30th ult., making a tour of the outdoor garden from the Main Gate, through the Rhododendron Dell, to the Bluebells in the Queen's Cottage Grounds. There on either side of the central path the Bluebells are a sea of blue, which is broken only by the trunks of the trees under which they grow. Of late years openings have been made among the Brambles and other undergrowth, so that wide areas of flowers are now shown which were previously hidden.

Caltha palustris semi-plena.—In this plant we have a bold yellow-flowered Marsh Marigold for the side of the pond or stream or the bog garden, and many will admire it who do not care for the

several double varieties, and who have the wild single form in plenty in their districts and so do not plant it in the garden. This variety has all the charm of the glossy leaves and brilliant gold of the wild plant, but the flowers, which are large, are semi-double. They are thus more lasting than those of the single form, but are much less heavy than the doubles, such as *C. palustris* fl.-pl., *C. p.* fl.-pl. *monstrosa*, or *C. p.* fl.-pl. *minor*. There is no difficulty in cultivating it in moist soil.

Does it Pay to Spray Potatoes?—Potato-growers have long asked this question. It is well known that in seasons when blight is destructive, spraying will check the blight and considerably increase the yield of tubers; but many Potato-growers have doubted that spraying is profitable on the acreage. According to a report just published from the New York Agricultural Experiment Station, a long series of experiments demonstrate beyond doubt that the spraying of Potatoes is highly profitable in the neighbourhood of that city. The report goes on to say that spraying with Bordeaux mixture should be commenced when the plants are 6 inches to 8 inches high, and repeated at intervals of ten to fourteen days throughout the season.

***Cytisus fragrans* Growing Outdoors.**—Although it is usual to associate this Canary Island Broom with greenhouses and markets, the owners of gardens situated in Devonshire and Cornwall plant it in the open ground as people in less-favoured localities do the common and Portuguese Brooms, and it forms a handsome specimen; in fact, those who have only known it as a pot plant can scarcely imagine to what proportions it grows. Specimens 6 feet to 8 feet high are not uncommon, and when they bloom, often during February and March, they are very conspicuous, for every shoot bears racemes of golden, fragrant blossoms. In some gardens, too, the finer variety, *elegans*, may also be noted, although it must be considered a rarity. At Penzance, the garden of Mr. R. Fox, a very fine example of *C. fragrans* is to be seen.

The Spring Rose Show.—It is with considerable pleasure that we are able to announce that the National Rose Society's first spring show, held in London on Thursday of last week, and a report of which appears on another page, was an unqualified success. For several years past we have advocated the holding of such a show, because the cultivation of Roses under glass is now very much more widely adopted by amateurs than was the case a few years ago. An exhibition such as that to which we refer has considerable educational value in bringing before the public the varieties most suitable for growing under glass. We would warn our readers, however, against purchasing indiscriminately for outdoor cultivation some of the Roses that were shown. The majority would do well, but some, such as Lady Hillingdon, would in most districts prove intensely disappointing in the outdoor garden.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Berberis verruculosa.—I regret that, through a clerical error, miniature plants of this handsome Barberry were mentioned by me under the name of *B. verniculosa* on page 202, April 26. The mistake would not have occurred had not the plants been so small that their identity with *B. verruculosa* could not be established, although great care was taken. *B. verruculosa* is one of the introductions of Messrs. James Veitch and Sons, Limited, Chelsea, through Mr. E. H. Wilson, and was offered in the autumn of 1911. It is hardy in the Coombe Wood Nurseries of that firm, and grows about two feet high eventually. The flowers, which are followed by purple fruits, are yellow, as mentioned before. Miniature plants such as those described would be exceedingly pretty even on small rockeries.—S. ARNOTT.

Pear Magnate.—I send some photographs of an espalier of Pear Magnate. I think Magnate is a very fine Pear, in flower as well as in appearance, but Messrs. Bunyard have dropped it out of their list. When I asked Mr. Bunyard why, he said it was such a shy bearer. This tree is more crowded with blossom than any other in the garden, perhaps more than any I have ever seen. Unluckily, the photographs are only by amateurs, and were taken just a week too late for the blossom to be at its best; but if they are capable of being printed, they will retute this calumny against Magnate. The pyramid is Williams' Duchesse, and was supplied by Baltet. It very closely resembles Pitmaston Duchess, but is not, I think, quite identical. Moreover, Pitmaston Duchess was not, I believe, raised by Williams.—G. E. JEANS, *Shoewell Vicarage, Isle of Wight*. [Unfortunately, the photographs were not sharp enough for reproduction.—ED.]

Treatment of Disease in Plants.—I was extremely interested in Professor Houston's excellent article on this subject which appeared on page 215 of last week's issue. The methods of prevention described by him, if they could be adopted on a practical scale, would prove an immense boon to fruit-growers. I hope we shall have more particulars from others who have investigated the silver-leaf disease.—G. M.

Investigation of Pea Thrips.—May I, through your columns, ask for assistance in an investigation into the Pea thrips? Notes on the presence or absence of the pest in all parts of the country are required, and specimens if possible. If those willing to help will communicate with me, particulars will be sent. Correspondents are specially required in the South-Western Counties and Ireland.—C. B. WILLIAMS, *The John Innes Horticultural Institution, Merton, Surrey*.

The Preservation of Primroses.—Is it not true that something was done to prevent the destruction of the charming Primrose which goes on so wantonly at this season in many country districts? In a number of localities where the flower abounded within the memory of many who are still living not a plant is now to be found. The uprooting of flowering plants by itinerant vendors is, I am sure, one of the main causes of its disappearance. It is true that in country places far removed from large towns the Primrose still flourishes in abundance, but even in these haunts it is in danger.—P. R.

How to Grow Saxifraga burseriana.—In reference to the note by "Alpinist" in your issue for

will bear me out when I say that it there luxuriates in limy silt in a very deep and sunless gorge." But in spite of my debt of gratitude to Mr. Farrer for "taking me with him," I cannot honestly bear him out in all that he says. My recollection is that the plant grew in screes rather than silt, and that there was a very considerable amount of sun in the gorge. However, as Mr. Farrer's impression was of a sunless gorge, and mine of a sunny one, what conclusion is one to come to? Shall we put it down to the effect of our respective dispositions on each other at the moment? To me the whole aspect of the plant seems to indicate that it is a sun-lover. I have only grown one plant in shade, on the

north side of a low rock, and it has flowered very poorly. I have several varieties, including Gloria, planted out on granite moraine in fullest sun, without a vestige of shade at any time of the day, and these all flower magnificently. The illustration of *S. burseriana* Gloria in Mr. Farrer's little book, "The Rock Garden," represents a group of the plant which I exhibited at the Royal Horticultural Society's Bulb Show in 1912. These plants were grown in very gritty loam (in pots) plunged in sand in cold frames, which were left open and without shade the whole of the previous summer and autumn, when they were making their growth and preparing for their 1912 crop of flowers. On one point I feel sure Mr. Farrer and I cannot fail to agree, and that is the amount of sun we had in England in the summer of 1911. And those plants of *S. b. Gloria* received not only the full direct glare of the sun from overhead, but probably a good deal of reflected heat from the back of the frame as well. Needless to say, they were watered during all this sun-baking. My own opinion is that to get the best results from *S. burseriana* and its varieties, one should grow it in light, gritty loam in full sun and maintain cool moisture at the roots. Drainage, of course, is essential. This cool moisture at the roots is most easily secured by mixing a large proportion of stone chips in the soil, and giving a top-dressing of the same stone on the surface. When this is done, overhead watering is required at much less frequent intervals than when no stone is used. In "The Rock Garden" Mr. Farrer describes *S. b. Gloria* as having green flower-stems. This puzzles me a good deal, for my own plants—the original stock came from Mr. Farrer—invariably have reddish stems. Can this be due to the larger amount of sun that my plants receive? I should be greatly interested to know whether all the *S. b. Gloria* grown by Mr. Farrer have come from one original plant collected by himself, or whether he imported the original stock and subsequently collected the variety in the Schlern Klamm. The story of the discovery of this superb variety from Mr. Farrer himself would, I feel sure, be of interest to more alpinists than myself.—CLARENCE ELLIOTT.

TEA ROSE LADY FLYMOUTH. A NEW VARIETY SHOWN BY MESSRS. ALEX. DICKSON AND SONS AT THE SPRING ROSE SHOW LAST WEEK. COLOUR, DEEP CREAM, SUFFUSED APRICOT.

April 19, this Saxifrage will thrive either in full sunshine or partial shade; but it prefers the sun, and a south aspect suits it admirably. Excessive dampness is a great enemy to this plant; therefore the drainage must be perfect. It seems quite at home in a loamy soil with an abundance of grit and some sandstones. It is also worth growing as a pot plant in the cool greenhouse, as it there makes a handsome plant and flowers quite a month earlier than out of doors.—J. BROWN, *Babunoch, N.B.*

—In writing of the requirements of *Saxifraga burseriana* on page 202, April 26 issue, Mr. Farrer says: "Mr. Elliott, whom I took with me for our first sight of the plant in one of its localities,

Anehusa italica Dropmore as a Pot Plant.—I should like to point out what a beautiful subject this is for anyone having a moderately large and light, cool house. We put some plants in pots early in February, and they started to bloom at the beginning of April. They grow in any kind of soil and need no forcing. As growth advances and they make large plants they require a good deal of water. We have some single crowns in 6-inch pots, and they are very nice, but the best are those with three or four plants in 8-inch and 6-inch pots. They get no taller than when grown outside, and with a thin stake to each shoot make beautiful plants.—E. SMITH, *The Gardens, Springfield, Alderley Edge.*

Galega Hartlandii from Seeds. Although not specially fond of variegated-leaved plants, I have always had a liking for *Galega Hartlandii*, not only because of its very beautifully variegated foliage, which comes such a nice silver and green in spring and retains most of its variegation for a long time, but also because it was sent me by the late Mr. W. Baxlor Hartland himself. The possession of *G. Hartlandii* and of the handsome trumpet Daffodil raised by him and given his name always reminds me, if reminder were needed, of that genial flower-lover of the Emerald Isle. I am writing this, however, to point out that *G. Hartlandii* produces variegated plants from seeds. Some are green-leaved, but a large proportion are as finely variegated as the original. I have some very pretty self-sown seedlings in my garden, all delightfully variegated. One may add that *G. Hartlandii*, unlike many other plants with variegated leaves, flowers freely, and is pleasing with its lavender blue and white blooms.—S. ARNOTT.

The Fifty Best Alpines.—Being only a beginner and my small rockery scarcely eleven months old, I feel I have no right to join those who have been giving lists of the fifty best rock plants; but by writing out a list of my favourite fifty it may interest other beginners. The following are all looking well and doing their duty on my rockery in sun or shade: *Acantholimon glumaceum*, *Androsace carnea*, *A. lanuginosa*, *Arenaria montana*, *Auricula Large Yellow*, *Asperula hirta*, *Campanula garganica*, *C. erinus*, *C. portenschlagiana*, *C. G. F. Wilson*, *C. pulla*, *C. pusilla alba*, *C. pulloides*, *C. turbinata*, *Dianthus alpinus*, *D. neglectus*, *Cyclamen europaeus*, *Erigeron mucronatus*, *Gentiana acaulis*, *G. verna*, *Geranium cinereum*, *Haberlea rhodopensis*, *Hypericum polyphyllum*, *Iris cristata*, *I. pumila cyanea*, *I. p. Florida*, *Lithospermum prostratum*, *Lychnis Lagasca*, *Mimulus alpinus* (cardinal red, 4 inches, Bees' stream), *Oenothera eximia*, *Phlox stellaria*, *P. subulata The Bride*, *P. s. Vivid*, *Primula elusiana*, *P. cortusoides*, *P. hirsuta*, *P. involvcrata*, *Munroi*, *P. villosa*, *Saxifraga aizoon lutea*, *S. A. rosea*, *S. Grisebachii*, *S. longifolia*, *S. Elizabethae*, *S. Stormonth's variety*, *Sedum dasyphyllum*, *Sempervivum arachnoideum*, *S. triste bicolor*, *Soldanella alpinus*, *Spiraea crispifolia* and *Viola graecis*. Besides these I have had several Crocuses, *Fritularias* and *Romuleas*, all in full flower.—M. W. STUBBS, *Wells, Somerset.*

FORTHCOMING EVENTS.

May 12—United Horticultural Benefit and Provident Society's Meeting. British Gardeners' Association's Annual General Meeting at Birmingham.

May 14—Royal Horticultural Society's Meeting and Tupp Show. East Anglian Horticultural Club's Meeting.

THE ROSE GARDEN.

SOME DISEASES OF THE ROSE.

SOME three or four hundred different species of fungi are recorded in books as attacking the Roses of different species scattered over the northern hemisphere; but, fortunately, only four of them need be at all commonly the causes of really serious trouble and anxiety to the Rose grower. The diseases they produce are too well known, at least by name, to every Rose-grower; but possibly the symptoms are not quite so well known, and the Editor, ever alive to the needs of garden-lovers, has suggested that an article dealing with them would serve to forewarn and so to forearm the grower against the attacks of his insidious foes.

What is Disease?—Perhaps it is necessary to point out that the fungus is not the disease, but

ROSE SHOOT AND LEAF ATTACKED BY MILDREW.

its attack sets up a condition of disease by (1) crippling the foliage and in other ways interfering with the normal performance of the life-work of the plant, (2) robbing the plant of food intended for its own use and needed for its own development, and (3) forming poisons which destroy or damage little or much of the host's tissues. It is quite clear that wrong methods of cultivation, *i.e.*, failure to provide the proper environment for the plant, will also cause disease; but there is one great and important difference between diseases due to the attacks of fungi and those solely due to imperfections in the inanimate environment, and it lies in the contagious character of the former.

Dissemination of Disease.—Canker is as catching as measles, rust as infectious as whooping-cough, black spot as contagious as smallpox, and mildew as catching as a cold. Like these human diseases, those of the plant may pass over individuals, and even whole races may be comparatively immune. Like them, too, the condition of

the prospective victim and the nature of its environment, which so much determine his condition, to a great extent determine whether or not the plant shall succumb to their attacks.

The Value of Sturdy Plants.—If one wishes to keep a plant free from disease, one must keep it in health, which is to say, plants really healthy rarely (not *never*) fall victims to the attacks of fungi. The first principle, then, is to see to it that our plants are grown so as to be sturdy and strong; open to the light and air and sheltered from cold draughts, but not in a closed-in space so that air has no free circulation; in soil well drained and sweet, moist, but not so as to encourage the development of sappy growth; rich in plant foods, but not overrich in nitrogenous matter.

Prevention Better than Cure.—The next point to remember in dealing with diseases caused by fungi is that when once damage has been done, say, to a leaf, actual cure is impossible, *i.e.*, the particular leaf damaged cannot be repaired, though the plant may develop new foliage in its place. So all our efforts must be, when once the attack has begun, towards prevention of its spread. Thus we come to the bed-rock fact "Prevention is better than cure," and may consider what preventive measures to adopt in dealing with these four diseases, beginning with the most virulent.

Mildew.—The fungus giving the mildewed appearance grows outside the plant, merely sending suckers into it to obtain nourishment. Hence its presence is quite evident and it may be detected by careful observation at its first onset. It attacks all the growing parts, causing the leaves to become curled and incapable of performing their functions. The curling is often worse than is seen in the illustration. Shoots and buds are also attacked. The powdery appearance of the mildewed leaves is due to the presence of myriads of spores, each capable of reproducing the fungus in a fresh centre. As the fungus is itself on the outside of the plant, it may be killed by suitable applications, and either plentiful dusting with flowers of sulphur while the leaves are damp with dew or spraying with sulphide of potassium (liver of sulphur) at the rate of 1oz. to three gallons of water will be the best means of accomplishing this. If tough-leaved varieties, like some of the Hybrid Perpetuals, are to be sprayed, the liver of sulphur may be used at the rate of 1oz. to two gallons of water. It is important to note that mildew is always most virulent when the Roses have received a check, as by drought or cold winds or a water-logged condition of the soil. Shelter from draughts and good drainage, combined with a dust mulch formed by a hoe, will do much towards avoiding attack, and at the same time, where mildew is prevalent, choice may be made of those varieties which, in the particular district, resist the attacks of mildew best. Probably no varieties are perfectly immune, but some are less prone to attack or suffer less from it when it comes than others.

The fungus passes the winter on the shoots in the form of felted webs of greyish threads, which are well shown in the illustration. Occasionally, though rarely in this country, a very resistant form of fruit is developed; but in any case it is from these centres that infection spreads on to new growth, and pieces of stem affected should be pruned out and burned during the winter or spring pruning. The fungus causing the Rose mildew (which does not attack many other species of plant) is called, on account of forming this felt-like growth *Sphaerotheca pannosa*.—E. J. CHILDEN.

(To be continued.)

THE FLOWER GARDEN.

DAFFODIL NOTES.

THE MIDLAND SHOW.

AS the Editor was present himself at Birmingham and a full report of the show appeared last week, there is no need for me to make many general remarks upon the show. Perhaps as one of the competitors I may be allowed to congratulate Mr. Herbert Smith, our secretary, and Mr. Thomas Humphreys, the genial and obliging Curator of the Edgbaston Gardens, on the excellent arrangements made for our comfort. In my opinion the most striking feature of the show was the exhibit of Mr. W. Welchman of Wisbech in the Bourne Cup Class. He staged a magnificent set of trumpets, some of a very high order of excellence, and I am beginning to look upon him as one of our greatest manufacturers of these most attractive flowers. His London exhibit a week previously was *fine*; so was his Birmingham one. The Commonwealth, Hereward and Lord Lister are flowers we would all like to possess. A second feature was the pink perianths. They are coming; there is no doubt of it. Mr. Buncombe and Mr. Wilson each had one at London. Mr. P. D. Williams and Mrs. Backhouse of Hereford each had them at Birmingham. One of this lady's was acquired by Messrs. Barr and Sons, and figured on their stand as Rosy Morn. It is a small, well-shaped flower (2½ inches by three-eighths of an inch), with a soft red eye and a decided warm, flesh-coloured perianth, shading off at the ends of the segments to a pale blush. The colouring is not so pronounced as in Mr. Buncombe's Red Wing. I hear, by the way, that this latter has changed hands under a guarantee of its coming the same next year. As it has flowered twice, I do not think the raiser need be afraid of any chameleon-like proclivities developing.

The third feature was the rising tide of seedlings, which every year now creates a new high-water mark record. The Midland schedule provides numerous classes for these new flowers, but they are none too many, and at no very distant date the number may have to be increased.

Lastly, a word to pat ourselves on the back on the way the schedule encourages "beginners." In Group C, that is, "open only to those who have never won more than three first prizes at any of the society's exhibitions," there were splendid entries and the competition was keen. Mr. Sydenham tells a tale of how the winning of a very low-down prize whetted his appetite in his early days of Carnation-growing, and so led him on to the position he afterwards attained. This Group C is based on the same principle, and I look upon Dr. Flower of Presteghn as one of its best advertise-

ments. I would like to have his fine red-cupped seedling (shown in Class 32) photographed with some such inscription as this underneath it: "See what encouragement in the early stages of a man's Daffodil life can do." I most heartily congratulate him on his first prize for three seedlings of his own raising.

On the second morning of the show I had a quiet look round and picked out some of the best novelties, which I am now going to describe. The award flowers were described in the report of the show published last week. Of these I will only refer to Norah Pearson, an illustration of which appears below, but which does not do it

page 220 last week, which were on Cartwright and Goodwin's stand almost before Mr. Engleheart had unpacked it. It may be described as a big Moonbeam, but with a much flatter cup, in the centre of which is a large deep green eye, just the colour of a young Lily of the Valley leaf, which happened to be near and with which I compared it. Size, 3¼ inches by 1 inch. Rmg Dove was a perfectly round Poet which figured in Mr. Crosfield's Cartwright Cup twelve, and also in his Herbert Chapman Poeticus Trophy lot. It is a most symmetrical flower, with deep red rim to its eye. Size, 2¾ inches by half an inch. It was a decided contrast to Sarchedon, which also was in the same collections.

A sport from Seagull was included in my own first-prize fifty in Class 1. It was found three years ago in a batch of my own Seagull which I had had for a long time, so I think it is an undoubted sport. In shape and size it is the counterpart of Seagull. It differs in the colouring of the cup, which is a sort of pinky buff with a thin, yellow edge. It attracted much attention.

Orb is a fine large red-eyed Barri after the type of Harold Finn. Size 3½ inches by seven-eighths of an inch. I know more than one visitor included it in the best three flowers in the show. It was staged by Mr. Crosfield in his Bourne Cup twelve. Ilex was another flower in this collection. It is a sort of pointed-perianth Challengier, with a very distinct rim of red to the cup. Size, 3¾ inches by seven-eighths of an inch. Hereward and The Commonwealth were two extremely good deep yellow trumpets in Mr. W. Welchman's Bourne Cup twelve. The first was described last week under my London notes, and I need only say here that a second look confirmed my high opinion of it as an exceedingly refined bloom. The Commonwealth was of quite a different shape and of a much deeper shade of yellow. It was distinguished by its rather short trumpet, which had a bold massive-looking edge. Size, 4¼ inches by 1½ inches by 1¾ inches. Lord Lister, in the same collection, deserves notice as a fine specimen of a pale bicolor Ajax. The three inner segments have a distinct curl.

In Advance Messrs. Pearson and Sons have a red-eyed Poet of great merit and novel colouring, inasmuch as there are two distinct shades of red in the very flat eye, the rim of which is of a deep dull shade and the centre more of an orange tone. Size, 2¾ inches by three-quarters of an inch. Discus (H. Backhouse, raiser) was bought by Mr. Bourne, and was, with the lovely Queen of Hearts, one of the features of his trade group. I called it a flat-eyed Leedsii, with a pale apricot and buff eye or shallow cup. There was much substance in the round-looking perianth, which was broad and overlapping.

There were three lovely bunches of Tinsel on Mr. Robert Sydenham's stand. It has an undulating, white, overlapping perianth, with a bright yellow

NARCISSUS NORAH PEARSON, A BEAUTIFUL NEW VARIETY SHOWN AT BIRMINGHAM BY MESSRS. J. R. PEARSON AND SONS.

justice. I call it my flower, as I think I may fairly claim to have discovered it. I do not think Mr. Duncan Pearson, when he left home to attend the show, had any more idea of putting it up for an award and bringing it back with a prize card round its neck than Pope Pius X. had of staying in Rome when he took his celebrated return ticket at Venice in order to attend the Papal conclave. Mr. Pearson thought a good deal of Lowdham Beauty perhaps, and also of the yellow-cupped Elfrida Pearson, but Norah was, comparatively speaking, only a Cinderella. The blooms that were more talked about than any others were two excellent examples of Emerald Eye, illustrated on

cup edged with orange. It is a charming flower. A sort of magnified Ethelbert will give readers an idea of what it is like. Although by no means a novelty, I must allude to the superb example of White Knight exhibited by Mr. A. M. Wilson in the single bloom class for white trumpets. To me it was the flower of all in the show. Its pure white, clean-cut perianth and elegant trumpet, with a slightly recurving rim, always must give it character as a unique florist's flower; but when good cultivation is added thereto, then we "have food for the gods." Ailsa is grand; so is Sybil Foster. Loveliness and Arian (all shown in the same single bloom class) are good, but "the best of all the five" was White Knight as shown by my friend Mr. Wilson.

JOSEPH JACOB.

PRIMULA COCKBURNIANA: HOW FAR IS IT PERENNIAL?

AMONG the many questions I have raised in THE GARDEN respecting the conduct of plants in cultivation, one has found that there has been a considerable diversity of experience. The experiences of many of your correspondents have helped, however, to solve some of the difficulties one has encountered, and have doubtless saved others as well as the writer much loss of plants and of time in experimenting with them. I have been much interested, for example, in the replies to my questions regarding *Anemone fulgens*, and I now venture to raise the question of the perennial or biennial habit of *Primula cockburniana* when in cultivation in this country, and that of the best place to grow it so as to secure its retention without annual sowing of seeds.

It is not everywhere perennial, and many have lost it from time to time after flowering. We find well-known authorities differing in their dicta regarding its duration. Mr. Reginald Farrer, for example, tells us that it is "quite perennial, like *P. capitata*, if carefully watched in a well-drained, cool place and frequently divided." This is from "The Rock Garden"; but in his "Alpines and Bog Plants" Mr. Farrer calls it "biennial." Of course, that erudite and fascinating writer is drawing upon his more recent experience in "The Rock Garden," but readers will require to note carefully the words "if frequently divided," which reservation, by the way, applies to so many *Primulas* if they are to be maintained in vigour. Mr. Lewis B. Meredith, whose cultural notes one has so much confidence in from experience of their general practical nature, says in "Rock Gardens" that *P. cockburniana* is "quite hardy, but, unfortunately, only a biennial." Other writers have had similarly conflicting views. Personally, I have been of opinion that *P. cockburniana* is practically a biennial with the majority of growers, and I have lost several plants in experimenting upon what I have thought likely lines, as well as upon those recommended by writers.

There seems no doubt as to its hardness, but the main question seems to be in the point of drainage. Like most of its kind from the same quarter, it bears the reputation of being a moisture-lover, and, in consequence, it is often treated to such conditions as will suit, say, *P. rosea*, with the result that it disappears from our ken in winter and never reappears after flowering. One is always inclined to attribute this to the exhaustion caused by seed production; but it seems quite likely that that is not the case, at least altogether, although we find that seedlings generally survive where adult plants fail.

I have been following up the subject, and, from one or two experiences which have more recently come under my observation, I am disposed to suggest that free drainage is the *sine qua non* with old plants of *P. cockburniana*, with the possible addition of frequent division, although I do not think the latter is absolutely necessary.

The best plant which has come under my observation, as having survived for three winters, after flowering for two summers and also bearing seeds, has been one in the gardens of Mr. W. A. Galbraith at Terregles, Dumfries, where the gardener, Mr. William Hutchinson, informs me it has been for three years and has flowered and seeded. This spring, after a trying winter, it is quite strong and vigorous. Mr. Hutchinson has favoured me with his treatment, and I think it will be found that the question of drainage is emphasised by his success. A bed of ashes about eighteen inches deep forms the base, and on this were laid about four inches of road grit, above this being placed about two inches of nice open loam. This would hardly seem ideal treatment for *P. cockburniana*, especially with an open, rather sunny position. Yet here the plant has behaved as I have previously indicated, and self-sown seedlings have been produced. I have observed in several other cases of successful retention of *P. cockburniana* that the drainage was unusually perfect, and I can well believe that a somewhat similar treatment to that adopted at Terregles may enable many to succeed with this bright scarlet plant we call Cockburn's Primrose. Personally, I am again experimenting with several plants, each being tried on a different method, and I hope to be able to report progress again. Yet I think the subject is so well worthy of consideration that I venture to express the hope that others will detail their practice in securing that *P. cockburniana* should remain a perennial in their gardens.

Dumfries.

S. ARNOLD.

THE SWEET PEA: AN APPRECIATION.

It is not arduous to understand the popularity of this flower, for there is no other annual that approaches it in floral profusion, in fragrance, or in exquisite grace. It is very unfortunate, however, that its odorous charm (which in the older forms was very pronounced) should, in the opinion of experts and amateurs alike, be gradually disappearing before the incessant popular demands for larger dimensions and crested formations, and the consequent results of excessive and exacting hybridisation.

It is perhaps somewhat consoling to remember that some of the available grandiflora varieties, such, for example, as Queen Alexandra, Dorothy Eckford and Helen Pierce, are still, for garden cultivation, among our very fairest and most effective flowers. Nevertheless, so great is the inconsistency of human nature, even when most seemingly conservative, that I am at the present moment getting my Parma-violet-coloured Eckfordian namesake crossed with a Spencer hybrid—merely for the sake of making it much larger and, therefore, more impressive—in far California by Mr. Lester Morse.

If all other annuals gradually disappeared from my garden, as many of them have done, and only the Sweet Pea and Climbing *Nasturtium* remained, I would be quite satisfied with my floral possessions of an aspiring description; for along the half-shaded borders, with an environment everywhere of Roses

(of which I have 120 distinct varieties) and Oriental and Occidental Lilies, the Sweet Pea blossoms everywhere, and "nothing can stale its minute variety." There is no other flower, with the exception of the Rose, that so tenderly links the pensive present with the fadeless past. By the hybridising genius of the late Mr. Henry Eckford and his numerous successors in Europe and America it has developed capabilities undreamed of by our ancestors, and though it has, as I have indicated, somewhat deteriorated in the essential attribute of fragrance, it is unquestionably more commanding in its beauty than it ever has been before. Its colouring has been, especially, intensified in a marvellous degree.

Every earnest cultivator of the Sweet Pea has, I presume, his own special favourites, and among mine are Etta Dyke and Nora Unwin, Dobbie's Scarlet and Vermilion Brilliant, Earl Spencer, Melba, introduced by Messrs. Dobbie and Co., and raised by Mr. Malcolm of Duns; Rosabelle, usually regarded by experts as a greatly-improved Margaret Willis; May Campbell, which greatly resembles in colour a favourite *Nasturtium*; Marie Corelli, Eltrida Pearson, Evelyn Homus, Paradise Ivory, Mrs. C. W. Broadmore, John Ingman, Elsie Herbert, Mrs. Hugh Dickson, Thomas Stevenson, Cleinart, Gustave Hamel, Nubian, Mrs. Rontzahn Spencer, Dorothy Eckford, Florence Nightingale, Helen Pierce and Asta Ohm.

Ford Rosebery has asserted that to him the Sweet Pea is more fascinating than the Orchid. Its beauty and fragrance can at least be more intensely appreciated under widely different atmospheric conditions. DAVID R. WILLIAMSON.

TREES AND SHRUBS.

THE HARDY BROOMS.

ALTHOUGH the name of Broom is more closely associated with *Cytisus scoparius*, the common Broom of our commons and hillsides, than with other species, it has been pretty generally adopted for all the kinds of *Cytisus* and *Genista*, and the Brooms are looked upon as a very important group of late spring and early summer flowering shrubs. That they are popular is not to be wondered at, when it is considered that they are easily raised, quickly attain flowering size, flower freely every year and give comparatively little trouble.

Propagation.—This may be effected in any one of three ways. Those kinds which come true from seeds—are best said to refer to all the species—are best raised from seeds. But there are certain hybrids and varieties which have to be raised in other ways, and in such cases cuttings or grafts are used. As a rule, cuttings 3 inches to 4 inches long are made from young shoots, with a slight heel of old wood, during July or August, and are inserted in sandy soil in a close but cold frame, artificial heat being detrimental. After being firmly inserted they are well watered and kept close and shaded from sun for several months, giving water when necessary. Growth commences with the lengthening days in spring, when air is admitted, the rooted cuttings being removed in April. When grafting is resorted to, the work is usually performed indoors in spring. As a rule, the common *Laburnum* is selected as the stock, and either young plants or sections of root are used. The scions may be made of either one year or two year old wood, but in either case it must

be woody, that which is of a pithy character being unsatisfactory. The side graft will answer in many cases, but it is often necessary to use a wedge graft on account of the difference in size between stock and scion. When grafted, the plants are placed in a warm and close frame until the union is effected, when they are gradually hardened off and removed to the open air. Kinds like *andreamus* and *præcox* are increased by cuttings or grafts.

Pruning.—During the first two or three years it is necessary to keep the plants well pruned, otherwise they will grow rapidly in height and become bare at the bottom. By repeatedly cutting the young shoots back, a good foundation is laid, and pruning in later life is reduced to a little shortening of the growths after flowering. Brooms as a whole object to being pruned into old wood, and a plant which is cut back into wood which is three or four years old never breaks freely. The purple-flowered Broom, *Cytisus purpureus*, differs from other kinds by requiring to have the old shoots cut clean away each year, for it renews itself annually by young growths, which spring from the rootstock. Another kind, *Cytisus nigricans*, and a Gemsta, *G. elatior*, also require different treatment, for they flower during late summer from the current year's wood; therefore they must be pruned during winter or early spring.

Planting.—A few words are necessary regarding planting, for although the Brooms thrive in almost any soil of a loamy character, from sand and gravel to fairly stiff clay, they must be placed in permanent places while quite small, for it is almost impossible to transplant well-grown examples with any degree of success. As a rule, the root system is ridiculously small in comparison to the branch system; therefore large plants fail to obtain their proper supply of food when the roots are disturbed.

The Best Kinds.—*Cytisus scoparius*, the common Broom, naturally suggests itself as one of the most useful, for it grows in the poorest soil and creates a glorious effect when covered with its golden flowers, whether growing on poor ballast on railway banks, in stony ground on moors and commons, on mountainsides, or in gardens. Its variety *andreamus*, which is recognised by the two brown petals borne by each flower, is a great favourite; while the Moonlight Broom, a variety with cream-coloured flowers, is also very attractive. The white-flowered Portuguese Broom is also a popular plant, its small white flowers appearing with the greatest freedom during May. *C. Dallmorei* is a hybrid between the last named and *C. andreamus*, growing as tall as either, it is intermediate in character between the two, but it has showy purplish blossoms and is quite distinct from any other Broom. Another hybrid is noticed in the early-flowering *C. præcox*, which grows 5 feet to 6 feet high and flowers magnificently. Its only drawback is that its cream-coloured flowers have

a disagreeable odour. *C. purgans* is a dwarfier plant than those previously mentioned. Growing about three feet high, it is of upright habit and produces golden flowers. The Eastern European *C. biflorus* is one of the earliest kinds to flower, and is often opening its blossoms in April. It grows from 2 feet to 3 feet high, and usually bears its flowers in pairs from axillary buds. *C. capitatus* differs from other kinds by producing its yellow flowers in rather dense heads from the points of the branches. *C. purpureus* is a charming kind which is very different in appearance from the other Brooms. Of dwarf habit, it scarcely attains a height of 1½ feet, forming slender, arching branches which bear a profusion of pretty, purplish flowers. A close relation of the last named is found in the

THE PREMIER GREEN-EDGED AURICULA, WM SMITH, SHOWN BY MR. J. DOUGLAS AT THE LONDON SHOW LAST WEEK.

hybrid *C. versicolor*, which also has purplish flowers. *C. Ardoin* introduces quite another group, for it is a very dwarf grower, suitable for the rockery. Its flowers are golden. Several natural hybrids have been obtained from it, two of the best being the golden-flowered *Beau*, and *kewensis*, which has cream-coloured flowers. Other dwarf Brooms of considerable beauty are *C. decumbens*, *C. leucanthus*, *Gemsta pibosa*, *G. sagittalis* and *G. dalmatica*. The Spanish Gorse, *Gemsta hispanica*, is another excellent plant. Growing about two feet high, it forms excellent cushion-like plants, which towards the end of May are globes of gold. *G. emerea*, *G. virgata* and *G. athenensis* are tall-growing kinds. D.

COLOURED PLATE.

PLATE 1471

THREE GOOD PERPETUAL-FLOWERING CARNATIONS.

DURING the last decade the Perpetual or winter flowering Carnations have undergone a truly wonderful change, and one that has made for all-round improvement. At the time when these Carnations first began to attract general attention in this country, there were not a large number of varieties, and these were mostly of American origin. Weak, attenuated stems and thin, colourless flowers, with none too robust constitution, characterised the Perpetual-flowering Carnations of those days; but, thanks to the efforts of raisers in this and other countries, all these defects have been remedied. A few years ago, when Britannia was attracting a good deal of attention, we must confess that we feared that precious attribute, fragrance, was in danger of being "improved" out of existence, if we may use such a phrase; but after a few rather more than gentle warnings, raisers saw the folly of their ways, and have, during the last three or four years, given fragrance its rightful place.

The three varieties shown in the accompanying coloured plate were raised by Messrs. Allwood Brothers at their Wivelsfield nurseries, Hayward's Heath, to whom we are indebted for the flowers from which the coloured plate was prepared. All three are excellent varieties, but perhaps *Mary Allwood* is the doyen of the trio. It has gained 92 points out of a possible 100 from the floral committee of the Perpetual Flowering Carnation Society, the highest number yet awarded from that source to any variety. It is good in shape, fragrant and particularly free-flowering. Need we say more? *Wivelsfield Wonder*, the striped flower, will probably not appeal to everyone, but we must confess to a partiality for it. The flowers are well poised on long, stout stems, and are really first-class for decorative purposes. But its delicious fragrance appeals to us more than that of any other variety we know. We must have *Wivelsfield Wonder*, if only for its scent. It is a seedling from the famous old variety *Mrs. Bradt*, which was, we believe, one of the parents of *Enchantress*, and which has played an important part in the genealogy of most of our best Perpetual-flowering Carnations.

Wivelsfield White is a white seedling variety that is as yet in its infancy. We have seen and admired it on a number of occasions, and we believe that those salesmen in Covent Garden Market who have seen it think very highly of this variety for decorative purposes. It is a pure, glistening white; the flowers are very full, deliciously fragrant and, we believe, more productive than any other white variety. If it lives up to its present reputation, this Carnation should have a particularly brilliant future in store.

THE GREENHOUSE.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

THE Chrysanthemum grower and enthusiast has much to do during the month of May, as the plants, no matter in what stage they are in, should be growing freely, and the best advice I can give just now is to allow the plants all the light and air possible if still in the frame, with perhaps this exception—the late-rooted plants that are intended for growing in small pots. These probably have hardly got over their first potting, and must be very carefully coaxed along for a little while; and though they may have the benefit of the lights over them during the day to prevent them flagging too much, their removal in the afternoon and evening will do much to help the plants to attain that hardness that is necessary for them to stand (without flagging) the full sunlight. Early in the month, certainly during the second week, all established plants, whether for large flowers or decorative purposes, should be removed to the open air, giving each sufficient space to develop its leaves properly. A somewhat sheltered, though open position is the best for the plants, and some provision should be made to spread tiffany over them in the event of late frosts occurring. It may also be advisable, in the event of strong winds, to run a length of tiffany on the windward side of them, for it must be borne in mind that the foliage for the first few days after their removal from the frame is very brittle, and strong winds, if not broken somewhat, do a great deal of damage.

Staking is also necessary, and I make a practice of putting a 2-foot or 3-foot stake to each plant (according to the varieties) as they are stood out; this carries them nicely till they are potted and placed in their position for the summer.

Green Fly at this season is sometimes troublesome, but a weekly run through the plants with the Tobacco duster will keep this pest in check. I am apt to think this is preferable to, and quite as effective as, spraying the plants with an insecticide, as the slightest overdose will burn the young growing points, and any injury to the foliage now, either by fly or insecticide, will spoil the look of the plants for the whole season.

Stopping.—There are a few of the exhibition varieties that, if left to break naturally, would produce their blooms somewhat late. Such varieties should be stopped at once, and these include the whole of the Jameson family, Fred Green, Fred Chandler, Miss Boyes, Bob Pulling, Mrs. H. J. Jones, Mrs. W. T. Smith, Mrs. R. C. Pulling, Miss May Fox, J. Surry, Mrs. A. L. Usher, Joan Stratton, Miss Rodwell, C. J. Bien, W. H. Head, Mrs. Henshaw and Mrs. H. D. Thornton. Towards the end of the month the following varieties, if they have not already made a natural break

should have their points pinched out: Hon. Mrs. Lopes, Captain Mtford, Colonel Converse, Queen Mary, Mrs. Gilbert Drabble, Frances Rowe, Miss A. E. Roope, Lady Frances Ryder, Frank Payne, Master Rex, M. Paolo Radaelli and Mme. G. Rivol.

Potting.—About the third week in the month some of the earliest-rooted exhibition varieties should be in a forward enough condition to warrant them being given their final shift. Needless to say, a well-prepared compost should be employed, not necessarily rich in manure, but of a good holding nature that the plants will make plenty of roots in. Firm potting is essential, and well-drained pots ensure them going through the season without becoming water-logged. Plenty of space should be left at the top of the pots to allow of two or three surface-dressings later in the season. After potting, the plants make root more quickly if stood closely together for a time, and if the weather is warm and dry, frequent syringings overhead will help them to get over the shift quickly. Watering

that can be obtained if they are well looked after. Plant firmly and stake at once, making the soil quite fine round the plants, so that there is no harbour for slugs. If the weather is very dry, give one good watering, after which in a normal season very little water will be required till bloom buds appear, when they may be assisted with a little natural or artificial manure.

Stovey.

THOMAS STEVENSON.

ROCK AND WATER GARDEN.

A RARE AND BEAUTIFUL PRIMROSE.

(PRIMULA REIDII.)

ALTHOUGH this Himalayan Primula has been known for a considerable number of years, it is still an uncommon plant in our gardens. This is perhaps due in some measure to its requirements under cultivation in our changeable climate

PRIMULA REIDII, A RARE AND BEAUTIFUL PRIMROSE WITH WHITE FLOWERS.

in must not be delayed too long, or the ball of soil will become very dry, when several waterings will be needed to soak it thoroughly through again. March or April struck plants, as soon as nicely rooted in the 3-inch pots, should be potted on into 4-inch or 4½-inch pots, keeping the lights on them for a few days till they become established, when they should be removed to the open air and treated in the same way as the earlier-rooted plants.

Early-Flowering Chrysanthemums.—Whether intended as cut flowers or for the embellishment of the garden, these should be planted out during the early part of the month. Richly-manured soil is not necessary, but ground that has been well worked is quite essential for success. For cutting purposes the plants should be arranged in beds of three or four rows wide, and if planted in this manner they may easily be covered in the autumn. It is astonishing the quality of bloom

conditions being imperfectly understood. To those possessing a cool greenhouse or frame, little difficulty should be experienced in growing this species well.

It is most satisfactory to raise this plant from seed. This should be sown during February or March in a seed-pan and kept under moist conditions in a temperature of from 50° to 55°, watering when necessary by standing the seed-pan in a saucer of water. Germination soon takes place, but the young seedlings should be left until the first true leaves are formed. They may then be pricked out carefully in a fine compost such as is generally used for this purpose, keeping them under the same conditions of temperature and moisture as that used for germination, taking care to shade from the strong sunlight until they are established. Treated in this manner the plants produce a strong autumn growth, and sturdy specimens are obtained

before winter. About October they may be placed in a cold frame and kept fairly dry at the roots until March, when they may be removed to warmer quarters if required early and given a more liberal supply of water, and the greater percentage will be found to produce their attractive white flowers with the growth of the leaves. If tried upon the rockery, every means possible should be used to retard growth until this is safe from late frosts, and a sheet of glass or some such covering used to throw off excessive moisture. This species is really perennial, and may be propagated by dividing the young shoots that sometimes spring from the sides of the plant; but raising by seed is preferable, and gives better results. The illustration shows one of the two pans exhibited at the Primula Conference held at the Royal Horticultural Society's Hall on April 16, and portrays the beauty of this species when well grown.

R. L. HARROW.

Royal Botanic Gardens, Edinburgh.

PLANTS FOR A STREAM GARDEN.

Not every garden can boast natural means wherein to cultivate water-side plants, and

actual water-level, for although numerous plants revel with their roots in wet soil, yet they enjoy somewhat drier conditions around the crowns.

On heavy soils, and without large trees in the vicinity to send their roots into it, well-puddled clay offers a cheap and inexpensive material for holding water. It requires to be thoroughly worked into a plastic condition before laying down, and, to ensure the work being thoroughly done, only a small quantity should be treated at a time, while all completed parts must be kept damp until water is turned on. A thickness of 6 inches to 9 inches is generally employed. Cement concrete is also much in request for lining water areas, and is best laid down in two coats; but before doing so all moved ground must be rammed absolutely firm, otherwise shrinkage will inevitably follow, and may possibly ruin the work. The first layer is formed of rough ballast and cement, used in the proportion of three of the former to one of the latter, and is well beaten together while it is green. The second coat is applied when this is partly firm but not fully set, so that both may

and reliable. *Mimulus Brilliant* spreads out into great masses of coppery red flowers. *Primulas rosea*, *japonica*, *pulverulenta*, *cockburniana*, *Sieboldii*, *sikkimensis* and *bulleyana* are invaluable for this position, and present a bright display from April till the end of July. *Ranunculus acrifolius plena* and *acris flore plena* are bright subjects for an early display. *Trollius in lemon*, yellow and orange follow later. Dwarf *Astilbes* like *Silver Sheaf*, *chinensis* and *Queen Alexandra* are conspicuous objects in the water garden, where the moist conditions bring out all their latent beauty.

Of the Iris family, all the selected forms of *Iris sibirica* are good; so, too, are the hybrid forms of *Monspur* and the giants *Iris aurea* and *gigantea*; both flower in July. *I. Kampferi* presents most gorgeous colours and the greatest variety, and therefore calls for liberal representation. *Rodgersias podophylla*, *pinnata* and *tabularis* are reliable bog plants of moderate growth. Any of the *Arendsii* hybrid *Astilbes* give an effective display, and the species *Davidii*, *grandis* and *rivularis* develop masses of their showy spikes.

This also applies to *Spiræa*, of which *palmata* and *venusta* are excellent among the dwarfier kinds, and *kamschatica* (*gigantea*) and *Arunca* the best of the tall growers. *Senecios*, being strong subjects, demand much space. *Artemisia lactiflora* flowers late, and on this account is welcome. Varieties of *Phlox decussata*, *Michaelmas Daisies* and *Solidagos* are never finer than when informally grouped under the conditions of a bog.

The light and graceful habit of ornamental Grasses, when suitably placed, augment the beauty of the flowering plants. In this connection the elegance of Bamboos must not be overlooked, as they are imitable as backgrounds in small gardens, and in larger areas they may figure prominently in the foreground close above the water's edge. Other effective

I.—A WELL-TRAINED PEAR TREE IN THE ROYAL GARDENS, WINDSOR.

elaborate facilities are a luxury for the few. Happily, the pleasure associated with water gardening may be enjoyed with the aid of quite simple means on a small scale, and the success obtained with the latter is often very great. A pretty effect is given to the water garden when arranged in the form of a stream garden, the water being given an irregular course and for the greater part of its length confined to a narrow channel, with one or more wider parts introduced in the form of pools, in which *Nymphaeas* and other choice aquatics can be grown. While the narrow channel and pools will form the actual area showing water and be lined with some impervious material, the sides of these, if shelved some nine inches below ground-level and lined with similar material and filled with soil, will make congenial positions for growing moisture-loving and bog plants. The soil in these beds should come quite 9 inches above

minute together. Fine washed sand three parts and Portland cement one part, well mixed and laid over a 3-inch coat of the rough material, will generally prove sufficiently strong for any water scheme on a moderate scale, and if the face is well worked as this coat is laid, a perfectly impervious lining will result. When all is thoroughly firm and hard, the bog-beds are filled with a compost of two parts fibrous loam to one part of peat and leaf-soil mixed, and if this is made moderately firm, planting may take place at once.

April and May are the two best months of the year for moving water and bog plants, as growth is then becoming active, and with all the summer in front of them they become established and often give a good display the first year. Of effective bog plants that succeed close to the margin of the water, *Caltha palustris flore plena* is showy

and reliable. *Arundo macrophylla glauca*, *Cyperus longus*, *Scirpus zebrinus*, *Glyceria spectabilis variegata*, *Carex pendula* and *riparia variegata*, and *Miscanthus zebrinus*. Some of these are aggressive in character, and all are best given positions where they cannot overrun choicer things. Small ledges at the sides of the basins or a few loose stones along the margin placed in the water, with a quantity of soil to start them, is the best way I have found to attain this end. In the drier part of the bog *Lilium pardalium* and *superbum*, with *Cyrtopodium spectabile* and some *Osmundas*, *Onoclea* and *Struthiopteris* among them, will present a charming feature, to which *Trilliums* and *Dodecatheons* may be added as a ground carpet. There are, of course, many other good and suitable plants, but the above will suffice for a start.

THOMAS SMITH.

Coombe Court Gardens, Kingston Hill, Surrey

TRAINED FRUIT TREES AT FLOWERING TIME.

WHEN fruit trees are in flower it is an anxious time for the fruit-grower. An abundance of blossom may be a hopeful sign; but, alas, how often a good promise has been followed by a paucity of fruit! The havoc that may be wrought through frost in a single night is only too well known. Judging by recent observations, however, the Apple-sucker, or Psylla, is responsible for much injury to Apple blossom, while a great deal of damage usually attributed to frost is due to a bacillus, so far imperfectly understood, which causes the flowers to blacken and fall off. So far as the Apple-sucker, or Psylla, is concerned, we refer readers to THE GARDEN for March 8, containing the life-history of the pest, together with numerous illustrations. The Apple-sucker is a tiny creature which attacks the flowers as they begin to expand, and the dead flower-trusses will hang on the spurs for a long time. This pest has been kept in check by spraying with a mixture of quicklime and salt when the trees are dormant, followed by a decoction of Tobacco at the time of the bursting of the buds. Green fly and the caterpillars of both the winter moth and the Codlin moth are likely to prove troublesome, but these may be kept in check by spraying with a solution of arsenate of lead (2lb. to fifty gallons of water) soon after the petals fall. Arsenate of lead has been found of greater value than Paris green, and the latter is being discarded in favour of the former by many of our large fruit-growers.

At one time fruit trees were trained with greater care than they are to-day. Gardeners of the old school took the keenest pride in this work; but now it is only in well-ordered gardens that one finds trees trained in the same skilful manner as they were a few decades ago. In a great measure this is due to nurserymen, who are anxious to make saleable trees in too short a space

of time, whereby the foundation of the trees is seriously impaired.

The three accompanying illustrations depict well-trained fruit trees in the Royal Gardens, Windsor. In each case it will be noted the tree is full of fruiting wood, and the trusses of bloom are seen from the base to the top of each trained branch. This point is well portrayed in illustration No. 2, showing a shapely tree of Pear Winter Nells in full bloom. Here there is as much bloom in the centre of the tree near to the main stem as there is on any other part of the tree. Now, it is only trees well trained in early life that give such satisfactory results.

Trained trees require constant care and attention at all times, and at the present season there is much to attend to. Should a leading shoot be making luxuriant growth at the expense of another, it is advisable to slightly bend it down, for this will have the effect of checking the growth. If, on the other hand, a shoot is weak, it may be trained

2. - PEAR WINTER NELLS WITH A FINE SHOW OF BLOOM.

up for the time being, and, having made satisfactory growth, it may be brought to its correct position. Young growths, particularly on Peaches and Nectarines, require thinning and regulating, the remaining growths being tied and nailed up in position. Very shortly the thinning of stone fruits may be carried out, so as to secure an even distribution. In doing this it is advisable to first of all remove imperfect and badly-placed fruits, but it is not wise to hasten the work of thinning until one is sure of the fruits that are set. With trained Pear trees it is customary in some gardens to wash them well down with a hose or garden engine when the fruits are set, and the practice has much to commend it, for it is a good method of removing imperfectly-set fruits.

Fig. 1 on the page opposite depicts a remarkably well-trained tree furnished throughout with fruiting spurs. The wire trellis over which fruit trees are trained (see fig. 3), is one of the features of the famous Windsor gardens. A low trellis, clothed mainly with Pears, runs either side of the central walk in the kitchen garden. It is a feature that might well be adopted in other gardens. In regard to wall-trained trees, it is well to bear in mind that the walls keep off a great deal of water, and the trees are often dry at the roots, even after heavy rains.

3. - THE METHOD OF TRAINING A FRUIT TREE OVER A WIRE TRELLIS.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Early-Flowering Chrysanthemums.—No time should now be lost in getting these planted, whether they are intended for beautifying the garden or for cut flowers. It is not necessary to plant in richly-manured ground, but there should be sufficient nourishment in the soil to maintain a steady growth throughout the summer, giving a little further nourishment just prior to the flowering period.

Planting in Borders.—The plants make a good display in the borders when planted in fairly large clumps of from three to ten plants; but such large clumps can only be utilised when the borders are wide, and consideration should be given in selecting the colours to harmonise or contrast with the other occupants. For cutting purposes they should be planted in beds about six feet wide, where they can be easily looked after during the summer and covered, if necessary, during the blooming period, allowing from 18 inches to 2 feet between the plants, according to the variety.

Summer-Bedding Plants.—Should the weather be favourable, some of the more hardy plants, such as Ivy-leaved Pelargoniums, Marguerites, or even Zonal Pelargoniums, properly hardened, may be removed from the frames to a sheltered position out of doors, though it may be necessary to have light tiffany at hand in case of late frosts. This gradual hardening off will make room for the more tender occupants of the houses and frames, many of which it may be unsafe to remove to the open air till the end of the month. Zonal Pelargoniums and Fuchsias that have filled their pots with roots should not be neglected in the matter of manure, and, when handling, a pinch of Clay's Fertilizer should be given to each of them, thus keeping them in good condition till planting-time.

Plants Under Glass.

Roses.—Climbing Roses in pots should be well looked after in the way of water and manure. Precautions must also be taken to keep them free from fly by fumigation or spraying. At this season full sunlight is not necessary, and a little shading should be given to keep the temperature down and to prevent loss of colour in the blooms.

Hybrid Perpetuals and Hybrid Teas from which the blooms have been cut may safely be removed to the open air. Many of the plants will, no doubt, have made a fair quantity of secondary growth, and if the plants are carefully looked after, this will provide a certain amount of bloom before the outdoor Roses come on to flower.

Gloxinias coming into flower should be afforded a slightly lower temperature than when growing, also a less moist house would be advantageous. Seedling plants must be kept growing and potted on as they require it, though 4½-inch pots should be large enough to flower them in the first season.

Tuberous Begonias started early in March should now be fit for transferring to their flowering pots, a rich, open compost made fairly firm in the pots suiting them well. A certain amount of humidity in the atmosphere of the house and a little shade are two points that must be observed to attain good results with these plants.

The Kitchen Garden.

Peas.—Many of the midseason Peas will now be fit for staking, and in the event of a wet season the height of the stakes should not be stinted. Slope the top of the stakes slightly outwards, thus avoiding the trouble of the haulm growing through and hanging down, which is often the case when the tops of the stakes meet.

Late Peas.—In some soils it is advisable to sow late Peas on the top of well-prepared trenches, the extra manure and deep working tending to tide them over a very dry spell. In this district Autocrat is by far the best late Pea, and, being very robust in habit, the plants should be thinned to about four inches apart when about two inches high.

Broad Beans planted out of pots are sometimes apt to be blown or topple over when the pods commence to swell, so it is advisable to stake or run a string from end to end of the rows to keep the plants upright. The early batch should be topped as soon as sufficient pods are set to form a crop, and a dressing of artificial manure will greatly help them in this stage.

Seedling Onions, Carrots, Beet, Turnips and Brassicas should be systematically sooted to ward off slugs and attacks of fly, and as soon as they are nicely through the soil the hoe should be run between them, repeating this operation as often as may be necessary to keep the soil from becoming beaten down or clogged, as in this condition seedlings are very slow in making growth.

Fruits Under Glass.

Thinning Grapes.—The matter of thinning in successional houses must be proceeded with, as a few days' neglect may mean that the berries will become tight, and the thinning operation is much more difficult and the berries likely to be injured by thrusting the scissors between them.

Midseason and Late Grapes naturally need rather more thinning than the earlier varieties, and round-berried varieties more than oval ones. Acanthes and any other varieties with heavy shoulders should be carefully tied up before thinning, and I would again remind readers that then the berries on the shoulders may be left rather more closely than the rest of the bunch, so that as the berries swell they are just thick enough to keep the top berries in position, and so improve not only the shape but the weight of the bunch.

Tomatoes.—Early batches are fast swelling their fruit, and if the plants happen to be in 9-inch pots, the point of the shoot should be pinched out after they have set about five good trusses, this being quite sufficient for a pot of this size, unless the roots can get into the soil or turves which may be placed beneath the pots. Such a stopping naturally increases the weight of the trusses as well as inducing early ripening, which is very essential for the earliest crops.

Successional Batches must be got into their fruiting quarters as they become fit. If planted in borders in the houses, too great a root-run is not necessary, as it often induces too free growth. A few inches of soil, with top-dressings as the plants make growth, is the best system to adopt. Keep the plants fairly dry till the first trusses of bloom begin to open, when they may have rather more liberal treatment.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Calceolarias.—If the weather is good and the ground clear, Calceolarias may now be planted with safety, although it might be well to delay dealing with *C. amplexicaulis* for ten days or so.

East Lothian Stocks.—These showy annuals may now be planted out if the weather is favourable. See that the ground has a good tilth and hit the plants carefully with a trowel, with which they should be planted in preference to a dibber. Having few fibrous roots, Stocks should be watered immediately after being planted. It is a good plan to push a twig of Yew or Thuya up the spout of the watering-pot to break the force of the flow, and then water without a rose.

Sowing Biennials.—Some people prefer to sow Wallflowers and other biennials in June; but if one desires to have strong plants either for autumn or spring planting, I would recommend sowing at the present time. Among Wallflowers, Vulcan for a red and Golden Monarch for a yellow are unexcelled, while Eastern Queen, Ruby Gem and Primrose Dame are excellent in their way. Among Forget-me-nots, Royal Blue and Myosotis alpestris Victoria are hard to beat. In selecting Sweet Williams for massing, selfs are the best. Sutton's Pink Beauty and Sutton's Scarlet, with a good crimson, will satisfy most tastes. Other biennials to be recommended are Canterbury Bells, Carnation Grenadin, and *Achusa italica* Dropmore variety and Opal. It is too early to sow Hollyhocks yet.

The Reserve Garden.

Preparatory Work.—See that the ground is in a fit condition for the reception of the various subjects to be planted during the next few weeks. Where Primulas and Polyanthus are to be planted for the summer, a fair amount of humus will be necessary, either in the form of well-rotted manure or half-decayed leaves.

Planting Bulbs.—Good varieties of Narcissus and Tulip that have done duty as spring bedders should be run into nursery lines rather thickly, to be lifted and dried for future use when the foliage has died down.

The Rock Garden.

Half-Hardy Plants.—The bulk of our *bona-fide* alpine plants bloom in spring or early summer, leaving the rock garden rather grey and uninteresting during the late summer and autumn months. This can be remedied if a pocket here and there is left vacant for suitable summer-flowering subjects, and these may either be annuals or half-hardy perennials. Among suitable annuals I would suggest the following: *Abronia umbellata*, *Acroclimium*, *Alyssum minimum*, *Limnanthes Douglasii*, *Linaria* in variety, *Matthiola bicornis*, *Nemesia* in variety and many others. Among perennials might be mentioned *Cupheas*, *Fuchsia procumbens*, *Alternantheras*, *Echeverias* in variety and *Lobelias*.

Plants Under Glass.

Zonal Pelargoniums.—Spring-struck stock for autumn flowering should now be removed to a cold frame and be gradually hardened off. Older plants for summer display should be pinched for the last time.

Seedling Francoas.—Where a batch is being raised from seed, the plants will now be ready for potting up into 3-inch pots, after which they should be removed to a cold frame.

Rehmannia angulata Pink Beauty.—This useful conservatory plant will now require staking, for although severely pinched, as it ought to be, it grows fairly tall. Only slender stakes, such as Bamboo tips, should, however, be used to support its slender stems.

Fruits Under Glass.

Stopping Vines.—This work must have close attention, both for the conservation of energy and the admission of sufficient light. Sublaterals should not be allowed to develop beyond one joint.

Aerial Roots of Vines.—These may be induced from various causes—too hard forcing, excess of moisture, or insufficient ventilation. Their appearance should be a warning to revise the general régime. Where the foliage is being maintained in a leathery condition, aerial roots will not give much trouble.

Melons.—Plants swelling their fruits should have abundance of water at the roots, with occasional doses of liquid manure. A mulching of old Mushroom manure will prove highly beneficial. Attend closely to pollination where required.

The Hardy Fruit Garden.

Loganberries.—Attention must be given to tying in the young shoots at an early stage, as they are easily damaged. The same remark applies to Raspberries, especially where they are trained to a trellis.

Hoeing.—The Dutch hoe should be kept going freely, for by doing so one aerates the soil and keeps down weeds by one effort.

The Vegetable Garden.

Broccoli.—It will be a great advantage if the young plants are pricked out about three inches apart, instead of leaving them in the seed-bed to become drawn and weakly. As soon as the present season's crop is cut, the ground should be cleared, manured and dug finely to be ready for a summer crop. Leeks or late Peas form a good succession to Broccoli.

Earthing-Up Potatoes.—Prior to commencing this operation the ground should be forked over between the drills, as the Potato enjoys a free root-run. Earthing-up should be done twice, drawing up a little earth when the stems are about six inches high, and completing the operation a fortnight later.

Broad Beans.—These should be earthed-up when about a foot high. It is sometimes asked, "What is the utility of this earthing-up?" and I reply, "It steadies the plants and raises the temperature of the soil." A late planting may yet be put in, but no time must be lost.

Thinning Turnips.—Early crops should be thinned out first to about two inches apart, every alternate plant to be thinned out a fortnight later. When pulling commences, thin out again to allow the remainder to swell out.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mans, Midlothian.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Primula La Lorraine.—A hybrid said to have originated from the crossing of *P. Veitchii* and *P. cortusoides* anona, the new-comer being intermediate between the parents. *P. Veitchii*, itself of the *cortusoides* set, appears in the hybrid to have influenced leaf-growth and wooliness with compactness of flowering, the other parent having given of its colour and size of blossom individually. The flowers are rose-coloured, almost *Rose du Barri* shade. Only a small plant was exhibited, and though remarkable for freedom of flowering, will doubtless presently reveal a fuller development. It is of Continental origin. Shown by Mr. M. Prichard, Christchurch, Hants.

Æthionema armenum Warley Hybrid.—In effect this pretty alpine sub-shrub is that of a rosy red flowered, compact-growing *cordifolium* (*Heris jucunda*) rather than that of the species to which it is here referred. In any case, it is a delightful plant of about six inches high, the flowers arranged in close, terminal, rounded racemes. From Miss Willmott, Warley Place.

Rose Erna Teschendorff.—A crimson-flowered *Polyantha* Rose after the style of *Jessie*, but of a deeper crimson than that variety. Great things are said of it, though British gardeners at least would have preferred a more easily pronounceable name. This pretty Rose has repeatedly been shown this year by Mr. George Prince, Longworth. It was presented on this occasion by Mr. Profitlich, Twickenham.

Wallflower Primrose Monarch.—This has pale-yellow flowers of large size. The habit is dwarf and compact. Unfortunately, the true Wallflower fragrance is quite lacking in the plant. From Mr. Moss, Kelvedon, Essex.

Narcissus Venetia.—A delightful triandrus hybrid of singular purity and grace. Many of the scapes were two-flowered, the new-comer showing a plant of considerable vigour. Individually the flowers were about three and a-half inches across. From Mr. W. B. Cranfield, Enfield.

Narcissus Evangeline.—A *Leedsii* variety which has come in for honours rather late in the day. Notwithstanding, it is a good and desirable sort, holding its own in any collection, and cheap withal. It is a somewhat rounded, shapely flower, 3 inches across, and of ivory white colour. From Mr. H. N. Phillips, Olton.

All the above were shown before the floral committee of the Royal Horticultural Society on the 29th ult., when the awards were made.

THE EDITOR'S TABLE.

Star-Flowered Cinerarias.—From Messrs. Jarman and Co., seed-growers and nurserymen of Chard, Somersetshire, we have received a great variety of the Star-flowered Cinerarias. The flowers have quilled and in some cases curiously twisted ray florets, and are popularly known as Cactus Cinerarias. A very fine range of colour, including clear blues and soft pinks, was included, and Messrs. Jarman, who grow the plants extensively for seed, inform us that the strain is perfectly fixed. For greenhouse and conservatory decoration in early spring this race of Cineraria stellata is sure to be widely grown when better known

THE FRUIT GARDEN.

SEASONABLE NOTES ON FRUIT.

Caterpillars on Gooseberries.—It is of paramount importance that amateurs shall maintain the keenest watch on their Gooseberries, or the probabilities are that they will wake up to find the plants so terribly infested with caterpillars that the most drastic steps will have to be taken to ensure their complete extirpation. These enemies are rapid and industrious workers, and while it is acknowledged that the Gooseberry is an accommodating plant, with remarkable powers of recuperation, it is impossible for it to sustain such an attack without serious debilitation. Therefore watch, and the instant an enemy is seen destroy it. There are preparations advertised in THE GARDEN that will most admirably answer the purpose for which they are advised, or reliance may be placed on lime or white Hellebore powder dressed on when the leaves and stems are damp after rain or dew. Repeated applications will be required to keep everything in order.

Weak Trees.—Fruit trees that are not making as much progress as one could desire ought to be given special assistance. The trouble with those who are not experienced in fruit culture is, as a rule, to check them in their desire to feed, with a view to producing a tree that is conspicuous for its handsomeness; but, unfortunately, such a condition spells unfruitfulness in many instances, and the grower is therefore going on the wrong track. Where, however, a tree is stunted, it may be most advantageously assisted to make wood, as this will in due course spell more profit in the form of excellent fruit. Nothing strong must be given, and whatever is applied should be given when the soil is moist to a depth of not less than 2 feet.

Raspberries.—If abundance of growths may be accepted as indicative of health and vigour in the Raspberry plantation—and there is no reason why they should not—then the plants are now in fine condition, and will yield splendid crops this year and build up strength to bear heavily again next year. It is, however, important that thinning shall be put in hand. It is early as compared with most seasons, perhaps, but this does not alter the fact that it is desirable to put it in hand. Remove all growths that cannot have permanent value in the beds, since the longer they remain, the more food they will draw from the valuable parts of the plants, and the more light and air they will obstruct from the fruiting canes. If the plants have not been mulched, remove all weeds and do the work at once.

Cropping Young Trees.—It is unwise to crop a tree in the first season after planting. One must acknowledge, of course, that the temptation to do so is strong, but it results in stunted growth and consequent failure to build up a tree that will bear profitably for many years. Amateurs should harden their hearts and remove any fruits that are seen, in the certainty that it will be to their ultimate interests to do so. A fruit tree cannot properly establish itself and develop crops at the same time, and the former is the particular object for the first season or two; afterwards the fruits will come.

Mulching Strawberries.—It is necessary that the mulching shall be applied to Strawberry plantations as soon as possible, especially where stained straw is to be utilised. One would not advocate the use of litter containing a large proportion of

manure, because it might not become scrupulously clean before the crop began to swell for ripening, but with slightly-stained material there need be no fear or hesitation on that score. A preliminary to the spreading of the litter is thorough hoeing, as well to remove weeds as to admit warm, fresh air to the roots. Any weeds that cannot safely be removed with the hoe ought to be pulled out by hand. An application of old soot in sufficient quantity to darken the surface often does great good at this time of the year, or, if it is deemed that there is a real lack of readily available food, one of the many excellent concentrated plant fertilisers specially recommended for Strawberries may be used with decided advantage; but care must be exercised to guard against an excess, or far more harm than good will inevitably follow. H. J. W.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS. *The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

PRUNING ROMNEYA COULTERI (H. G. S.).—It is immaterial whether you cut down your plant of *Romneya Coulteri* to the ground or not. It will not be killed by cutting it down, but as the branches are quite healthy there is no reason why it should be so pruned. As a rule, the flowers are rather smaller from plants which have been left unpruned than from those which have been pruned hard, but a great many more flowers are often borne by unpruned specimens. We therefore advise you to simply shorten any weak side shoots and the point of branches which may be dead. A surface-dressing of well-decayed manure may be given with advantage.

SEEDS FOR SHRUB BORDER (Dolphin).—It would have assisted us in giving a selection had you stated the width of the border, since the plants suited to one 3 feet wide would be a little out of place in one twice that width. There is, however, a great variety, ranging from those of a few inches to others of 6 feet or more; of dwarf ones, *Nemophila insignis*, *Candytuft* in colours, *Godetia*, *Linum sanguineum*, *Placelia campanularia*, *Alyssum maritimum*, *Dianthus Heddewigii*, *Leptosiphon*, *Limonanthus Douglasii*, *Sedum album*, *Love-in-a-Mist*, *Alonsoa Warscewiczii*, *Dimorphotheca aurantiaca*, *Convolvulinum*, *Chrysanthemum cernuum*, *C. coronarium* (both in variety) and many more. Poppies, too, would be showy, and Sweet Sultans would give colour and fragrance. The whole of these could be sown in the open ground, and none exceeds 2 feet in height in the ordinary way.

ANEMONE HEPATICA (E. F.).—It is doubtful whether you will be able to obtain seeds of *Anemone Hepatica*, although one of the large firms of seedsmen, such as Veitch, Webb, Sutton, or Carter, may be able to procure them for you if they do not catalogue them. You would, however, do much better by obtaining the dried roots later on and starting with them. They may be secured through any of the large bulb-dealers. Suitable bulbs for the ground beneath your Oak and Birch trees are *Narcissi* in variety, particularly the varieties *Emperor*, *Empress*, *Leedsii*, *Poeticus* and its different forms, *Barri* conspicuous and the common double *Daffodil*. You may also plant *Crocuses* of various kinds and colours, for they continue to spread and flower well for many years, even where the grass is dense. Where the grass is rather thin, you may also plant *Chionodoxa* and *Snowdrops*. The ordinary common *Bluebell* and the Spanish *Bluebell* (*Scilla hispanica*) are also suitable.

PLANTING FLOWER-BEDS AND VASES (F. F. B.).—We are pleased to hear of the complete success of the Tulip arrangement in the Italian garden. With respect to the summer beds, we think you have rather overdone the *Aubrietia græca*, and between this and the flowering of the *Lilies* in September there will be a big gap. Some Tufted Pansies would have given a more profuse flowering.

The suggestions for Beds A and B will do admirably. For Vase C you might get a big Fau Palm (*Latania borbonica*), and as colour is valuable at this point, bed it around with brilliant *Carmine Celosias* over a ground-work of *Saxifraga hypnoides*, treating the other vase similarly. For Bed D we think you had better apply to such Begonia specialists as Messrs. T. S. Ware, Limited, Feltham, or to Messrs. Blackmore and Langdon, Twerton Hill Nursery, Bath, both firms having strains of these flowers of the highest excellence. These varieties are usually selected to colour by the firms named, and are graded in shades throughout.

ARRANGING BORDER (Regular Reader).—The size of the clump is entirely optional, though in a border of the dimensions you name it would be best to arrange irregular groups throughout, starting, say, with 2-foot-wide masses at the front and 4 feet wide for the others. The good effect at flowering-time will, naturally, depend upon the informality of the groups and the way the colours are blended. In setting out the perennials, for example, avoid arranging colours that approximate to each other. Since of necessity the strong would overpower the weak, two *Delphiniums* or two *Phloxes* whose colour shades are near akin should be well separated, and the same may be said of *Michaelmas Daisies* and many others. As the border is an important one, you ought really to plant to a plan previously arranged, so that the colours would blend. In setting out the groups, carefully avoid repetition, whether of size or form. The groups, whether annuals or perennials, might extend longitudinally to 6 feet or more, running down from a 4 feet boldness to quite a narrow finish. In this way you would create variety of form, a very desirable thing.

TREES AND SHRUBS.

MICROMELES FOLGNERI (J. B.).—*Micromeles Folgneri* is an ornamental tree allied to the *Pyruses*. It is a native of China, and was introduced to this country about twelve years ago. Of elegant habit, it has pendent branches which are clothed with silvery leaves and bear flattened heads of white flowers. The small fruits differ from those of *Pyrus*, principally by having no calyx lobes to the apex.

AZALEAS NOT FLOWERING (E. D. L.).—The *Azalea indica* shoots sent for examination are too weak to produce flower-buds; moreover, the leaves are very dirty, being infested with thrips. Weak growth may have been caused by the cold, unless weather of last summer, or the plants may not have been fed sufficiently last year. The reason for the insect attack is probably due to the plants being kept in too dry and too warm an atmosphere. You had better fumigate the plants with Tobacco or one of the commercial nicotine preparations fortnightly for a time, or syringe them with a nicotine solution now and then. Give weak manure-water occasionally while the new growth is being made, providing the plants are not rotted.

LICHEN ON AZALEAS (Rema).—The moss and lichens on your hardy *Azaleas* can be destroyed by spraying the bushes during the winter with a caustic wash. This may be made by taking 2lb. of caustic soda (98 per cent.), half a pound of soft soap, five pints of paraffin and ten gallons of soft water, mixing them as follows: Dissolve the soft soap in one gallon of boiling water, and while hot add the paraffin and stir into a creamy liquid. Dissolve the caustic soda in nine gallons of soft water, and into the solution pour the paraffin emulsion and stir thoroughly. The mixture may only be used when the bushes are dormant, as the soda will burn expanding buds and leaves. India-rubber or leather gloves should be worn while the wash is being applied, and a calm day should be selected for the work.

ROSE GARDEN.

PARAFFIN EMULSION FOR SPRAYING ROSES (L. D. C.).—This can be made as follows: Dissolve one quart of soft soap in two quarts of boiling soft water. Remove from the fire, and while still boiling hot add one pint of paraffin oil and immediately churn the mixture with a small hand syringe. In five minutes a perfect emulsion will be obtained. For use dilute with ten times its volume of water.

ROSE HIAWATHA WITH DISEASED GROWTHS (O. W.).—The warty-like growth upon the shoots of some varieties of *Wichuraiana* roses is supposed to be a fungus peculiar to the tribe. We have not seen any serious harm arise from its presence, and as the growth is one of the best upon the plant, we should advise you to rub off the warty growth and paint the part over with some painter's knotting or liquid grafting-wax.

REVISING ROSE PLAN (R. S.).—There have been many lovely introductions during the last seven years, so that the plan so carefully prepared by our valued contributor Mr. A. R. Goodwin in 1906 will, of course, be open to revision. We would suggest substituting *Cheshunt Scarlet*, *Irish Glory*, *Camoens*, *Kaiserin Augusta Victoria*, *Marquise de Salisbury*, *Mme. E. Bouquet*, *Earl of Warwick*, *Senateur Belle*, *Mme. Edme Metz*, *Ehzabeth Kitto*, *Farbenkonigin* and *Anne Marie Souper* by the following in their same order: *General Macarthur*, *Lieutenant Chauré*, *Mrs. Alfred Tate*, *Molly Sharnum Crawford*, *President Vignet*, *Sunburst*, *Mrs. W. Christie Miller*, *Mrs. Aaron Ward*, *Mme. Segond Weber*, *Lady Alice Stanley*, *Chateau de Clos Vougeot* and *Laurent Carle*. 2. The plan could be reversed to east and west. 3. Climbing roses would look best quite on the outside of the plan. A series of pillars connected by ropes or chains would have a nice effect. 4. You may carpet the beds

with *Violas*, but have one colour to each bed. The blues go well with the yellow *Roses*, white and cream with reds, and so on. By drawing your plan and painting in it the approximate colour of the *Roses*, you could have a nice colour-scheme with the *Violas*.

THE GREENHOUSE.

CHERRY-BLOSSOM FORCED (A. H.).—In common with nearly all hardy fruit trees, the flowers of the *Cherry* can be brought on in advance of the normal time if branches are cut and put in water in a warm greenhouse until the bloom is approaching perfection. The blossom is all the more readily produced if the cut end of the stem is sliced up across and across and the bark raised in three or four strips for a couple of inches, or if the whole end is beaten and crushed with a hammer or mallet on a block. The object of this is to expose a larger amount of woody fibre to the action of the water. There is no need to add charcoal if the water is changed every two or three days.

JAPANESE MAPLE (A. L.).—Judging by the leaves sent, your *Japanese Maple* seems to be in a sorry plight, and we are doubtful if it is not too far gone to revive it. These dwarf trees are the result of what may be termed systematic ill-treatment; that is, they have insufficient room to allow for their natural development, and the soil used is poor in quality. The result of this is that the plant gradually falls into a debilitated condition and is unable to assimilate powerful foods. We should be inclined to turn the plant out of the pot and examine the condition of the roots. It is probable that all the soil will come away, in which case the plant should be re-planted in some good sweet compost. Then place it in a frame kept rather close and shaded, give just enough water to keep the soil moist, and spray overhead two or three times a day.

MISCELLANEOUS.

DUCKWEED IN PONDS (F. G.).—It is improbable that the introduction of gold-fish or carp will keep your ponds clear of *Duckweed*, but it might be worth trying. The best plan is to keep the *Duckweed* raked out as much as possible. This may be done by lining an ordinary sieve with coarse canvas and attaching it to the end of a pole, so using it as a skimmer. In case there is any slime on the water, treat the ponds with copper sulphate as advised to Mrs. E. Fryett in our next week's issue.

APPLICATION OF BASIC SLAG (Amateur).—Basic slag is a valuable manure, as it supplies lime (which counteracts acidity) and phosphates to the soil in a form which plants can use after a time. But it is slowly soluble only, and must be used only in autumn on that account. We should recommend the sowing of the slag, at the rate of, say, 3oz. to 4oz. to the square yard of the surface, just before digging the soil in the autumn. It gives the best results on clay soils, or those containing a good deal of moisture.

LIVING FROM THE LAND (G. W.).—You state your case much more lucidly and satisfactorily in the last letter. It is true that gardeners are often so situated that the education of the children is difficult and sometimes impossible; but the very fact that there are children who must be clothed and fed as well as educated must make one pause in advising the step you propose. You have knowledge and practical experience, and these things spell much. Have you the determination to work from dawn to dark for next to nothing, for it means that until your crops are at perfection? Have you a wife who will be ready—nay, anxious—to help you in your work both before and after the household tasks are commenced and finished? If you can answer the question about yourself with an emphatic "Yes," and that about your wife with an equally emphatic "Yes," go ahead and you will succeed. If you have even the slightest doubt on either or both points, rest contented where you are, for the contemplated chance can only end in disaster. If you desire to proceed, keep enough cash for six months, and bear in mind the importance of fast-growing plants which will bring early and certain revenue. The district you mention is excellent.

VARIOUS QUESTIONS (D. H. S. S.).—There is really very little difference in value between tarred twine and shreds for securing fruit trees to walls; but twine is, of the two, likely to cause more injury to the trees, for if it is tied rather tightly in the first place and not looked to in a few months' time, it is likely to cause injury by cutting into the branches. *Narcissus pallidus* would probably grow under *New Trees* in places where the shade is not very dense. It is, however, a matter for experiment. The plant does deteriorate in some gardens, as you suggest, especially when planted in permanent positions. The common double *Daffodil* and *Emperor* thrive among *St. John's Wort*. It would not, however, do to cut the *St. John's Wort* down before the bulbs begin to grow; rather, plant the bulbs in clumps and let them grow through the *Hypericum*, cutting the latter down about the end of March or early April. It is probable that your soil is too cold and heavy for *Spiraea Thunbergii*. It thrives most satisfactorily in a moderately light, well-drained, warm loam, and flowers better after a warm than after a cold summer. Aspect is not of great moment. You cannot do much good by giving your *Magnolias* chemical manures. You would do better to remove some of the chalky soil from about the roots and replace it with good, sweet loam to which a little peat and leaf-mould has been mixed.

NAMES OF PLANTS.—W. T.—The Bird *Cherry* (*Prunus Padus*).—*A. S. F., Lynnmouth*.—*Rhododendron indicum amonum*.—*Miss I. V. C., Hants*.—*Amelanchier alnifolia*.—*Mrs. H. T. B., Bromyard*.—*Sedum roseum*.—*J. C. H., Blaugourie*.—*Pulmonaria officinalis*.—*G. D., Poole*.—*Prunus Padus* (the Bird *Cherry*).

SOCIETIES.

NATIONAL ROSE SOCIETY.

For the first time in the history of this society a spring show of *Roses* was held this year. The exhibition took place on May 1 in the Royal Horticultural Society's Hall at Vincent Square, and by a general consensus of opinion it was considered a great success. All of the exhibits were competitive, and competition was keen in most of the classes. Throughout the afternoon the hall was thronged with visitors, all deeply interested in this first spring show of the *Queen of Flowers*.

NURSERYMEN'S CLASSES.

Class 1, for a group of pot *Roses*, comprised the finest groups in the exhibition. The first prize and gold medal fell to the lot of Messrs. Paul and Son, The Old Nurseries, Cheshunt, who arranged a superb collection of such varieties as *J. B. Clark*, *Marquise de Sinety*, *Cherry Ripe*, *Mrs. Aaron Ward*, *Mme. Edme Metz* and *Mme. Segond Weber* as a ground-work, arising from which were weeping standards of *Lady Gay*, *Cuckoo's Mate* and *Minnehaha*, with columns of *Dorothy Perkins* and *Excelsa* in the background. The second prize went to Messrs. Hobbies, Limited, Norfolk Nurseries, Dereham, for a massive group of ramblers and weeping standards, which, unfortunately, were much overcrowded. Two trained specimens of *Tausendschön*, profusely flowered, were among the best things in the show, but were somewhat lost in this overcrowded group. Mr. A. Turner, Slough, was third.

In Class 2, for a group of pot and cut *Roses*, Messrs. A. J. and C. Allen, Earham, Norwich, won the first prize in keen competition. The weeping standards of *Excelsa*, *Dorothy Perkins* and *White Dorothy* were all that could be desired. Second, Messrs. B. R. Cant, Old Rose Gardens, Colchester, whose group contained the showy *Austrian Yellow* and a new climbing *Rose* named *Sweet Pea*. Third, Messrs. William Cutbush and Son, Highgate, N., for a group in which the *Polyantha* *Roses* *Jessie* and *Mrs. F. W. Flight* were much in evidence.

There was keen competition in Class 3, for a group of cut *Roses* in a space 20 feet by 3 feet, resulting in equal firsts and silver medals for Messrs. G. Mount and Sons, Limited, Canterbury, and Mr. G. Prince, Oxford. Mr. Prince's ramblers were remarkably fine, and *Rayon d'Or* and *Lady Hillingdon* were used with telling effect. Messrs. Mount's ramblers were not good, but this was more than compensated for by the superb collection of *Sunburst*, *Richmond*, *Mrs. Herbert Stevens* and *Mrs. John Laing*, all shown in the height of perfection. The third prize was won by Messrs. Benjamin R. Cant, Old Rose Gardens, Colchester. *Silver Moon*, a large white single, was much admired in this group.

In Class 4, for eighteen standard *Roses*, twelve varieties, the first prize and silver-gilt medal were won by Messrs. Paul and Son; second, Mr. A. Turner, Slough.

Messrs. Paul and Son secured the first prize and were the only exhibitors for nine weeping standards in pots. The same firm was first for Dwarf *Polyantha* *Roses* in pots; second, Mr. A. Turner.

Messrs. A. Dickson and Sons, Newtownards, were awarded the first prize and gold medal for nine pots of new *Roses*. Two superb novelties from this firm received gold medals, and will be found in the list of new *Roses*. The same exhibitors were first for twelve blooms of new *Roses*.

CUT BLOOMS IN EXHIBITION BOXES.

In Class 8, for thirty-six blooms in not fewer than twenty-four varieties, the first-prize collection from Messrs. B. R. Cant aroused the admiration of all who saw them. Among the best blooms were *Bessie Brown*, *Mrs. E. Mawley*, *Claudius*, *Souy*, *de Pierre Notting*, *Suzanne Marie Rodocanacchi*, *William Shean* and *Colcesteria*. There was no second prize awarded.

Messrs. A. Dickson and Sons were first for eighteen blooms, followed by Mr. G. Mount.

There were no entries in the class for twelve blooms of *Maréchal Niel*.

AMATEURS' CLASSES.

For a group of pot *Roses* in a space of 40 square feet, the first prize and gold medal were secured by Mr. J. Brown, Longfield, Heaton Mersey, Manchester, with a remarkably well-grown collection, including *Mme. Ravary*, *Mrs. R. G. S. Crawford*, *Mrs. John Laing* and *Richmond*, backed with pot ramblers. The plants were healthy and well flowered, and the group was in every way a credit to this exhibitor.

For a group of cut *Roses* 4 feet by 3 feet, Mr. Gordon Clark of Leatherhead secured the first place and a silver-gilt medal for a meritorious group, Mr. H. R. Darlington, Potter's Bar, being a good second.

Mr. Darlington was first for six blooms in not fewer than four varieties, with *The Bride*, *Bridesmaid*, *Dean Hole* and *Souvenir de President Carnot*.

For six blooms of any one variety, the first place was secured by Mr. C. S. Gordon Clark, Leatherhead, with a fine half-dozen of *Frau Karl Druschki*.

For a basket of cut *Roses*, Mr. Conway Jones of Gloucester was a capital first; Mr. J. Brown, Heaton Mersey, second. Mr. Brown was first in a similar class for any number of varieties, and again for five distinct varieties in vases.

For a vase of cut *Roses*, open to ladies only, Miss West, Wray Park, Reigate, was first with a fine vase of *Richmond*. Mrs. Courtney Page, Enfield, was second with *Sunburst*.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Our Special Chelsea Show Number.—In response to the request of numerous readers, who much appreciated our Chelsea Show Number last year, we shall next week publish a Special Double Number containing an illustrated review of the Royal Horticultural Society's Spring Show to be opened at Chelsea on May 20. This issue will be twice the ordinary size, and, in addition to the report of the show, will contain a number of other special features and a coloured plate of the new Rose Danae. The price of this double number will be twopence. As there is certain to be a large demand, we advise those who require extra copies to place their orders well in advance.

Silver-Leaf on Portugal Laurel.—Numerous specimens of Peaches, Plums and Nectarines attacked by silver-leaf have been sent us for inspection from various parts of the United Kingdom. Not uncommonly this disease makes its presence felt on the Portugal Laurel, and without doubt this is a common seat of infection. Where silver-leaf is present in Portugal Laurels, all infected branches should be cut clean out and burnt without delay.

An Interesting Annual Campanula.—As the number of annual Campanulas is somewhat limited, such an interesting one as *C. macrostyla* should receive more attention than it does, and one wonders why it is so little grown. The dull purple flowers, with their curiously-veined markings and prominent styles, make them very attractive. It is quite hardy, and the seeds, which can be purchased quite cheaply, should be sown now where the plants are intended to flower.

Fruit Prospects for 1913.—Judging by the monthly agricultural report just published by the Board of Agriculture, the prospects for fruit this year are good. Blossom nearly everywhere has been abundant, and in most localities severe frost has not been experienced. In those districts where frost did occur about the middle of April, it does not appear to have done any considerable damage. From observations that we have made in the Eastern Counties, Plums have set well, notwithstanding the biting east winds that were experienced when the trees were flowering.

The Southern Heath.—A native of Spain and Portugal, the Southern Heath, *Erica australis*, is a delightful spring-flowering shrub. It is one of the taller-growing species, the bushes ranging from 3 feet to 6 feet high, with rich rosy red flowers, brighter than those of the Mediterranean Heath, from which it also differs in being looser in habit. As it is not perfectly hardy, choose a sheltered spot for the plants, and protect them during severe weather with Bracken or similar light material. When only one or two plants are grown, a good position for them is the base of a warm south or south-west wall. *E. australis* has stood unharmed now for several winters in a large

sheltered bed near the Broad Walk at Kew. During April and early May the flowers are best.

Dwarf Brooms for the Rock Garden.—Few plants are more attractive at the present time with their wealth of blossom than the dwarf Brooms, such as *Cytisus Ardonii*, *C. Bearii* and *C. kewensis*, all of which are excellent plants for the rockery, and if space permits them to ramble about over the stones, they present a charming effect. But if the rock garden is small, the space for them is limited, so that as soon as they have done blooming the wood that has flowered should be cut back to within an inch or so of the previous year's growth, particularly the last two named, as they are of a more rambling nature than *C. Ardonii*. This pruning will not in any way prevent them from blooming the following year.

A New Spraying Mixture.—On May 6, Professor Maxwell-Lefroy of the Royal College of Science and Messrs. Merryweather conducted an extensive experiment in Richmond Park for the purpose of demonstrating the value of lead chromate as a substitute for Paris green for killing various leaf-eating caterpillars. The trees selected for the experiment are situated within a short distance of Ham Gate, and from what is known as Ham Cross Plantation. The group contains some 370 trees, which are about eighty-eight years old and about forty-five feet high. Last year they were defoliated by caterpillars, and caterpillars have appeared again this year. Five kinds are at present feeding, two of the most destructive being *Tortrix viridana* and *Cheimitobia brumata*. The mixture used consisted of 50 per cent. lead chromate, 25 per cent. soft soap, 2 per cent. gelatine and the balance water. One pound of this was then mixed with thirty gallons of water and applied by one of Messrs. Merryweather's petrol spraying-machines. Professor Maxwell-Lefroy has used this insecticide in India with considerable success, and says that it is as great as a deterrent as a poison.

Orchids in Ants' Nests.—As to the reason why certain Orchids find a congenial home in ants' nests, a note in the May issue of the "Orchid Review" by "Rodway" in the case of *Oncidium altissimum* is suggestive. After giving a graphic account of an experience in obtaining this plant, he remarks: "On the fork of a tree the Orchid had found a congenial habitat, where it grew and flourished for years, developing a great mass of roots to be occupied by the immense horde of ants, who, in return for house accommodation, undertook to keep off the enemies of the Orchid, of which the cockroach was one of the most inveterate. . . . Is not this one of the reasons why the ants are so ready to take up their abode among the Orchid roots? Where its food was to be found the cockroach would certainly come, and the ant as certainly find its prey." The benefit may be mutual, and the roots of the Orchid may provide a suitable nesting-place for the ants, as is certainly the case with *Schomburgkia* and *Diannum*.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

A Crippled Pear Tree.—This fine old tree is this year a mass of bloom, in spite of the fact that several years ago it was blown down. I believe it usually crops very well. It is in a field under the shelter of a fell on Lord Muncaster's property in Cumberland.—MARY C. FAIR.

Calceolaria Clibranii.—Extensive use is made of this beautiful *Calceolaria* in the greenhouse at Kew, where it is just now greatly admired. In one part of the structure a semi-circular group arranged on the floor consists of plants from 3 feet to 4 feet in height and as much through, while in another part a number of smaller examples testify to its value when grown in this way. A notable feature of this *Calceolaria* is its graceful habit and soft yellow colour.—H. P.

Tulips Growing in Grass.—The following note may be of service to Mr. Jacob, and at the same time

Garden Clubs.—Pleasant it is to see by my friend the Rev. Joseph Jacob's recent article in *THE GARDEN*, "An Amateur Country Garden Club," page x, issue April 5, that our two countries are awakening almost simultaneously to the benefits and delights sure to follow such special organisations of amateurs as these. Such a club on this side of the water was started twelve years ago by a group of women deeply interested in gardening in the suburbs of Philadelphia, suburbs, without doubt, the most beautiful in this country, and often given the high compliment of the phrase "English-looking"! For some years this garden club went its way alone. Lately, however, in the great gardening fever sweeping over this land, numbers of other garden clubs have arisen in various places with memberships of women, sometimes of men and women, ranging in numbers from a very little garden club in New Jersey, who whimsically call themselves "The Nine of Spades," to a great Connecticut garden club of 200. It is impossible to over-estimate the good that these clubs may do in the highest

elicited by "Alpinist's" questions as to *S. burseriana*, and especially to see that my experience of the plant in Nature seems to be generally borne out in the diverse conditions of culture. The essential danger, in hot, dry situations, is that of uncongenial frizzling, whereas with perfect drainage, good soil and underground watering, there is no doubt that the plant should prove safe in even the most extreme development of the "open situation" that is recommended. I am particularly glad to find that Mr. Hornibrook endorses my opinion and takes up my case. All who have seen his garden well know the value of his horticultural work and advice, and experience of a plant at home (such as increasing years are bringing me) does certainly give great guiding-lines along which to go in culture, so long as those lines are not followed in any minute, slavish, or pettefogging spirit of mere imitation. I wish "Alpinist" could see the tiny *burserianas* on my cliff, which never gets any sun at all. Single rosette cuttings of *Magna* and *Gloria*, tucked into crevices two seasons since, have now from six to eight rosettes apiece, each one of which can faithfully be counted on to emit a flower.—REGINALD FARRER.

— Mr. Farrer's notes on *Saxifraga burseriana* in *THE GARDEN* for April 26, page 202, will be read with interest by every cultivator of this fine plant. Personally, I have no knowledge of this species in its natural habitat, although I enjoy and appreciate the information this distinguished collector furnishes at first hand. I fear, however, there is real danger in translating this knowledge too literally in practice, and we can easily become mere copyists; whereas the value of original travel in disclosing the actual conditions under which a plant grows naturally cannot be other than an approximate guide for an exotic in cultivation, and it does not follow that because *S. burseriana* prefers or frequents some sunless gorge in an alpine valley that it will refuse to grow in a sunny position here, and herein lies the divergence disclosed. That it will grow and flourish in most aspects may readily be proved by anyone who sets himself the task to master the situation; but I contend that *S. burseriana* discloses its highest beauty in an open, sunny spot, free from any and every form of overhead shade. Soil and situation are of greatest moment, and in proof of this, on a natural chalky soil, I have had it give no more trouble than *Aubrietias*, where, beyond the bi-yearly top-dressing, in September and again in spring, it had no further attention beyond an occasional soaking of clear water in an abnormally dry season. Undoubtedly the soil was responsible for this result, and I find that the great majority of rock and alpine plants commonly cultivated appreciate lime in the form of chalk, as, apart from its chemical action, it appears to part less readily with its moisture in summer, while in winter it is relatively warmer and drier than other soils. In the same issue of *THE GARDEN* to which I have already referred, on page 211 Mr. Hyland comments on the behaviour of *Phlox setacea*, but I feel sure, were he to use chalk in equal quantity with his present soil, he would modify his treatment of this fine species and assign it the position it undoubtedly merits in Mr. Farrer's list of the fifty best alpine. I would have little faith in an alpine that requires to be thoroughly watered every day when in full bloom, for plants of this character have little garden value, and, so far as my experience goes, *Phlox setacea* is not of their number.—THOMAS SMITH, *Coombe Court Gardens, Kingston Hill, Surrey.*

A PEAR TREE IN CUMBERLAND WHICH, THOUGH BLOWN OVER, CONTINUES TO FLOWER AND BEAR FRUIT.

of some interest to readers of *THE GARDEN* in general. A batch of *Tulipa sylvestris* was planted here (Ken View, Highgate) in grass under an Oak tree about nine or ten years ago. The first three or four years the plants did very well, but latterly they have dwindled in vigour and floriferousness, until this year only four flowers put in an appearance, two of these being rather small. It is only fair to add that no help or encouragement has been given the bulbs since they were planted. They have not been touched in any way. There is no doubt that the drip from the tree whenever rain fell and the exclusion of the sun by the dense foliage have militated tremendously against their success. In fact, I think they can be said to have made a brave fight to hold their own by yielding four scapes this time; for it has been impossible for them to have had any ripening worth speaking about under a tree, added to which have been the continual splashing from all rains. Grown in grass in the open I can believe this variety would succeed quite well.—C. TURNER.

interests of gardening in America, for the clubs are made up of people of intelligence and taste, people who read, who travel; discriminating and serious amateurs. The Garden Club of Philadelphia has sent out invitations to each of the sixteen clubs of America to a meeting for considering the affiliation of all the garden clubs into a national one, the object of this plan being the exchange of plans for yearly programmes of meetings, papers, speakers and, above all, for the vital thing of which Mr. Jacob speaks—the opening of gardens of members of one club to those of all other clubs. In my experience of the meetings of the Garden Club of Michigan, the one of sixty members with which I happen to be associated, each meeting seems more delightful than the ones past. Enthusiasm runs high, and is applied, not wasted. If any of your readers care to see our by-laws, I will send them with pleasure.—(Mrs.) FRANCIS KING, *Orchard House, Alma, Michigan.*

How to Grow *Saxifraga burseriana*.—I am very much interested in the keen correspondence

The Dropmore Anchusa as a Pot Plant.—I was pleased to see the note by Mr. E. Smith on page 227 of last week's issue on this subject. I have grown this beautiful plant in pots for several years, and can endorse all that he says about it.—B.

Wallflowers Without Fragrance.—May I be allowed space to enter a protest against the floral committee of the Royal Horticultural Society granting an award of merit to a Wallflower in which, as described on page 235 of your issue for last week, "the true Wallflower fragrance is quite lacking in the plant"? In common with many other Fellows of the society, I have hitherto regarded the award of merit as a sort of hall-mark of excellence, denoting that the plant to which it is granted is either an advance on existing varieties or an entirely new species. But a Wallflower without the characteristic fragrance is surely neither of these. So far as I could see, the variety under notice had nothing to commend it. The colour was certainly one that few would care to have in their gardens when so many beautiful and fragrant Wallflowers are obtainable. It is human to err; but if the floral committee of the premier society in the world are going to confer awards of merit on such flowers as this, one's faith in their judgment will be badly shaken. Their aim, and that of everyone else who wishes to forward floriculture, should be to foster fragrance, before all else, in those flowers of which it is a delightful characteristic. Raisers have already thrust upon us scentless Roses and Sweet Peas, and now, backed up by the Royal Horticultural Society, we are to have scentless Wallflowers!—F.R.H.S.

Davidia involucrata Flowering at Kew.—Travellers in Central and Western China have sung the praises of this Chinese tree when in flower so frequently that the fact of its being now in flower at Kew, though only represented by a solitary flower, is worth recording. To Messrs. James Veitch belong the credit of first flowering the tree in this country at their Coombe Wood Nursery in May, 1911, from seeds collected by their traveller, Mr. E. H. Wilson, and sown in April, 1901. Previous to this, in 1909, a plant flowered in France with M. Maurice de Vilmorin at Les Barres. This tree was raised from seed received from Abbé Farges in 1807. The tree flowering at Kew is also from this source, M. Vilmorin presenting it as a small plant in 1901. In the hope of inducing the plant to grow and flower quicker, it was planted when large enough in the centre of the Himalayan House. The *Davidia*, however, is a perfectly hardy tree, there being at least a dozen specimens growing outside in various parts of the Gardens. It is apparently a fairly fast-growing tree, the appearance, particularly the foliage, suggesting a Lime tree. The average height of the trees in China is given as 40 feet to 60 feet. The inflorescence is pendulous, produced on the small side twigs or spurs. The attractive character of the tree lies in the two creamy white bracts, in the centre of which, arising from where they join at the base, are the stamens. An interesting point about these two bracts is that they are unequal in size, one being about double the size of the other, the larger $4\frac{1}{2}$ inches long by $2\frac{1}{2}$ inches wide, the smaller $2\frac{1}{2}$ inches long by $2\frac{1}{2}$ inches wide. The bracts on the trees in China are much larger than this, so no doubt as the trees increase in size in this country the inflorescences will be larger. The *Davidia* belongs to the Natural Order Cornaceae, coming next to the American *Nyssa* trees. In the bracts there is a resemblance to *Cornus Nuttallii*.—D. A.

PRIZES FOR THE BEST ROCK GARDENS.

DURING the next week or two, rock gardens in most parts of the country will be at their best. From letters that we are constantly receiving, we know that a great many owners take a keen interest in these, and their gardeners, in most instances, are also alpine enthusiasts. For some weeks past we have published particulars of prizes that we are offering for three photographs of the best rock garden, or portions of a rock garden, and these details will be found below. We hope as many of our readers as possible will enter this friendly competition, and thus allow others to see what beautiful effects can be obtained by a well planned and planted rock garden.

First prize : Five Guineas, or a Silver Cup of that value.

Second prize : Two Guineas, or Books of that value.

Third prize : One Guinea.

The competition is open only to the actual owner of the rock garden, or to his or her gardener. The object is to encourage good rock gardening, and preference will, therefore, be given to those rock gardens which show originality in design, and where the plants depicted are well grown. It should be distinctly understood that awards will be made to the best rock gardens, and not necessarily to the best photographs. The photographs need not be taken by the competitor, who must, however, in such cases have the written consent of the photographer for their reproduction in *THE GARDEN*. The competition is subject to the following rules :

1. Not more than three photographs of each garden may be sent in by one competitor.
2. Each photograph must have the full name and address of the competitor plainly written on the back in ink.
3. Successful competitors shall furnish written particulars of the rock garden forming the subject of their photographs.
4. Glazed P.O.P. prints must be sent, and each should be on a mount with not more than half an inch margin.
5. All photographs must be sent to arrive at *THE GARDEN* Offices, 20, Tavistock Street, Strand, W.C., not later than June 1, 1913.
6. Unsuccessful photographs sent in for competition will be returned if a sufficiently stamped and addressed envelope or wrapper is enclosed for the purpose, but no responsibility will be taken for the loss or damage of photographs submitted, although every care will be taken to return them uninjured.
7. The Proprietors of *THE GARDEN* reserve to themselves the right to reproduce any photograph sent in for competition.
8. The decision of the Editor will be final.

FORTHCOMING EVENTS.

May 20.—Royal Horticultural Society's Spring Flower Show at the Royal Hospital Gardens, Chelsea (three days).

May 21.—National Tulip Society's Show at Chelsea (two days). Devon County Show at Barnstaple (three days).

May 27.—Rhododendron Show at the Royal Horticultural Society's Hall (four days). Bath and West and Southern Counties Society's Show at Truro (five days).

TREES AND SHRUBS.

THE UPKEEP OF GARDEN HEDGES.

A PART from the necessary clipping which is required to keep a hedge neat, there are other matters that require regular attention if the hedge is to be kept in the pink of condition. These little matters are, unfortunately, often neglected, and the hedges suffer in consequence. A fertile source of trouble connected with hedges is the growth of various weeds of both herbaceous and shrubby character, which sprung up about the bases and ultimately create gaps. Grasses of various kinds are disastrous to a good dense bottom, and one of the most elementary conditions regarding good hedge culture is to keep the bottom free from weeds. Everyone must have noticed the difference in strength between well-cleaned and dirty hedges, yet the cleaning is often considered too much trouble. This is frequently the case where farm and plantation hedges are concerned, and the condition is not absent in gardens, although the weeds may be of a different character.

Bindweed creates a lot of trouble when it once becomes established in a hedge, and this is perhaps one of the commonest weeds found in garden hedges. It is almost impossible to fork out the rhizomes of the Bindweed from among the roots of the hedge, but it may be eradicated by patience. The best way to clean a hedge of this pest is to keep pulling up the young shoots when they are but a few inches long. By continuing this the plants are gradually weakened, and eventually die out. It is a tedious job, but well worth the trouble. A boy could easily perform the work by looking over the hedges once a week. The writer knows of a dense Holly hedge which was being ruined by Bindweed and was cleaned in this way. Couch Grass and Nettles are other subjects that play havoc with hedge bottoms. These are best dealt with by forking out the rhizomes, and then keeping all young growths cut off regularly with the hoe. Once such rubbish is removed, the hedge improves in health in a remarkably short space of time, and holes about the bottom begin to fill up.

Brambles, Hops, Honeysuckles, Elm suckers, Bryony, Traveller's Joy and the Bitter Sweet are coarse-growing subjects that cause serious injury to hedges, and whenever such are noticed they should be removed at once, not left until they have smothered a few yards of hedge before being dealt with.

How to Fill Up Gaps.—Gaps about the bottoms of hedges may be dealt with in a variety of ways. Where there is room to insert a young plant, that should be done; but where this would be impossible, branches should be trained across the opening. Should such openings be used by animals, such as dogs, cats and rabbits, strong stakes should be driven in to prevent access, or if that is impossible, wires should be fastened across, for if the animals are able to use the gaps, there is little chance of the branches growing up. When the bottom of the hedge is very weak, it may sometimes be strengthened by cutting a foot or so off the top, thereby infusing more vigour into the lower parts. In the same way a very wide hedge which is becoming thin in places may often be improved by cutting the sides in well. Such vigorous cutting is best performed during late winter or early spring, for then a full growing season is obtained, whereby

the ugly look inseparable to a hard-pruned plant is soon over.

Manuring.—Hedges which are showing signs of weakness may be rejuvenated by applying a dressing of manure to the roots. Care must be taken, however, to let the manure extend for at least 2 feet from the centre of the hedge on either side. Farmyard manure should be chosen whenever possible, but bone-meal or fish manure may also be used. The former should be spread over the surface of the ground and be lightly forked in, and the same remarks apply to bone-meal; but fish manure is best mixed in water and given in a liquid state as follows: Take 7lb. of the manure and mix it with thirty-six to forty gallons of water, and apply in April and again in July.

Holly and Thorn Hedges are often troubled with aphides of various kinds towards the end of June or July. Such attacks may be dealt with by syringing the hedges with a nicotine or paraffin wash. As a rule, if a hedge is syringed twice, at intervals of a week or ten days, it is quite sufficient to effect a remedy. More difficult to deal with is the Holly fly, which is responsible for the disfiguring yellow blotches which occur on Holly leaves in so many parts of the country. The blotches, or galls, are caused by the larvæ, which feed and afterwards pupate beneath the epidermis of the leaves. The mature insects escape from the galls about May and proceed to lay eggs as the new leaves appear. By syringing the hedges with a paraffin or nicotine wash occasionally during late April and May, many insects may be killed; while by spraying the young foliage with a weak paraffin wash, with a little infusion of Quassia chips added, the leaves are made distasteful to the insects and fewer eggs are laid.

Thin and Tall Hedges which have become gaunt and are generally thin, but otherwise healthy, and more particularly Thorn hedges, may be rejuvenated by laying. This is done in winter-time by cleaning all rubbish from the bottom, then cutting each stem three parts of the way through and laying it down lengthwise, securing it to two or three strong stakes driven into the line of hedge. This is done throughout the hedge. Rough brushwood is cut away until the hedge is of a uniform density, and in the space of a year or two a vigorous hedge results. In some districts garden and farm labourers are very expert at this kind of work, and competitions in hedge laying are held each year somewhat after the fashion of ploughing matches.

Clipping Hedges.—In conclusion, it is very necessary that hedges should be properly and regularly clipped if they are to remain in good condition. It does not so much matter whether a hedge is clipped in June or August, providing one clipping only is given; but it must have that clipping, and when hedges are kept very neat, two clippings, one in June, the other in August or September, are required. In some places even Privet may require to be cut three times during the season.

THE GREENHOUSE.

GROWING CYCLAMEN FROM OLD CORMS.

IT is essential to give most bulbous plants a resting period at some time during the year. Cyclamen are, however, an exception to the rule, though this fact is not generally known. Some growers certainly have a good share of success by gradually drying the corms for a time under various systems best known to themselves. At the present time many good gardeners treat the Cyclamen as an annual, and throw the plants away after once flowering. There is, and always has been, such an uncertainty about growing on from old corms that this is, no doubt, the reason so many have adopted the annual system.

THE PREMIER ALPINE AURICULA, PHYLLIS DOUGLAS, SHOWN BY MR. C. F. FAULKNER AT THE NATIONAL AURICULA SOCIETY'S SHOW (NORTHERN SECTION).

Cyclamen are so useful in winter as cut flowers for table decoration, especially the salmon shades, and nothing can beat them for creating a brilliant show in the greenhouse, or good specimens for rooms, that a little experimenting is well worth the labour. When the plants have finished blooming, if one is knocked out of the pot it will be found that the roots round the side are quite active, and that the growing point or corm is very prominent. Now shake off all the soil and examine the base of the corm, and numerous strong young roots from a quarter of an inch to half an inch long will be found ready to strike down into the soil in search of food. A corm on examination the other day was found to be emitting thirty young roots; this strongly suggests that there must be no drying off, but encouragement given

for an active and immediate growth. The course to take now is to select the requisite number of healthy plants that have just finished flowering. Now comes an operation that looks most unnatural and cruel, which will, no doubt, be looked on by some with suspicion; that is, to sharply jerk off all the leaves by taking each singly with the finger and thumb and giving a sharp pull, which will sever the stalk at the union with the corm. Next knock the plants out of the pots, shake every particle of soil from the roots, and pot the corms in 3½-inch or 4-inch pots, which must be clean and dry. Place one large crock in the bottom and pot lightly, at the same time shaking the soil well in among the roots. A light diet is all that is necessary at this stage, and a sandy loam, with the addition of a little leaf-soil or peat, forms a nice compost. Give the newly-potted corms a good watering with a rosed can, and place them where there is a little

heat, at the same time close and shady. A newly-started vinery or Peach-house or mild hot-bed are all suitable places. Almost immediately growth will commence quite strong. The plants must then be sprayed over twice daily, and in a short time they will be sufficiently well rooted to be potted into their flowering pots. Soil that has been left over from Chrysanthemum potting forms a good mixture, with the addition of more sand and peat or leaf-soil. From now till October stand them in a shady, moist frame, water and ventilate carefully, also spray twice daily till they are housed and the flowers commence to show, when overhead spraying must cease. There must be many who have old corms at the present time; and if a few are grown on as described, a rich harvest of bloom on well-toliated plants will be the reward during months of the year when a little warm colour is most cherished.

D. LEWIS.

Tolley Hall Gardens, Sheffield.

ANNUALS FOR GREENHOUSE DECORATION.

OF late years the different forms of *Nemesia* have come largely to the front, not only for the embellishment of the outdoor garden, but also, when grown in pots, for the decoration of the greenhouse or conservatory. Anyone at all sceptical of their value for pot culture would have had an eye-opener at the meeting of the Royal Horticultural Society on April 15 in a large group of the different forms shown by Messrs. Veitch of Chelsea. The usual method of growing *Nemesias* in pots is to have more than one plant in a pot, and the result is not always a pleasing one. They may in this way flower profusely, but the plants have always a crowded appearance, and, furthermore, where a certain amount of variation exists, the masses of flowers have a somewhat patchy look.

In the case of those referred to, only one plant was grown in each pot (a 5-inch one), and the specimens so obtained were as near perfection as possible. Each plant had been stopped two or three times, and this mode of treatment proved in every way satisfactory. In order to obtain flowering examples thus early in the season, the seed should be sown in the autumn, and the resultant plants treated much as the first batches of

Schizanthus are; that is, grown in a light position, with plenty of air during the winter, but at the same time keeping them quite free from frost. An excess of moisture must at that season be avoided, but, at the same time, they should not be allowed to become dust dry. If shifted into their flowering pots about the middle of February, the young plants will, with the return of spring, have made rapid headway. An important feature in connection with these Nemesis—and, in fact, with many other annuals—is that, by varying the time of sowing, a succession of flowers is kept up for a lengthened period. Another point is the extreme variability which now exists among them, not only in the colour of their blossoms, but also in the size thereof.

The small-flowered class, usually referred to as the Gem section, are remarkably neat in growth and profuse in flowering. Of coloured varieties we have White Gem, Yellow Gem and Blue Gem, this last being, I think, the more generally admired. The flowers of this are of a soft Forget-me-not blue, a charming tint, and one which is at a little distance difficult to verify.

The varieties of the grandiflora strain cover a wide range of colour, the various golden, orange and mahogany tints being very striking, and unusually attractive to the fair sex by reason of their being now such fashionable colours. Besides these, the scarlets, carmines and crimsons are equally showy. Considering that seed, even of the best forms, can be obtained so cheaply, and by growing the plants singly a very small amount will go a long way, the pot culture of Nemesis, though now largely carried out, should be considerably extended.

Schizanthus.—The main batches of these will be by now in flower, and a grand effect they have in the greenhouse when at their best. The distinctive markings of the blossoms of many of them have led to their popular name of Butterfly Flowers, which is certainly a very appropriate one. The

different forms of Schizanthus may be grown in various ways. In the first place, good bushy examples of some of the more compact varieties may be grown in 5-inch or 6-inch pots, while taller specimens of the stronger kinds are exceedingly useful where the scheme of decoration is on a bolder scale. Besides this, the Schizanthus is a valuable basket plant, and in this way the large overhead masses of flowers show it in a very favourable light.

Clarkias.—Treated as the Schizanthus the first flowers of the Clarkias are now open, and under favourable conditions a succession of bloom will be kept up for a long time. Until the last few years the Clarkias were but little grown in pots, but the advent of those delightful forms with blossoms of different shades of salmon and scarlet has led to their extended cultivation.

Mignonette.—The delicious fragrance of its blossoms renders the Mignonette a universal favourite, and until its outdoor flowers can be obtained it is always appreciated in the greenhouse. Sown in autumn, the main point in its culture is to keep the plants growing very slowly, but as sturdily as possible, till the spring. In order to do this, plenty of light and air, with immunity from frost, is essential.

A BADLY CANKERED ROSE STEM.

spraying with Bordeaux mixture from time to time, say, at three or four weeks' intervals, beginning about the end of April or the middle of May.

Rust.—This disease is much more prevalent, as a rule, on Briars than on other Roses, and does perhaps less real harm than those already alluded to. It is caused by the fungus *Phragmidium subcorticatum*, and its first appearance is quite early in the season, in the form of bright orange masses of spores bursting through the bark. They leave cankerous-looking spots on the stems, and, being carried to the foliage, attack it, producing orange or brown and in autumn black spots on the under surfaces of the leaves. These spots are small masses of spores, for the fungus is out of reach inside the leaves. Something may be done by spraying with Bordeaux mixture or with a rose red solution of potassium permanganate in the spring at the time the stem stage is about; but the main thing to do is to destroy the dead leaves on which the black spore masses occur in autumn as soon as possible, and so prevent the infection in early spring, which comes only from these black spores. This fungus is very common on Dog Roses in our hedges, unlike the two mentioned before.

Canker.—In canker we have a stem disease, in which the tissues of the bark down to the cambium are destroyed by a fungus called *Comothyrium Fuckelii*, and a sort of alternate development of callus and destruction of it by the fungus goes on until a large, gaping wound with irregular, thickened edges is produced on the stem. The fungus gains entrance by a wound, and the canker first appears as a purplish dead area on the bark. That is the time to deal with it effectively, and it calls for a surgical operation. Cut out (and immediately burn) the affected part so as to prevent the spores from escaping from the little black fungus fruits, which soon appear on the spot. A wound such as is made by aphides or by one branch pricking another is sufficiently large to permit of the entrance of the fungus, but larger ones afford an easier

ROSE LEAF AND LEAFLET ATTACKED BY "RUST" DISEASE.

THE ROSE GARDEN.

SOME DISEASES OF THE ROSE.

(Continued from page 227).

Black Spot.—The illustration shows admirably the spots or blotches made by the fungus *Actinonema rosæ* on Rose foliage. The branching threads of a dark colour growing inside the leaves and radiating from a common centre may be easily seen with a lens or even with the naked eye. The spores are distributed by rain and wind or on insects' feet, and soon cause the spread of the disease, especially when the plants are in a closely-confined place. Very quickly, when the attack is a bad one, the leaves fall and the trees become almost defoliated. Hybrid Perpetuals perhaps suffer most. In this disease the fungus passes the winter on the fallen leaves or those left on the Roses in mild winters, from which infection spreads in the spring. The collection and burning of these is one method apparently called for, and

ROSE LEAF ATTACKED BY BLACK SPOT.

entrance, and all such made in pruning if over, say, half an inch in diameter should be painted over with either white or red lead paint (without turpentine), or with a 2½ per cent. solution of Lysol. The climbers, especially perhaps those lovely wichuraiana hybrids which in recent years have graced our gardens, seem most prone to attack

F. J. CHITTENDEN.

NEW ROSE MRS. FORDE.

This new Hybrid Tea received the high award of a gold medal at the recent spring show of the National Rose Society. As described in the report of that show in last week's issue, the blooms are pale bluish in colour, of great depth, conical shape, and not without the precious gift of fragrance. The variety possesses a vigorous and erect-growing habit. It is to Messrs. Alex. Dickson and Sons, Newtownards, Ireland, that we are indebted for this promising new Rose.

TREATMENT OF ROSES WITH UNRIPENED WOOD.

Those of your readers who grow Roses may be interested in the following facts and my attempt to explain them. This house is situated on the top of a hill about three hundred feet above sea-level, three miles from the coast and eight miles south of Berwick-on-Tweed. Last winter was more or less mild, with heavy gales and three short, sharp frosts, the hardest being in the first week in December, shortly after my main Rose-planting was completed. It is hardly necessary to tell your readers that we had a very wet summer from the end of May to the end of August. September was fine, though not warm, and October was again wet. November, however, proved an exceptionally good "planting" month. All my neighbours within a ten-mile radius are complaining of the number of Roses, especially ramblers, that have been killed this winter. Every garden seems to have lost dozens. I am glad to say that mine are very healthy, with the exception of twelve three-year-old ramblers, two each of Crimson Rambler, Dorothy Perkins and Lady Gay growing on metal arches. These, though not killed, have been badly cut down, while two contemporary Hiawathas which were on pillars and twelve newly-planted pillar ramblers of various kinds are absolutely intact.

In November last I made some new Rose-beds and remade all the old ones, which necessitated the lifting and heeling in for about three weeks of all the old plants, some two hundred odd. About a hundred were brought from my former home, forty miles south of here, and planted immediately. All the rest were new plants, mostly from the South of France, Devonshire and Essex, and were planted on arrival in November, all

except about a hundred, which were got at the end of December to complete the scheme of my new garden. The two pillar Hiawathas before mentioned were taken up and heeled in for three weeks, as I wished to change their position. The ramblers on the arches were not moved. The sum of all this is that out of 900 Roses, mostly dwarfs, only about a dozen are dead, ten of which are among the new ones I planted late; and the inference I draw from the above facts, on which I invite the opinion of your readers, is this: In a wet season the wood does not ripen well and

ROSE MRS. FORDE, A NEW HYBRID TEA OF PALE BLUSH COLOUR AWARDED A GOLD MEDAL AT THE NATIONAL ROSE SOCIETY'S SPRING SHOW.

the sap continues to run. If an early frost comes and finds these sappy bushes, they are killed. On the other hand, if the bushes have been lifted, the flow of sap is checked, the wood becomes comparatively dry and the frost has no effect on it. Am I to conclude that in order to save one's Roses in a wet season they should all, and especially the ramblers, be dug up and heeled in during the month of November? It seems a laborious remedy, but it is better than losing the plants.

A LADY AMATEUR ROSE-GROWER.

THE FLOWER GARDEN.

DAFFODIL NOTES.

THE outstanding feature of the London Show on April 29 was the fine collection staged by the Rev. G. H. Engleheart. Not that it was so very outstanding in itself, I have often seen his groups when there was much greater variety of type, for on this occasion, as might be expected, the majority were Poets. I have seen them composed of choicer and more uncommon flowers, but I have never before seen him stage one of his accustomed white-robed collections in the annexe after Birmingham. The Lord High Daffodil-maker has this season broken his own records in length (from early March till just upon May) and lateness. I feel sure every Daffodil-lover will congratulate him heartily on this achievement, and, if they had any say in the matter, would unanimously vote him the Royal Horticultural Society's gold medal, which, it is almost incredible to believe, he has never as yet had! We who attend these Daffodil days at Vincent Square have become so accustomed to his wonderful assemblages of lovely blooms that we lose our sense of proportion in our estimation of their value. We forget that most likely when we see them they are lacking some of their choicest jewels, and that those very flowers are possibly the pride of other stands. Emerald Eye at Birmingham, White Emperor and St. Olaf at London are recent examples of what I mean. Suppose some enthusiast got together a collection of Engleheart Daffodils like art committees do with the pictures of some famous painter, what a collection it would be! If arranged on an historical basis, an epitome of the later days of seedling-raising, or if upon merit, it would, at any rate, be a close contest it matched against the world—a sort of Champion County v. The Rest of England. He is always telling me I am fond of Latin quotations. *Salve! magister.*

I felt I must write what I have just written. I now feel more tranquil and prosaic, so that I can call readers' attention to a few of the best varieties that were to be seen on the different stands. First, Evangeline, the beautiful Leedsii that I once called a white Homespun, but which I have since corrected by saying I should have said a "bicolor" Homespun. It is a grand plant, and fully deserved its award of merit. Mr. H. D. Phillips of Olton, a young and keen trade grower, who is fast building up an enviable reputation for delivering "good stuff," was the cultivator of the blooms, and they did him very great credit. It is a plant that *everyone* should have, like Emperor and old Barri conspicuous. Venetia, a fine long-stemmed, cupped pure white triandrus hybrid, raised and exhibited by Mr. Cranfield, also received an award

of merit. These snowy flowers are extremely lovely, but they are very tantalising—easy to raise and flower, but so few with much constitution. It is a great prize when one comes across one that is a good doer; hence I am very glad this particular one got an award. Size, $3\frac{1}{2}$ inches by five-eighths of an inch by 1 inch. Enterprise (Cartwright and Goodwin) was a "useful thing." It is a roundish flower, with a pale primrose perianth and a fairly large eye, with greenish yellow centre gradually suffusing to red. Size, $2\frac{1}{4}$ inches by seven-eighths of an inch.

Sonata (R. H. Bath) was shown in excellent form. It is a "recurvoid" looking bloom, with a pleasing greenish eye edged with a narrow band of red. Size, $2\frac{1}{2}$ inches by five-eighths of an inch. In these days, when there are so many Poets very similar, it is no small recommendation to say of any one that it is distinct. Sonata is. It is exceptionally lovely, too—goodness and good looks.

A Daffodil Holiday.—Most of us do not think it much of a holiday to rush about from show to show and from garden to garden in our anxiety to see all we can in the short Daffodil season. So this is not what I mean. In the course of the afternoon of the 29th ult., I met Sir Arthur Hort with a small box full of real wildings, picked in a distant Pyrenean valley exactly a week before. They were a regular medley of quaint forms, some quite "pallidus-præcox," others quite "muticus," the quaintest of all being a sort of "length without breadth" Ajax. I measured it and found the trumpet to be $1\frac{1}{4}$ inches long by half an inch wide! Sir Arthur had had a holiday in the Pyrenees, and he very kindly told me where one should go if one wants to have a similar enjoyable experience—to Bareilles, an old-world village four miles from the railway station of Arreau. Someone may think it worth while doing another year. It is a fascinating idea: a week where Daffodils grow like Daisies.
